Because dimethylformamide (DMF) is a suitable solvent for coupling reactions in peptide chemistry, mohair was treated with 3,4,5-triiodobenzoic acid *p*-nitrophenylester in DMF for 120 h at 50° C In these conditions, 80 per cent of the ε-amino groups were acylated (DNP analysis) The meridional photometer curve of the X-ray pattern of this sample is shown in Fig 1*b* There is a relatively strong intensification of the 39 Å reflexion in comparison with the unstained sample (Fig 1*a*)

In addition to the ester which was labelled with iodine we also used one which was labelled with mercury, as mercury has a smaller absorption factor and a higher atomic scattering power than iodine *p*-(carboxymethylthiomercury)benzoic acid *p*-nitrophenylester was synthesized according to Matyash and Stepanov[2] When the ε-amino groups were acylated with the mercury compound a partial decomposition of the mercury organic compound occurred

The best method of acylation which we have found consists of treating mohair with *p*-(carboxymethylthiomercury)benzoic acid *p*-nitrophenylester in DMF for 24 h at 60° C In these conditions only 65 per cent of the ε-amino groups are acylated (DNP analysis) but no decomposition is observed In the X-ray pattern of such a sample (meridional photometer curve in Fig 1*c*) there is also an intensification of the 39 Å reflexion, but the representation of this pattern in other reflexions is more comparable with that of the unstained sample Molybdenum disulphide powder was used as an internal standard (6 15 Å reflexion)

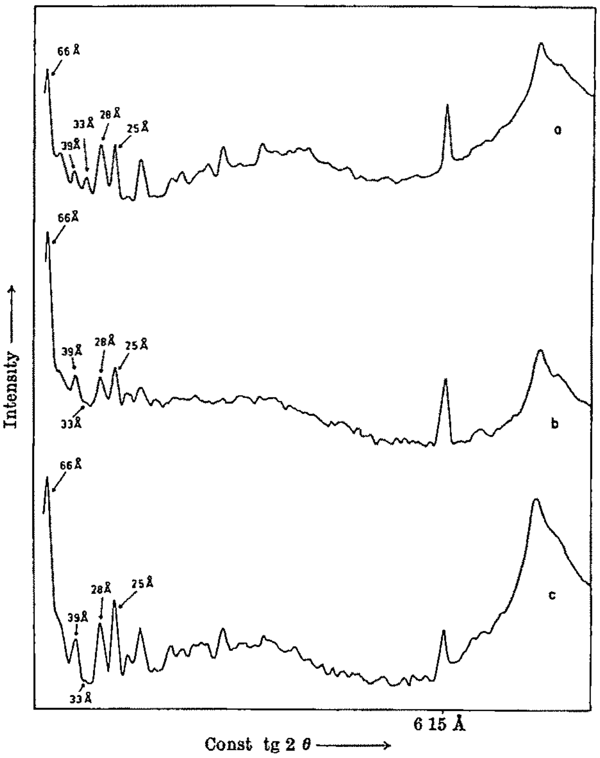

Fig 1 Meridional photometer curves of the low angle X-ray diffraction patterns taken at room temperature with nickel-filtered CuKα radiation *a*, Unstained mohair CSFH , *b*, mohair CSFH stained with 3,4,5-triiodobenzoic acid *p*-nitrophenylester in DMF for 120 h at 50° C, *c*, mohair CSFH stained with *p*-(carboxymethylthiomercury)benzoic acid *p*-nitrophenylester in DMF for 24 h at 60° C

We wish to thank Professor H Zahn for his interest, Dr H Beyer and Mrs U Schenk for DNP analysis, Miss A Augenadel and Mrs K Neumann for technical assistance This research was supported by a grant from the US Department of Agriculture The mohair was provided by the Mohair Board of South Africa

CHEMISTRY

Novel Facilitation of Peptide Synthesis

THE "solid phase" method of synthesizing peptides[1], in which the carbon-terminal residue is first esterified to a hydroxymethylpolystyrene resin, has been used successfully for the rapid synthesis in high yield of peptides which can be purified after removal from the resin[2] If such a procedure, which omits the purification of intermediates, is to yield a homogeneous product without

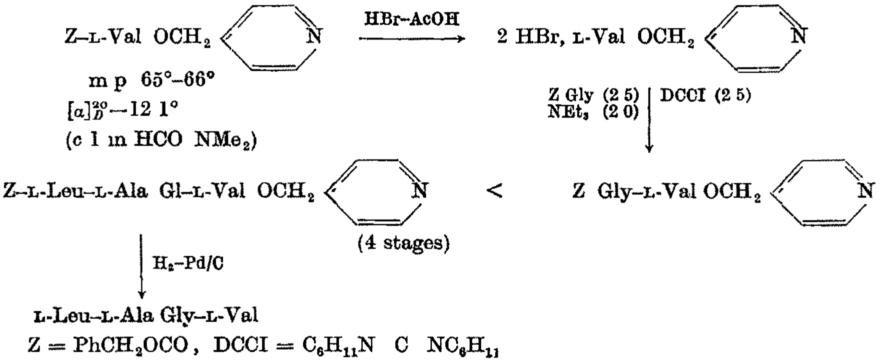

Fig 1

further purification, every stage must proceed to completion For example, if 0 5 per cent of the amino-groups remain unacylated after each coupling, then after one hundred stages the product will contain only 61 per cent of the required peptide, the remainder being peptides with closely similar but defective sequences It is a serious disadvantage of the solid phase method that one of the reactants is polymeric, making it difficult to force reactions to completion

We are examining a fundamentally different procedure in which reactions are carried out in solution and the protected peptide is then adsorbed on an ion-exchanger while the excess of acylating agent and the co-products are washed away For this purpose, a weakly basic group has been incorporated in the carbon-terminal residue by using its 4-picolyl ester (prepared from the reaction of the benzyloxycarbonylamino-acid triethylammonium salt with 4-picolyl chloride in dimethylformamide), these esters are stable to hydrogen bromide in acetic acid at room temperature but are cleaved by catalytic hydrogenation The method[3] is illustrated by the synthesis of L-leucyl-L-alanyl-glycyl-L-valine, as outlined in Fig 1 In the coupling reactions, 2 5 molar proportions of benzyloxycarbonylamino-acid and of dicyclohexylcarbodi-imide (relative to the amino-component) were used in tetrahydrofuran solution After filtration to remove dicyclohexylurea, the coupling product was taken up on moist sulphoethyl 'Sephadex' (*C*-25, H$^+$ form), which was then washed thoroughly with tetrahydrofuran. The benzyloxycarbonylpeptide 4-picolyl ester was next eluted with 2 per cent triethylamine in aqueous tetrahydrofuran, and after evaporation of the solvent the benzyloxycarbonyl group was removed by treatment of the residue with 3 5 normal hydrogen bromide in acetic acid. The peptide ester dihydrobromide was precipitated with ether, and again from ethanol by ether, and the cycle was repeated After the final hydrogenation in 80 per cent acetic acid, the solution was evaporated and the residue was dissolved in ethanol and precipitated by ether Without further purification, the crude tetrapeptide monohydrate (60 per cent yield overall, from L-valine 4-picolyl ester dihydrobromide) was analytically and chromatographically pure, no alanylglycylvaline or glycylvaline could be detected by thin-layer chromatography which (in control experiments) could detect 0 2 per cent of these impurities Amino-acid analysis of an acid hydrolysate gave the ratios· Leu, 0 96, Ala, 0 97; Gly, 1 00; Val, 1 00 A more sensitive test of the completion of each coupling stage was obtained by thin-layer chromatography of the intermediate benzyloxycarbonylpeptide 4-picolyl esters (a check not available in the solid-phase procedure), in every case, in conditions which will detect 0 1 per cent of the corresponding amino-component, none was found The same tetrapeptide was obtained using *p*-nitrophenyl esters (4 molar proportions) for coupling (65 per cent overall yield of protected tetrapeptide) The specific rotations of the final products, $[\alpha]_D^{20}$ + 22 5° (*c* 1–2 in ethanol) (dicyclohexylcarbodi-imide method), + 23 7° (*p*-nitrophenyl ester method), are higher than those reported previously[1], $[\alpha]_D^{21}$ + 17 5°, + 18 0°, but the tetrapeptide (dicyclohexylcarbodi-imide method) was completely hydrolysed by leucineaminopeptidase (Leu, 1 00, Ala, 0 88, Gly, 0 98, Val, 1 04), and hydrogenation of the intermediate benzyloxycarbonylglycyl-L-valine 4-picolyl ester gave fully active glycyl-L-valine A trace of a ninhydrin-positive contaminant, apparently arising from the 4-picolyl residues, always appeared in the products of hydrogenation of the picolyl esters, it is soluble in organic solvents and is therefore readily removed from normal peptides This tetrapeptide is, however, unusually soluble in these solvents, and the contaminant was removed during drying at 100° C and 1 mm mercury The protected tetrapeptide 4-picolyl ester was converted into the crystalline hydrazide by means of hydrazine hydrate, and this route should enable components which have been synthesized independently to be united through the acid azide As a further variant, picolyl esters may be converted into amides in the usual way, and this should provide convenient syntheses of peptides having a carbon-terminal amide group Such possibilities are now being examined

Ultraviolet Photolysis of Sodium Nitrate Solutions in the Laboratory and by Sunlight

CHEMICAL processes, induced by ultraviolet light in some aqueous inorganic nitrates, are of substantial interest in the chemistry of atmospheric aerosols Nitrates form a large fraction of the inorganic natural aerosol[1] and, although they might be expected to decompose under sunlight[2], no systematic work on such photolysis has, as yet, been reported.

Earlier work on ultraviolet reduction of nitrate to nitrite was done by Villars[3] and Cultrera and Ferrari[4-6] The effect was confirmed by others[7-10] and also in this laboratory, where it was found to be accompanied by the formation of highly oxidizing intermediates[11], and it was also found that the formation of nitrite is caused by primary steps in which higher oxides of nitrogen are involved[12-15] The process of nitrite formation during photolysis of nitrates is reproducible as long as the solution is properly stirred[11], because stirring ensures the removal of gaseous reaction products from the zone below the interphase where penetration by ultraviolet light is possible. Our quartz cell (Fig 1) had an overall capacity of 140 ml and was rigidly supported on a rack which oscillated mechanically thirteen times per min about its horizontal position Because the cell initially contained 110·0 ml of nitrate solution, a bubble of air helped to mix the solution and remove the gas The rack supported another identical parallel tube filled with 110 0 ml of an actinometric solution, with 1 90 g/l and 1 124 g/l of oxalic acid and uranyl oxalate, respectively[16], which, in our conditions, absorbs in the near ultraviolet in a similar way to nitrates[17] Equal samples (5 00 ml) were periodically taken from both tubes and analysed for nitrite using the Griess reagent[18] and, by titrating with permanganate, the samples were analysed for the amounts of near ultraviolet light absorbed, using a quantum efficiency of 0 56 and assuming full absorption of light[16] Merck's reagent, very pure chemicals and distilled water were used, the results are expressed in terms of original volumes of solutions photolysed

A method was developed for studying the photolysis by sunlight of some aqueous compounds known to exist as natural aerosols Preliminary work involved testing the system sodium nitrate–sodium chloride, on irradiation with a 550 W stabilized high-pressure mercury Hanovia ultraviolet lamp (No 673-*A*) At constant radiation doses of about $2\ 3 \times 10^{21}$ UV quanta per h, the rates of nitrite formation, α, were independent of nitrate concentration in the range of 0 6 to 7 1 mole per l and at *p*H values higher than 5 (ref 18) Nitrite formation increased according to a competitive process

$$NO_2^- = \frac{\alpha R}{1+\beta t} \qquad (1)$$

where R is the radiation absorbed up to time t, and α and β are constant of the experimental run. The term β was found to be dependent on *p*H and stirring and thus on the release of nitrous anhydride from solutions

We have also found (results to be published) that the formation of nitrite is enhanced by the chloride ion, probably because of a stabilization of the nitrogen oxides evolved, by NOCl intermediates In order to test the possibility of occurrence in nature of such photolytic processes, experiments were carried out last summer at different altitudes and on cloudless days Table 1 shows the locations, Fig 2 shows the averaged results Each point represents an average of about eight and five experimental values for nitrate and nitrate + chloride systems, respectively, taken between 8 a m and 4 p m Linear correlation coefficients between $\frac{R}{NO_2^-}$ and t (equation (1)), based on about five daily readings and ten and six kinetic experiments spread over different altitudes, yielded root mean square averages of 0 99±0 01 and 0 97±0 03 for sodium nitrate and sodium nitrate–sodium chloride solutions, respectively Because parallel measurements also indicated a good linear approximation between R and t (root mean square correlation coefficient from sixteen values, $r = 0\ 998 \pm 0\ 002$), the right hand side of equation (1) was expressed in terms of parameter R alone

$$NO_3^- = \frac{\alpha' R}{1+\beta' R} \qquad (2)$$

as shown in Fig 2 Values of α′ and β′, corresponding to the plots illustrated, are given in Table 2, "errors" are largely caused by systematic changes of α′ and β′ with temperature (results to be published) Blank tests failed to reveal detectable absorption of NO_X from the air

BIOCHEMISTRY

Sites of Inhibition of DNA Synthesis by Kethoxal *bis*(Thiosemicarbazone)

THE growth of several neoplastic cell lines is inhibited by 2-keto-3-ethoxybutyraldehyde *bis*(thiosemicarbazone) [kethoxal *bis*(thiosemicarbazone), KTS][1-9], an agent which forms tetradentate chelates with metals of the first, second and third transition series In the presence of either copper or zinc ions the antineoplastic potency of KTS is markedly increased, particularly with the cupric chelate [Cu(II)KTS][8-12]

KTS and its cupric chelate primarily inhibit the biosynthesis of DNA The rate of formation of RNA and protein is also depressed by these agents, but inhibition of these latter processes is less pronounced[11,13-15] Although both KTS and Cu(II)KTS decrease the rate of incorporation of several isotopic precursors into DNA, the patterns of inhibition produced by these agents are distinctly different[15] The effects which are induced by Cu(II)KTS in sarcoma 180 ascites cells are characterized by a pronounced decrease in the rate of incorporation of ^{3}H-thymidine into the thymine of DNA and lesser inhibitions of the utilization of ^{14}C-formate, ^{3}H-deoxycytidine and ^{3}H-5,6-uridine for the formation of the pyrimidine nucleotides of DNA The site which is most sensitive to the inhibitory activity of Cu(II)KTS seems to be the enzyme thymidine kinase In contrast, the ligand KTS does not decrease the rate of incorporation of ^{3}H-thymidine into the DNA of sarcoma 180, but causes marked inhibition of the utilization of radioactive formate, deoxycytidine and uridine for the formation of DNA[15] The cellular toxicity of Cu(II)KTS is essentially caused by copper The relatively lipid-soluble Cu(II)KTS complex effectively serves to transport and deposit copper at sensitive sites within cells Thus dissociation of the Cu(II)KTS occurs within neoplastic cells treated with the cupric chelate, this phenomenon is followed by the cellular elimination of the ligand portion of the molecule and the much slower expulsion of copper[15]. Because only small doses of Cu(II) KTS can be administered to animals with tumours, only relatively small amounts of KTS released by dissociation of the cupric chelate are present, thus differences are observed in the biochemical lesions which are induced by Cu(II)KTS and KTS in whole cells The data in this communication describe the inhibition of several enzyme reactions which could account for the inhibition of the synthesis of DNA induced by KTS

Experiments were performed on 9–11 week old female *CD*-1 mice which had been inoculated intraperitoneally 5–6 days previously with 4 × 10^{6} sarcoma 180 ascites cells The activities of dihydrofolate reductase[16], 10-formyltetrahydrofolate synthetase[17], 5,10-methylenetetrahydrofolate dehydrogenase[18] and thymidylate synthetase[19] were measured as previously described Protein was determined by the biuret method Enzyme extracts were prepared from sarcoma 180 ascites cells which were collected through an incision in the peritoneal wall All subsequent procedures were performed at 4° C unless otherwise stated The suspensions were centrifuged at 1,600*g* and the ascitic fluid was discarded The cell pack was washed with five volumes of isotonic saline and was collected by centrifugation at 1,600*g*, contaminating erythrocytes were lysed by the addition of five volumes of 0 2 per cent saline and mixing for 30 sec Five volumes of 1 6 per cent saline were added to restore isotonicity and the suspension was centrifuged at 1,600*g* for 2 min The cell-free extract which was used for the preparation of dihydrofolate reductase was prepared by washing each cell pack with isotonic saline and suspending each in five volumes of 0 5 molar *tris* buffer (*p*H 7 5), cells were lysed by three cycles of alternate freezing and thawing The supernatant solution which was obtained after centrifugation of the lysate at 10,000*g* for 10 min was dialysed for 20 h against two hundred volumes of distilled water 10-Formyltetrahydrofolate synthetase and 5,10-methylenetetrahydrofolate dehydrogenase were prepared from the cell pack which had been freed from contaminating erythrocytes by washing the cell pack) once with four volumes of 0 05 molar *tris* buffer (*p*H 7 5- containing 0 05 molar EDTA The cell pack was suspended in four volumes of the *tris*-EDTA buffer and was subjected to three cyles of alternate freezing and thawing, the supernatant solution obtained after centrifugation of the lysate at 12,000*g* was further fractionated by the addition of ammonium sulphate The fraction which precipitated between 30 and 45 per cent saturation with ammonium sulphate was passed through a column of 'Sephadex *G*-25' to remove the EDTA, using water as the eluant Thymidylate synthetase was prepared from the erythrocyte-freed ascites cells by washing the cell pack once with five volumes of isotonic saline, the resulting cell pack was suspended in two volumes of 0 05 molar potassium phosphate buffer (*p*H 6 7) Cells were lysed by sonication with a Branson sonifier using two 30 sec bursts at an energy setting of 8 amp with a 20 sec period between each burst The sonicate was centrifuged for 1 h at 104,000*g* and the clear supernatant was filtered through glass wool

The incorporation of ^{14}C-formate into the thymine of DNA, a process which is inhibited by KTS, requires the participation of a series of enzyme reactions (Fig 1). The effects of KTS on several of the enzymes which are involved in this pathway are shown in Table 1 Thymidylate synthetase seemed to be the enzyme most sensitive to this agent, a concentration of 0 02 mmolar of KTS caused 66 per cent inhibition, employing the substrate deoxyuridine 5′-phosphate, tetrahydrofolate and formaldehyde at concentrations of 50 mmolar, 0 2 mmolar and 5 mmolar, respectively 5,10-Methylenetetrahydrofolate dehydrogenase was also inhibited by KTS With 1 0 mmolar tetrahydrofolate and 5 mmolar formaldehyde, 0 04 mmolar KTS caused 68 per cent inhibition Dihydrofolate reductase was also sensitive to this agent and a comparable degree of inhibition was attained using 0 05 to 0 06 mmolar KTS in the presence of 0 05 mmolar dihydrofolate and 0 04 mmolar NADPH Preincubation of the cell-free extract with KTS for periods of up to 20 min did not increase the degree of inhibition of dihydrofolate reductase Dialysis against water of the enzyme

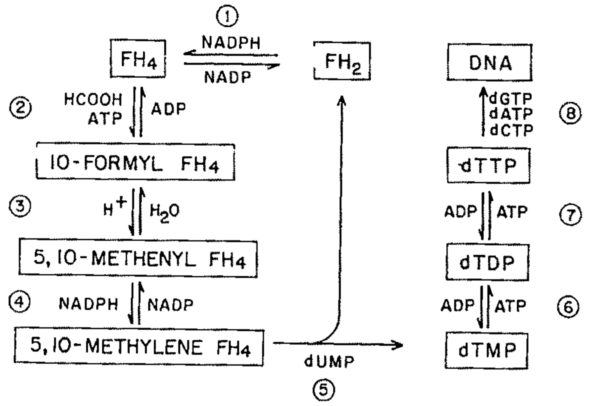

Fig 1 FH_2, Dihydrofolate, FH_4, 5,6,7,8-tetrahydrofolate, 10-formyl FH_4, 10-formyltetrahydrofolate, 5,10-methenyl FH_4, 5,10-methenyltetrahydrofolate, 5,10-methylene FH_4, 5,10-methylenetetrahydrofolate, NADP, nicotinamide adenine dinucleotide phosphate, NADPH, reduced nicotinamide adenine dinucleotide phosphate, ATP, adenosine 5′-triphosphate, ADP, adenosine 5′-diphosphate, dUMP, deoxyuridine 5′-phosphate, dTMP, deoxythymidine 5′-phosphate, dTDP, deoxythymidine 5′-diphosphate, dTTP, deoxythymidine 5′-triphosphate, dGTP, deoxyguanosine 5′-triphosphate, dATP, deoxyadenosine 5′-triphosphate, dCTP, deoxycytosine 5′-triphosphate, DNA, deoxyribonucleic acid The enzyme reactions are depicted (1) dihydrofolate reductase, (2) 10-formyltetrahydrofolate synthetase, (3) 5,10-methenyltetrahydrofolate cyclohydrolase, (4) 5,10-methylene tetrahydrofolate dehydrogenase, (5) thymidylate synthetase, (6) deoxythymidine monophosphate kinase, (7) deoxythymidine diphosphate kinase, (8) DNA nucleotidyltransferase

KTS was dissolved with the aid of ethanol the final concentration of ethanol in the enzyme assays was 1 per cent which was not inhibitory to the activities of these enzymes

* The complete system contained, in a volume of 1 0 ml 100 µmoles of *tris* buffer (pH 7 5), 0 04 µmoles of NADPH, 0 1 ml of enzyme, 0 5 mg of protein, 150 µmoles of potassium chloride, and 0 05 µmole of dihydrofolate, containing 10 µmoles of 2-mercaptoethanol The dihydrofolate was added last to initiate the reaction The decrease in absorbancy at 340 mµ caused by the oxidation of NADPH and the reduction of dihydrofolate was followed at intervals of 15 sec Control activity, expressed as Δ340 mµ/4 min, was 0 21

† The complete system contained, in a volume of 1 0 ml 100 µmoles of *tris* buffer (pH 7 5), 10 µmoles of ATP, 0 1 ml of enzyme (1 0 mg of protein), 20 µmoles of magnesium chloride, 1 0 µmole of tetrahydrofolate containing 10 µmoles of 2-mercaptoethanol and 50 µmoles of ammonium formate The ammonium formate was added last to initiate the reaction The components were incubated at 37° C for 3 min, the reaction was terminated by the addition of perchloric acid and the increase in absorbancy at 355 mµ caused by the formation of 5,10-methylenetetrahydrofolate was determined by comparing the complete system with a reaction mixture without ammonium formate Control activity, expressed as Δ355 mµ/3 min, was 0 79

‡ The complete system contained, in a volume of 1 0 ml 100 µmoles of *tris* buffer (pH 7 0), 1 0 µmole of tetrahydrofolate containing 10 µmoles of 2-mercaptoethanol, 5 µmoles of formaldehyde, 0 1 ml of enzyme (1 mg of protein), and 0 4 µmole of NADP The NADP was added last to initiate the reaction The increase in absorbancy at 340 mµ caused by the formation of NADPH was followed Control activity, expressed as Δ340 mµ/10 min, was 0 13

§ The complete system contained, in a volume of 1 0 ml 500 µmoles of potassium phosphate buffer (pH 6 7), 50 µmoles of deoxyuridine 5′-phosphate (dUMP), 5 µmoles of formaldehyde, 5 µmoles of magnesium chloride, 0 2 µmole of tetrahydrofolate, 30 µmoles of 2-mercaptoethanol, and 0 3 ml of enzyme (3 9 mg of protein) The complete mixture minus dUMP was preincubated at 37° C for 5 min, dUMP was added last to initiate the reaction and the increase in absorbancy at 340 mµ was measured Control activity, expressed as Δ340 mµ/10 min, was 0 05

‖ Not determined at indicated concentrations

which had been treated with KTS completely reversed the drug-imposed inhibition, but neither dihydrofolate nor NADPH afforded protection In contrast to these enzymes, 10-formyltetrahydrofolate synthetase was only slightly inhibited by a concentration of KTS of 0 1 mmolar, when the substrates tetrahydrofolate, formate and ATP were used at levels of 1 0 mmolar, 50 mmolar and 10 mmolar, respectively The findings that the enzymes deoxythymidine mono- and di-phosphate kinases and DNA nucleotidyltransferase were not inhibited by KTS suggest that the blockade of the incorporation of ^{14}C-formate into the thymine of DNA induced by KTS in intact sarcoma 180 ascites cells[15] can be accounted for by inhibition of thymidylate synthetase, 5,10-methylenetetrahydrofolate dehydrogenase and/or dihydrofolate reductase

To determine whether intracellular concentrations of KTS were large enough to inhibit these enzyme reactions, sarcoma 180 tumour-bearing mice were exposed to ^{14}C-KTS (36 6 × 10^3 c p m /µmole) at a level of 200 mg/kg body weight The cellular concentrations of KTS were determined by measuring the radioactivity which was associated with cells exposed to ^{14}C-KTS, the radioactive carbon was present in the thiosemicarbazide portions of the molecule KTS-^{14}C was suspended by homogenization in ethanolic sodium chloride containing 'Tween 80' (ref 15) and was administered to each animal by intraperitoneal injection At selected intervals of time thereafter, ascites fluid was removed from each mouse and the cells were collected by centrifugation for 2 min (1,600g) The fluid was decanted and the packed cells were diluted with four volumes of distilled water, 1 ml of this suspension was solubilized by the addition of a concentrated solution of sodium hydroxide (final concentration, 0 2 normal) A sample was taken for measurement of radioactivity in a Packard 'Tri-carb' liquid scintillation spectrometer using a phosphor solution of p-*bis*-[2-(5-phenyloxazolyl)] benzene and 2,5-diphenyloxazole dissolved in toluene and ethanol[15] Radioactivity equivalent to approximately 2 0 µmoles of KTS was present in each g of cells 2 h after administration of the drug Relatively rapid loss of KTS occurred in these experiments, thus, by 12 h after exposure of the cells to radioactive KTS, about 0 58 µmole of KTS/g remained, and by 24 h each g of cells contained only 0 16 µmole of KTS If it is assumed that the radioactivity present in the cells represents unaltered KTS, that the drug distributes itself uniformly throughout the cell, and that water comprises 75 per cent of the cell volume, the cellular concentration of KTS would be about 2 5 mmolar, 0 7 mmolar and 0 2 mmolar at 2, 12 and 24 h, respectively, after the injection of KTS Thus intracellular concentrations of KTS seem to be achieved which are inhibitory to thymidylate synthetase, 5,10-methylenetetrahydrofolate dehydrogenase, and dihydrofolate reductase The blockade of these enzyme reactions requires the inhibition of the incorporation of both deoxycytidine-^{3}H and ^{3}H-uridine into DNA in cells which were exposed to KTS That such inhibition does indeed occur was shown in an earlier report from this laboratory[15]

We thank Dr Harold G Petering, formerly of the Upjohn Company, for generous supplies of kethoxal *bis*(thiosemicarbazone) and Miss Sheila J Feld, Miss Florence C Dunmore and Miss Lynn A Bon Tempo for assistance This work was supported by a US Public Health grant from the National Cancer Institute

Differences in Isozyme Patterns of Nucleic and Cytoplasmic Lactate Dehydrogenase of Rat Liver Cells

THE resistance of lactate dehydrogenase (LDH) activity to the denaturating action of 4 molar urea in the nuclei of rat liver cells is considerably greater than that in the cytoplasm[1] To investigate these differences we have examined the resistance of LDH to high temperatures and the relationship of temperature to substrate (pyruvate) concentration We have also determined LDH isozymes in starch gel after electrophoresis

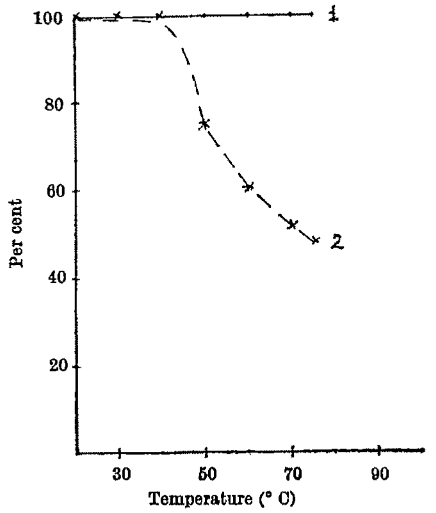

Fig. 1. Effects of heating on LDH activities of nuclear extract and soluble cytoplasmic fraction of rat liver cells. The abscissa gives the temperature (° C), the ordinate gives the per cent of inhibition of LDH activities. 1, Nuclear extract; 2, soluble cytoplasmic fraction.

We used rats weighing between 80 and 140 g. Nuclei and cytoplasm were isolated from perfused rat livers by differential centrifugation in medium containing 0·25 molar sucrose and 0·003 molar calcium chloride. The nuclei were isolated by the technique of Stirpe and Aldridge[2] with a slight modification[3].

The livers from three rats were perfused *in situ* with about 150 ml. of ice cold 0·85 per cent sodium chloride solution, minced finely with scissors and homogenized in a mixture of 0·25 molar sucrose and 1·8 mmolar calcium chloride (one part liver, three parts medium) in a Potter-Elvehjem type homogenizer at a speed of 1,800 r.p.m. The resulting homogenate was diluted to a volume in ml. equal to ten times the weight of the liver in grams with the homogenizing medium and then filtered through two layers of flannelette. The filtered homogenate was then centrifuged for 10 min at 600*g*. The supernatant was pipetted from the sedimented material and suspended in a mixture of 0·25 molar sucrose and 1·8 mmolar calcium chloride. A portion (10 ml.) of the suspension was carefully layered over 20 ml. of a mixture of 0·34 molar sucrose and 1·8 mmolar calcium chloride and centrifuged for 10 min at 600*g*. The supernatant was removed and the sedimented material was resuspended in 5 ml. of 0·25 molar sucrose and 1·8 mmolar calcium chloride. Then 10 ml. of a mixture of 0·34 molar sucrose and 1·8 mmolar calcium chloride was layered under this suspension and centrifuged as before. The final sediment was resuspended in 0·25 molar sucrose and 3 mmolar calcium chloride. All stages were carried out at 4° C.

We did not use 2·2 molar sucrose, although in this medium the nuclei were free from cytoplasmic contamination, because they lost much of the activity of the enzymes associated with the soluble fraction of the nuclei.

In every preparation the nuclei were examined microscopically as smears stained by fast green-aceto-orcein. The nuclei resembled those in the living cells. The preparations were contaminated by a few unbroken cells and nuclear fragments. The nuclei formed quickly into a transparent viscous gel when the *p*H was brought to 9.

The contamination of the nuclear fraction by cytoplasm and whole liver cells was slight: not more than 10 per cent of glucose-6-phosphatase activity of the homogenate was found in the nuclei. The nuclei do not contain glucose-6-phosphatase dehydrogenase as one of the cytoplasmic enzyme markers.

To compare LDH activity in the nucleus and cytoplasm we used a nucleic extract and a soluble cytoplasmic fraction. The nucleic extract was prepared by homogenizing the nuclei in 0·25 molar *tris*-buffer while the soluble cytoplasmic fraction was obtained by centrifuging the remaining supernatant fluid, after the precipitation of nuclei, at 30,000*g* for 40 min. Assays of LDH activity in enzyme preparations were made in an '*SF*-4' spectrophotometer using pyruvate as substrate by decreasing the NADH concentration in solution (340 mμ). The buffer solution used was KH_2PO_4 and K_2HPO_4, 0·05 molar at *p*H 7·5. The assay mixture contained $3·1 \times 10^{-4}$ molar sodium pyruvate, made up in 2·7 ml. of the buffer. $NADH_2$ (8×10^{-3}) molar was made up in 0·5 ml. of 1 per cent sodium bicarbonate and 0·1 ml. of extract and placed in the spectrophotometer cuvette. The change in absorbancy was read after exactly 2 and 4 min at room temperature[4]. To test the effect of substrate concentration on LDH activity the same reaction medium was used except that the substrate concentration was varied within the range $2·5 \times 10^{-4}$—$2·5 \times 10^{-2}$ molar. The extracts were subjected to temperatures of 30°, 40°, 50°, 60°, 70° and 75° C for 15 min.

The technique of vertical electrophoresis in starch gel developed by Smithies[5] was used to resolve the isozymes of LDH. A sample (0·07 ml.) of the extract (30 to 50 mg protein/ml.) was placed on the gel. Electrophoresis was carried out for 15–17 h at 4° C with a voltage gradient of 10–15 V/cm. Usually a borate buffer at *p*H 8·6 and 0·006 ionic strength was used. After electrophoresis the location of LDH activity on the starch gel was visualized by formazan formation[6].

The nuclear LDH activity was more resistant to heating than the enzyme from the cytoplasm. This difference was seen very clearly using the livers of young rats weighing about 100 g. There was a 50 per cent inactivation of the cytoplasmic LDH at a temperature of 70° C, while the activity of the nucleic enzyme remained unchanged at 75° C (Fig. 1). The data on the inhibition of LDH activity by heat and also by the action of urea show that the LDH of the nucleus has a greater resistance than the LDH of the cytoplasm. One of the possible reasons for this is a different isozyme content in the nucleus and cytoplasm. It has been shown that there is a difference in the sensitivity of LDH isozyme to the deleterious effects of low and high temperatures[7-10]. The LDH sensitivity to some factors increases from the first to the fifth isozyme. To support this suggestion about the different LDH isozyme content of the nucleus and cytoplasm the relationship between the enzyme activity and the substrate (pyruvate) concentration was studied. Kaplan *et al.*[11] have shown that LDH isozymes have different substrate optima, and that LDH-1 is more sensitive to large pyruvate concentrations than is LDH-5. Fig. 2 shows that the inhibition of LDH activity in the

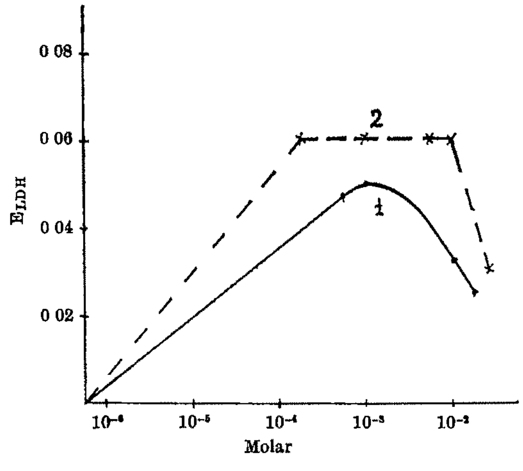

Fig. 2. Effects of different concentrations of sodium pyruvate on LDH activities of nucleic extract and cytoplasmic soluble fraction of rat liver cells. The abscissa gives the sodium pyruvate concentration, the ordinate gives the activity in units. 1, Nuclear extract; 2, cytoplasmic soluble fraction.

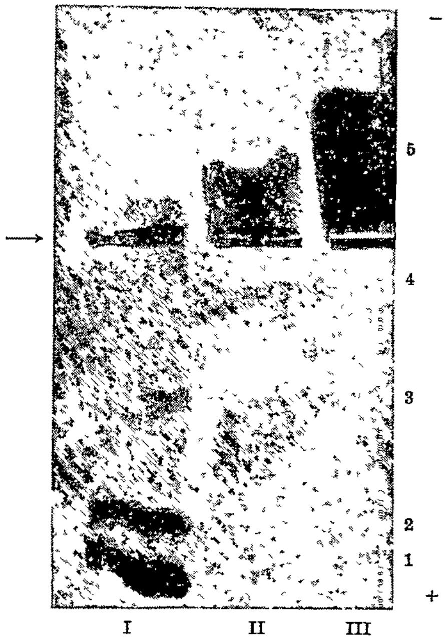

Fig 3 Separation of LDH isozymes in starch gel I, Homogenate of rat heart, II, nuclear extract from rat liver, III, cytoplasmic soluble fraction from rat liver, 1–5, LDH isozymes The arrow indicates the starting line

cytoplasm starts at a higher pyruvate concentration (1×10^{-2} molar) than in the nuclei (1×10^{-3} molar). This is indirect evidence that there is more LDH-5 in the cytoplasm than in the nucleus

Direct evidence of this difference was obtained by subjecting the solutions to electrophoresis in starch gel As the LDH zymograms show (Fig 3), both the nucleus and cytoplasm of the rat liver cells are represented by isozymes 3, 4 and 5, with distinct, though quantitative, differences between the nucleus and cytoplasm These differences mostly concern LDH-5 which can be found in larger amounts in the cytoplasm than in the nucleus. A quantitative evaluation of these differences was obtained by spectrophotometric measurements of LDH activities in corresponding sites of the electropherogram after freezing and thawing It has been established that the activity of LDH-5 expressed in units of the enzymes is 4 to 5 times greater in the cytoplasm than in the nucleus As for LDH-3 and 4, there are only traces of them in the cytoplasm, while their activity in the nucleus is about 50 per cent of the activity of LDH-5.

It should be pointed out that the differences in the LDH activity of the nucleus and cytoplasm can only be shown by using electrophoresis in starch gel When electrophoresis was carried out using paper the LDH activity in the nucleus and cytoplasm of rat liver cells had only one corresponding band[12].

Thus LDH of the nucleus and cytoplasm of rat liver cells show different isozyme contents This agrees with the suggestion that glycolytic enzymes in the cell are bound to structures and are not capable of moving freely from one part of the cell to another[13–15] Recently it has been suggested that LDH is synthesized in both the nucleus and the cytoplasm[16] These data may explain differences in the isozyme content of LDH of the cell There may be evidence for the isozymes playing a physiological part in the regulatory processes of the cell The LDH isozymes that show different kinetic properties may regulate the ratio of $NADH_2$ to NAD in the transformation of pyruvate into lactate which is important for controlling many reaction rates in the cell[6] Furthermore, the suggestion that LDH isozymes show allosteric regulatory ability offers a method for regulating their relative contribution to the total LDH activity According to Kaplan[18], whose hypothesis is based on the fact that LDH-1 is inhibited by pyruvate concentrations to which LDH-5 is resistant, LDH-1 must prevail in tissues with aerobic metabolism, while LDH-5 prevails in tissues with anaerobic metabolism In this connexion, an increased amount of LDH in the cytoplasm compared with the nucleus seems to indicate that the soluble fraction of the cytoplasm plays a principal part in the anaerobic method of energy supply in the cell

Urokinase Inhibitor in Human Placenta

Fibrinolytic activity in the blood markedly decreases in the later months of pregnancy and in labour, but rapidly returns to normal after delivery[1–3] Brakman and Astrup[4] observed a significant increase in the selective inhibition of fibrinolysis induced by urokinase in plasma and serum of pregnant women, and their findings suggested that an inhibitory mechanism was involved in depressing fibrinolysis during pregnancy The same characteristics of fibrinolytic inhibition in saline extract of human placenta have been reported by one of us[5], that is placental extract inhibited only urokinase but not streptokinase or glycerol-activated plasmin Because the placental extract contained blood components, however, it was uncertain whether the inhibition was derived from pregnancy blood or from placenta itself

The purpose of this communication is to report that the selective inhibition of placental extract by urokinase is chiefly derived from the placenta itself Two hundred human placentae, frozen immediately after parturition, were minced, mixed with 200 l of 0 9 per cent saline and stirred for 30 min Placental extract was obtained as the supernatant after centrifugation The protein concentration was about 2 0 per cent, of which haemoglobin constituted 50 to 70 per cent The concentration of the other proteins (chiefly plasma proteins) was therefore 0 6–1 0 per cent

Usually 1,200 ml of saline extract was obtained from one placenta Samples of blood were obtained from women in the third trimester of pregnancy and allowed to clot by storing in a refrigerator overnight Serum was then separated by centrifugation The normal serum used here was prepared from citrated, pooled plasma from 100 donors by adding 2 NIH units/ml of human thrombin and removing any clots after retraction

Inhibitory activity against urokinase was determined on normal fibrin plates, which were prepared by the method of Astrup and Mullertz[6], as modified by Alkjaersig, Fletcher and Sherry[7] Human fibrinogen and human thrombin were used instead of bovine products as in the original papers

Urokinase solution was prepared by dissolving a urokinase preparation (Green Cross Corp , Osaka) in 0 9 per cent saline to give a concentration of 30 Ploug units (ref 8) of urokinase/ml and this was mixed with an equal volume of saline The mixture was then diluted two-fold with saline The former mixture was taken as 100 per cent activity and the latter as the control at 50 per cent activity

Samples were diluted with saline in two-fold dilution series and each 0 5 ml of the diluted samples was mixed with 0 5 ml of the urokinase solution A sample of each mixture (0 02 ml) was put on a fibrin plate in duplicate After incubation at 37° C for 20 h, the lysis areas were measured and plotted against sample concentrations on log-log paper

A sample concentration giving 50 per cent inhibition was determined from the lysis area equivalent to the 50 per cent activity described One inhibitory unit was defined as the activity necessary to inhibit 1 Ploug unit of urokinase, and so the number of inhibitory units/ml in an original sample was calculated by multiplying the dilution factor of the sample giving 50 per cent inhibition by 15

Inhibitory activity against trypsin was determined on heated fibrin plates[9] as for urokinase Trypsin solution was prepared by dissolving twice crystallized trypsin to give 23 4 γ/ml of 0 025 molar calcium chloride solution One inhibitory unit was defined as the activity which inhibited 1γ of trypsin and therefore the number of inhibitory units/ml in an original sample was calculated by multiplying the dilution factor of the sample giving 50 per cent inhibition by 11 7

Results are shown in Table 1 Pregnancy sera showed stronger inhibition of both urokinase and trypsin than did normal sera The increase of urokinase inhibitor[4] and trypsin inhibitor[10] in pregnancy blood was confirmed The values for inhibitory activity against trypsin in both pregnancy serum and normal serum were greater in our results than in those of Faarvang and Lauritsen[10], but the reason for the difference was not clear

Compared with pregnancy sera, placental extracts showed a much stronger inhibition of urokinase and much weaker inhibition of trypsin The concentration of plasma proteins in placental extracts was calculated to be about one tenth of the sera and the average ratio of trypsin inhibition by placental extracts to trypsin inhibition by pregnancy sera corresponded to this value, so that the trypsin inhibitor in placental extract is probably derived from pregnancy blood alone On the other hand, there was on average 8 4 times as much urokinase inhibitor in placental extract as in pregnancy serum The selective urokinase inhibitor, which has been found in placental extract[5], must therefore be chiefly derived from the placenta itself

Table 1. INHIBITORY UNITS/ML OF PLACENTAL EXTRACT, PREGNANCY SERUM AND NORMAL SERUM

	Against urokinase	Against trypsin
Placental extract	1,420	378
	1,970	337
	1,810	359
(Average)	(1,730)	(358)
Pregnancy serum	109	3,630
	180	2,755
	297	4,970
	218	4,310
	237	3,000
	220	4,670
	175	3 355
(Average)	(205)	(3,813)
Normal serum	48	1,855
	30	2,350
	30	1,470
	32	1,585
(Average)	(35)	(1,815)

As much as about 2×10^6 units of urokinase inhibitor can be extracted from a placenta This is comparable with 10 l. of pregnancy serum, and this fact suggests a reason for the abrupt return to normal of the time of euglobulin lysis after placental separation[3]

Evidence for a Genetic Relationship between Avidins and Lysozymes

PROTEINS which bind biotin do not seem to be widely distributed in nature, possibly because their function seems to be restricted to that of a somewhat inefficient antibacterial agent Until recently, avidin had been detected only in the egg-white of birds and in the homologous egg jelly of frogs[1] In 1963 an avidin-like protein was discovered as part of an antibiotic system in culture filtrates of several species of *Streptomyces*[2]. This protein, called streptavidin, was purified, crystallized and characterized by Chaiet and Wolf[3], who found that it resembled egg-white avidin both in possessing four biotin binding sites (one/15,000*g*) with great affinity for biotin and in some aspects of its amino-acid composition (high tryptophan and threonine, low methionine, proline and histidine) Many of the characteristics of the biotin binding mechanism were also similar There was a red-shift of the tryptophan absorption band accompanying the binding of biotin, and at the same time the biotin protected four tryptophan residues in each sub-unit against oxidation by *N*-bromosuccinimide (ref 4 and my unpublished work) Like avidin, streptavidin also bound the dye 4-hydroxyazobenzene-2′-carboxylic acid giving a new absorption band at 500 mμ which disappeared when the dye was displaced by biotin[5] Some of the physico-chemical characteristics of these two proteins and of hen egg-white lysozyme are summarized in Table 1

Table 1 PHYSICO-CHEMICAL CHARACTERISTICS OF AVIDINS AND LYSOZYME

	Avidin	Streptavidin	Lysozyme

* Results published here for the first time using methods described in refs 4 and 5

Although the probable biological roles of avidin and lysozyme are similar, the biochemical bases of their performance are quite unrelated While lysozyme acts as a muramidase on many types of bacterial cell wall, avidin holds biotin in a firm non-covalent grasp and exerts no

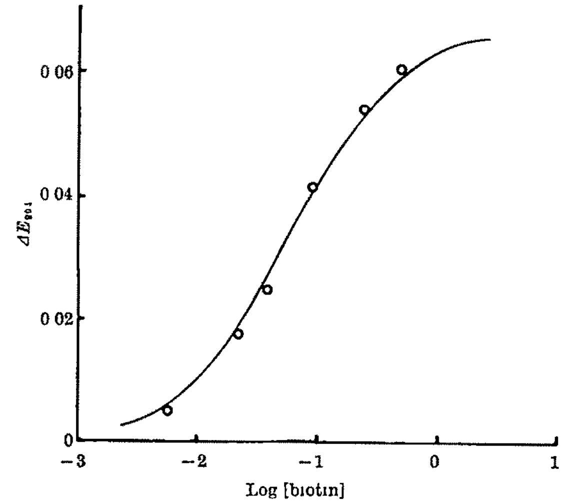

Fig 1 Effect of increasing biotin concentration on the spectrum of lysozyme A series of difference spectra were run of lysozyme ($E_{280} = 2\ 2$) + biotin against lysozyme, in cuvettes of path length 0 1, 0 5, 1 0 and 4 0 cm The solvent was 0 05 molar sodium acetate buffer, *p*H 6 0 at 25° C The difference spectrum showed a double maximum (286, 294 mμ) typical of a red-shifted tryptophan spectrum Both the spectrum and its concentration dependence resembled that given by *N*-acetyl glucosamine with lysozyme[9,16] The change in absorbance at 294 mμ was corrected for the small contribution from free biotin The continuous curve was calculated from the law of mass action for binding of a single biotin molecule with $K = 0\ 04$ molar

apparent catalytic action Moreover, lysozyme has no sub-units, while avidin has four[8] The only functional similarities are the red-shifts of the tryptophan spectra, observed when both proteins combine with their respective substrates or analogues, and the loss of activity when one or two of the tryptophan residues are oxidized by *N*-bromo-succinimide[4,9]

It was therefore with some surprise that I noted a few years ago a marked resemblance in the amino-acid compositions of these two proteins[10,14] Unsuccessful attempts were made to show inhibition by biotin of the action of lysozyme on the cell walls of *B subtilis* No effects were detectable, even with biotin concentrations of 0 1 molar Recently, however, the formation of a biotin-lysozyme complex has been detected in the absence of substrate, using the red-shift of the tryptophan spectrum to measure complex formation From the effect of biotin concentration on the difference spectrum (Fig 1) the dissociation constant was found to be 0 04 molar It is difficult to evaluate the significance of such a weak interaction, although it is no weaker than that between lysozyme and *N*-acetyl glucosamine[15,16] It was not merely caused by hydrogen bonding of the ureido ring of biotin, for hydrolysis of this ring to give a diamine had little effect on the binding Although one cannot give much weight to this evidence in isolation, it is of some significance in the context of the other similarities discussed here The reciprocal system of avidin with *N*-acetyl glucosamine (0 15 molar) showed no spectral shifts

It is now interesting to ask whether there is any comparable relation between streptavidin and lysozymes of *Streptomyces* Fortunately, Ward and Perkins have recently purified two similar lysozymes from *S griseus*, which they showed to be muramidases[17], and have determined their amino-acid composition[18] The analysis for the better characterized lysozyme 2 is shown in Fig 2 It provides further support for the avidin-lysozyme relationship

Before discussing these amino-acid analyses in more detail, I would like to introduce one further member of the lysozyme family This is the protein α-lactalbumin, whose amino-acid sequence was recently determined[19], after the observation of a resemblance between its molecular weight and composition and that of lysozyme[20] After allowing for a few small deletions it was found that forty out of the 123 amino-acid residues were identically placed and a further twenty-seven showed conservative changes The composition of bovine α-lactalbumin is therefore included in Fig 2 for comparative purposes

In spite of the strikingly homologous sequence, the composition of lactalbumin is no closer to that of lysozyme than is that of avidin Each avidin resembles its corresponding lysozyme in its content of about ten of the eighteen amino-acids. The totals of basic amino-acids and of acidic amino-acids are also similar The resemblance in composition is closer than that between trypsinogen and chymotrypsinogen[21] or haemoglobin and myoglobin[22], where the genetic relationships are firmly based on sequence identities By analogy with these established cases, it is likely that the similarities of composition imply that avidins and lysozymes have an appreciable proportion of their sequences in common and that they have originated by differentiation from a common ancestral protein Although argument from composition is not the best way of establishing relationship between proteins, it is here particularly convincing because of the unusual composition and low molecular weight of lysozyme

There are also some considerable differences in composition between avidins and lysozymes, as would be expected for such functionally different proteins The most interesting of these differences are common to both pairs of proteins (from hen egg-white and from *Streptomyces*) The avidins have a much higher content of threonine—it is

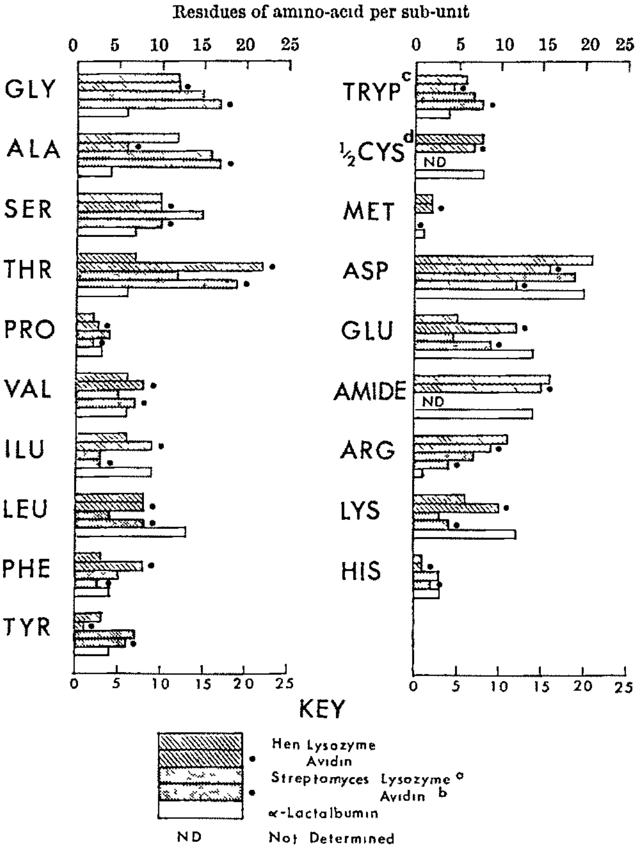

Fig 2 *a*, The analytic results for the *Streptomyces* proteins lack figures for cystine and amide groups The numbers of residues given were calculated on the basis of a molecular weight of 14,000 for the lysozyme and 15,000 for streptavidin All figures are given to the nearest residue or, if there are fewer than ten residues, the nearest half residue No corrections were applied for losses of serine and threonine during the 24 h hydrolysis *b*, The streptavidin analysis was carried out on a sample hydrolysed for 24 h in 6 molar HCl at 110° C *in vacuo* The results agreed well with those of Chaiet and Wolf[3], except that they found only traces of arginine and made no mention of proline They also found six residues of isoleucine and some "α-aminobutyric acid" *c*, Spectrophotometric determination[14] *d*, There are no free sulphydryl groups on avidin, and so there are probably four cystines per sub-unit, or perhaps two sub-units with three and two with four cystines higher than that of any other protein for which figures are available—and they contain more glutamic and less aspartic acid than do the lysozymes In both cases, the avidin has a higher molecular weight, accounted for by an extra ten to twenty amino-acid residues, about half of which appear to be threonine There are also individual differences, such as the presence of mannose and *N*-acetyl glucosamine[14] and the low content of alanine in avidin

One may next enquire whether the similarities of composition and probably of sequence give rise to any common pattern of tertiary structure Both the egg-white proteins (and lactalbumin) have four disulphide bonds and are stable over a wide range of *p*H and temperature The *Streptomyces* proteins are also rather stable, although there is no information concerning their disulphide bonds Both avidin and streptavidin retain their activity in 3–4 molar guanidinium chloride[23] The ORD and CD spectra (Table 1) of both egg-white proteins show positive Cotton effects at 280 mμ arising from the absorption of the aromatic amino-acids There is, however, no evidence from the shorter wavelength region for any α-helix in avidin, while lysozyme contains about 20–30 per cent of its residues in this conformation It is impossible to say how big a difference in sequence is necessary to produce this transformation of tertiary structure It need not necessarily be large, for a few strategically placed charged residues could disrupt a considerable length of α-helix Admittedly, the haemoglobin-myoglobin family has maintained an almost invariant tertiary structure in the face of considerable variation in sequence It should be remembered, however, that these proteins have been selected for a common haem and oxygen binding function, whereas avidin and lysozyme have been selected with different ends in view.

It is implicit in current ideas about the origin of life that the enormous diversity of enzymes and proteins now existing have descended from a much more restricted number of parent proteins The common ancestry of many functionally unrelated proteins should eventually become clear when more amino-acid sequences are known So far, sequence work has been centred on functionally related proteins[24], the cytochromes, haemoglobins and myoglobins, and on the active centres of proteases[25] and dehydrogenases[24] The first clear example of two more distantly related proteins with a common basic sequence is that of lysozyme and α-lactalbumin mentioned above It now seems that we can add avidin and streptavidin to this family, whose further relatives may be recognizable by their somewhat unusual amino-acid composition

So far lysozyme and avidin have been compared within a species If the two hen egg-white proteins are compared with their homologues from *Streptomyces* some further interesting correlations can be made It will be seen that glycine. alanine, isoleucine, tyrosine, methionine, arginine and lysine all change in parallel on going from one species to the other Similar parallels have been observed when the haemoglobins and myoglobins of primates were compared with those of fishes[26] If these changes are significant, they could be explained, either by postulating a primitive gene, say for lysozyme, which has been duplicated on at least two separate occasions, followed by parallel differentiation of the duplicates to give biotin binding proteins, or by postulating a single early duplication followed by parallel changes in both lysozyme and avidin genes during the evolution of birds from the precursors of actinomycetes Both interpretations seem to require improbable coincidences and it is profitless to argue the balance of improbabilities until more information is available If the avidins diverged from the lysozymes after a single early duplication, the avidin structural gene and possibly avidin itself would be expected to be present in many species more primitive than birds and amphibia If both avidin and lysozyme perform an antibacterial function, it is possible that both proteins will be produced together in situations where the organism requires such protection A search conducted with this in mind might show avidin to be more widespread than has hitherto seemed likely

It is interesting to recall that in 1942 Meyer[27] proposed that avidin and lysozyme were related, basing his suggestion largely on the difficulty of separating the two proteins from each other Further experiments failed to substantiate this claim, but it now seems that Meyer's original suggestion may not have been so wide of the mark as it seemed to be at that time It is to be hoped that the present proposals are more firmly based and that fingerprinting and sequence studies will eventually confirm them

I thank Dr F J Wolf for streptavidin, Dr H R Perkins for allowing me to use his analytical results in advance of publication, Dr S Jacobs for the amino-acid analysis of streptavidin and Mr E J Toms for technical assistance

Electrophoretic Study of Glutathione Reductase in Human Erythrocytes and Leucocytes

THE question of whether the activities of NADPH—or NADH—glutathione reductase are caused by a single enzyme or by two different enzymes has never been satisfactorily resolved[1–4] We have devised a new method for detecting glutathione reductase (GSSGR) activity after starch gel electrophoresis The study of subjects with an electrophoretically fast mutant glutathione reductase has enabled us to present findings which strongly favour the suggestion that glutathione reductase activities with respect to both pyridine nucleotide coenzymes reside in the same molecule Some observations have also been made in glutathione reductase deficient and NADH-diaphorase (NADH methaemoglobin oxido-reductase) deficient subjects

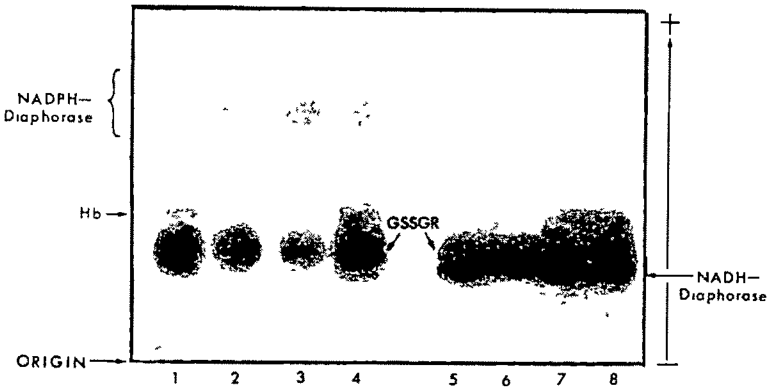

Fig 1 Gel stained for NADPH-glutathione reductase (1–4) and NADH-glutathione reductase (5–8) 1 and 5, Haemolysate from a normal subject No 1, 2 and 6, haemolysate from normal subject No 2, 3 and 7, haemolysate from patient No 1 with partial deficiency in glutathione reductase (activity, 30 per cent of normal), 4 and 8, haemolysate from patient No 2 with partial deficiency in glutathione reductase (activity adjusted to normal) 1–4, With GSSG and NADPH as substrates (see text), 5–8, with GSSG and NADH as substrates (see text) Hb designates the red haemoglobin band

Glutathione reductase catalyses the reaction

$$GSSG + NADPH \text{ (or NADH)} + H^+ \rightarrow 2 \; GSH + NADP \text{ (or NAD)}$$

Our method for detecting glutathione reductase activity is based on the fact that reduced glutathione (GSH), a product of the reaction, rapidly reduces 2,6-dichlorophenol indophenol (DCIP) The reduced DCIP reacts with a tetrazolium salt (3 (4,5-dimethylthiazolyl-2)-2,5-diphenyl tetrazolium) (MTT)[5]—a reaction which is not catalysed by enzymes—and the resulting dark blue formazan precipitate permits the localization of glutathione reductase activity on the gel This method differs from the only other technique[6], not only in a more rapid staining of the gel, but in the capacity to clearly detect the NADH activity as well as the NADPH activity in a positive stain

Haemolysates were prepared by adding two volumes of cold distilled water to the washed red cells and freezing and thawing three times The stroma was discarded after centrifugation at 31,000*g* for 30 min Leucolysates were prepared by adding one volume of cold distilled water to one volume of packed leucocytes which had been substantially freed of erythrocytes by osmotic shock lysis The suspension was frozen and thawed three times and centrifuged at 1,600*g* for 15 min Horizontal starch gel electrophoresis was carried out with an average gradient of 20 to 25 V/cm for 4 h at 4° C A 0·1 molar *tris*-hydrochloric acid buffer, *p*H 9 6 (4° C), containing 4 5 mmolar ethylenediamine tetra-acetic acid (EDTA) was used for the electrode compartments, a dilution 1 10 of this buffer was used for the starch gel The sliced gel was stained in the dark for 2 h, at room temperature, with a freshly prepared developing mixture of 3 4 mmolar oxidized glutathione (GSSG), 1 3 mmolar NADPH, 1 2 mmolar MTT, and 0 04 mmolar DCIP in a 0 25 molar *tris*-hydrochloric acid buffer *p*H 8·4 To detect NADH-glutathione reductase activity, 1 3 mmolar NADH was substituted for NADPH

This reagent mixture detects the activity of diaphorase as well as glutathione reductase, because the diaphorase will transfer an electron directly from the reduced pyridine nucleotide to DCIP, and thus reduce MTT[5] One side of the gel was therefore always stained with a reaction mixture from which GSSG had been omitted, in order to identify clearly the position of the diaphorase bands

Using NADPH, a distinct pattern of glutathione reductase activity was obtained, consisting of a single band located between Hb A and Hb A$_2$ in the haemolysates In the leucolysates a band with an identical mobility was observed There was no interference from the NADPH-diaphorase because this enzyme migrates far ahead of haemoglobin[5]

Accurate localization of erythrocyte glutathione reductase activity using NADH as an electron donor poses technical problems because the NADH-diaphorase, which is visualized at the same time, has almost the same mobility, being only slightly slower Because of this, and because of the relatively low activity of the NADH-glutathione reductase, clear cut patterns are not seen in haemolysates (Fig 1). In leucolysates, however, there is no such interference because leucocyte NADH-diaphorase is usually not released into the supernatant without special treatment (our unpublished data) The NADH-glutathione reductase can thus be seen clearly in leucocyte extracts (Fig 2). Its mobility was found to be identical to the NADPH-glutathione reductase of erythrocytes and leucocytes

An electrophoretically fast variant of NADPH-glutathione reductase, probably identical to the type described recently by Long[6], has been found among normal Negroes Some subjects, apparently homozygotes, have a single fast band, others, apparently heterozygotes, have a wide band representing the juxtaposition of the normal and the variant band This was observed in both erythrocytes and leucocytes, and this finding is consistent with the assumption that the enzyme is under the same genetic control in both cell types In a subject homozygous for the fast variant of glutathione reductase, the fast band observed with NADPH was also obtained with NADH at the same position This was seen most clearly in leucolysates (Fig 2), but was also evident in haemolysates

Haemolysates from two subjects with partial glutathione deficiency have been studied Their glutathione reductase had a mobility identical to the common normal glutathione reductase, both with NADPH and NADH

Subjects with congenital methaemoglobinaemia with erythrocyte NADH-diaphorase deficiency have been found to show a decrease in glutathione reductase activity of about 20 per cent[7] The possibility that these two enzymes share a common sub-unit seemed to warrant consideration Accordingly we have studied three subjects homozygous for NADH-diaphorase deficiency, one of whom had an electrophoretic abnormality of the enzyme (the California variant)[5] Although they had a moderate decrease of erythrocyte glutathione reductase activity, no electrophoretic abnormality was found Furthermore, in haemolysates from these subjects, a well defined band of NADH-glutathione reductase activity could be obtained, without interference from the completely or almost completely missing NADH-diaphorase band The position

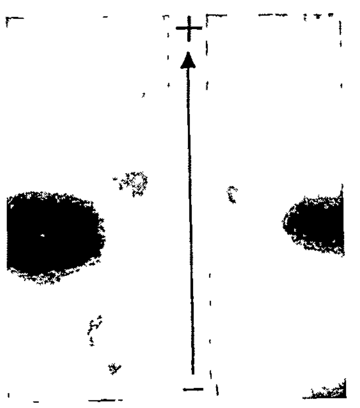

Fig 2 1 and 4, Leucolysate from a normal control, 2 and 3, leucolysate from a homozygous subject for the fast variant of glutathione reductase Gel stained for NADPH- (1–2) and NADH-glutathione reductase (3–4) of NADH-glutathione reductase band confirmed the identical mobility of NADH- and NADPH-glutathione reductase band in erythrocytes

We find that glutathione reductase activity of normal leucolysates and haemolysates moves with identical electrophoretic mobility regardless of whether NADH or NADPH is employed as hydrogen donor This, and the further finding that identical mobilities are also observed when haemolysates and leucolysates are examined from subjects with an electrophoretically detectable mutant enzyme, strongly supports the idea that activities with the two hydrogen donors are the properties of the same enzyme molecule The less likely possibility, however, that there are two different enzymes sharing a common sub-unit which is affected by the electrophoretic mutation cannot be altogether eliminated by the studies reported The glutathione reductase from two subjects with quantitative diminution of glutathione reductase activity has been found to be electrophoretically normal The technique which we have reported for identifying the position of glutathione reductase in starch gel should make it possible to study other families already reported[4,8-10], in order to determine whether further electrophoretic polymorphisms involving the enzyme exist

This work was made possible by a supporting fund established in the name of the Barry T Leithead Research Fellowship, and was supported, in part, by a US Public Health Service grant from the National Heart Institute, National Institutes of Health

Electrophoresis of Ferritins

ELECTROPHORETIC studies of ferritins—iron containing proteins—from horse, man and HeLa cells have already been recorded[1,2] This communication describes the electrophoretic patterns of a plant ferritin known as phytoferritin[3] and of ferritins from pig, ox and guinea-pig, compared with human and horse ferritin

The ferritins other than guinea-pig and phytoferritin were extracted by the method of Granick which, briefly, consists of homogenizing the tissue (liver or spleen) in distilled water and heating to 80° C, after which the supernatant is half saturated with ammonium sulphate, and the precipitate is dissolved in distilled water The ferritin present in the solution is crystallized with cadmium sulphate, and finally purified by recrystallization When processed in this way bovine and porcine ferritins fail to crystallize

To provide an adequate ferritin yield old stock guinea-pigs were given three intraperitoneal injections of 2 ml of 1 per cent iron ammonium citrate every other day and the animals were killed on the day after the last injection Extraction of the liver and spleen was carried out using Friedberg's modification of Granick's method[4]

Phytoferritin was extracted[3] from the primary and secondary leaves of the French bean, *Phaseolus vulgaris*, grown in an iron enriched soil

Human ferritin was extracted from the liver and spleen of a patient with myeloid metaplasia Horse ferritin, the easiest of all ferritins to prepare, was extracted from the spleen of an old animal

The pattern of bands shown by the ferritins was compared in polyacrylamide gel electrophoresis using 5 per cent acrylamide gel, *p*H 7 2, run for 75 min at 5 m amp/tube The six ferritins examined differed in their mobility (Fig 1), the slowest moving being bovine, with porcine, human, horse, guinea-pig and the phytoferritin forming a series of increasing speed of mobility

Polyacrylamide gel acts like a molecular sieve, and so it is reasonable to suppose that the rate of movement of the ferritin is a function of their size Unfortunately electron microscopy, using the phosphotungstic acid negative contrast technique, and ultracentrifuge studies failed to demonstrate any appreciable difference in size between the human and horse ferritins, although in the polyacrylamide gel electrophoresis the former moved more slowly

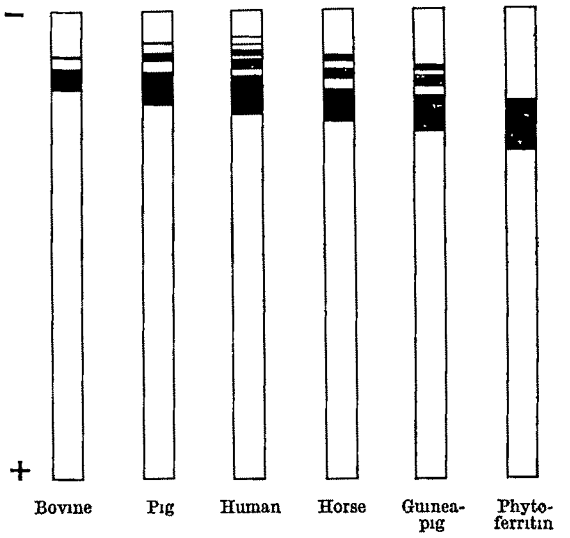

Fig 1 Patterns shown by ferritins from various species when examined in standard conditions by polyacrylamide disc electrophoresis

The number of bands formed by the ferritins in standard conditions of 500 μg/tube varied, human ferritin formed five bands, guinea-pig, horse and porcine three bands, bovine two and phytoferritin remained as one broad band

Hyde[3] reported that the electron microscopic, centrifugal and spectrophotometric properties of phytoferritin were very similar to those of animal ferritins In the samples we examined, phytoferritin did not show band formation This may be a consequence of the low concentration of the material in the plant, or in the extract, for in other ferritins the minor bands are not demonstrable when the concentration of ferritin is very low.

It is believed that at high concentrations the molecules of ferritin aggregate to form polymers When each of the monomer, dimer and trimer bands of horse ferritin were eluted and examined with the electron microscope they showed a proponderance of single, double and treble molecules respectively[5] We have been able to demonstrate similar aggregates in samples eluted from the bands of human ferritin prepared by electrophoresis in polyacrylamide gels

IMMUNOLOGY

Absence of β-Globin Synthesis and Excess of α-Globin Synthesis in Homozygous β-Thalassaemic Subjects from the Ferrara Region

β-Thalassaemia is a genetically determined anaemia of man, characterized by a decrease in production[1-6] or the absence[7] of β-globin, and by an excess of α-globin synthesis[4,6-8], which results in the $\alpha/(\beta+\gamma+\delta)$ globin synthesis ratio largely exceeding the normal value of 1 0

The high frequency of occurrence of the β-thalassaemic gene in the area of Ferrara, Northern Italy[9], has provided us with the opportunity to examine a relatively large number of homozygous and heterozygous β-thalassaemic subjects The investigations were based on the following determinations (*a*) globin chain synthesis in peripheral blood and bone marrow erythroid cells, and (*b*) characterization of the β-thalassaemic haemoglobin types by starch gel electrophoresis and by column chromatography on 'Amberlite *IRC* 50'

A typical separation of labelled thalassaemic globin chains is shown in Fig 1 This shows the absence of β-globin and the excess of α-globin synthesis in reticulocytes from homozygous β-thalassaemic patients, confirming our previous findings[7] Erythroid cells from bone marrow have an identical chromatographic pattern, except for the amino-acid incorporation, which is greater

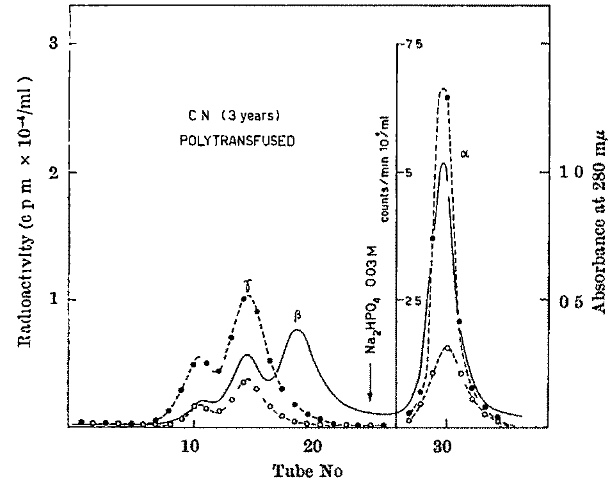

Fig 1 Column chromatography on CM-cellulose of the labelled globin chains from a homozygous β-thalassaemic subject The erythroid cells from the peripheral blood and from the bone marrow of the subject were incubated with ^{3}H amino-acids[7,10] The chromatographic separation was performed according to the procedure of Clegg *et al*[11] Each tube corresponds to 2 5 ml ———, *OD* pattern, ○ - - - ○, peripheral blood radioactivity, ● - - - ●, bone marrow radioactivity

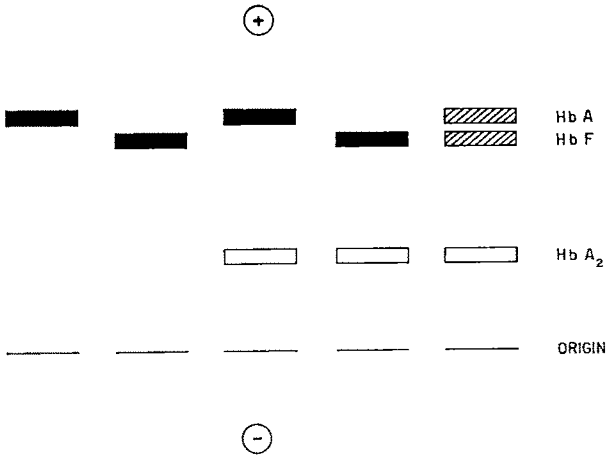

Fig 2 Starch gel electrophoresis at *p*H 8 6 (tris-EDTA-borate) of the haemoglobin types present in the various subjects examined The diagram refers, from left to right, to purified haemoglobin A, purified haemoglobin F, haemoglobins from the peripheral blood and from the bone marrow of homozygous β-thalassaemic subjects who had never been transfused, haemoglobins from the peripheral blood and from the bone marrow of poly-transfused homozygous β-thalassaemic patients

The excess of α-globin synthesis, as calculated from the chromatographic analyses, on *CM*-cellulose, of the β-thalassaemic subjects examined, is shown by Table 1 The ratio of α-globin synthesis to counterpart globin synthesis, observed in reticulocytes, is comparable with that in erythroid bone marrow cells, this ratio, equal to 3 0 in the homozygous state, becomes 1 7 in the heterozygous state The ratio of the control subjects is 1 0 (Table 2)

Starch gel electrophoresis of the haemoglobin types of the subjects examined is shown in Fig 2 The patterns reveal the absence of the band corresponding to haemoglobin A in the subjects who have never been transfused The presence of the haemoglobin A band in the polytransfused patients is derived from the transfused normal haemoglobin In fact (see Fig 3) the intensity of the adult haemoglobin band is related to the time between transfusion and chromatographic analysis

	Average	1 0

A typical chromatographic pattern on 'Amberlite *IRC* 50' of the haemoglobins from β-thalassaemic reticulocytes and from erythroid cells of the bone marrow, after amino-acid incorporation, is shown in Fig. 4 The elution profile reveals the presence of three proteins corresponding to haemoglobin F, haemoglobin A and haemoglobin A_2 The first and the third peaks are radioactive, while the second contains no detectable radioactivity This pattern is consistent with the findings obtained with the other techniques and confirms the absence of β-globin synthesis in homozygous β-thalassaemia. The sensitivity of this technique in detecting the various haemoglobin fractions has been reported to be 0 1 per cent[13]

These findings provide further evidence that the gene for β-globin, in homozygous β-thalassaemic subjects from the Ferrara region, is not expressed This result is substantiated by the many cases so far examined (forty-two) and by the evidence provided by several techniques (Of the forty-two patients so far examined, four were originally from other areas of thalassaemia in Italy. In four cases, not described in this report, β-chain synthesis was suggested by the chromatographic pattern of the globin, further studies are in progress to characterize these subjects) The absence of β-globin in our population, compared with the decreased synthesis observed in other areas, suggests that Cooley's disease is caused by a heterogeneous group of mutation of the β-gene, leading to the synthesis of different amounts of β-globin in different thalassaemic populations

The identical behaviour of reticulocytes and bone marrow erythroid cells excludes a selective retention in the bone marrow of cells which synthesize β-globin, and the presence of functional messenger RNA for β-globin during the different stages of maturation of red blood cells

The absence of β-globin is known to be associated with an excess of α-globin synthesis· this can be interpreted as a consequence of the defect in β-globin synthesis, because it is higher in the homozygous than in the heterozygous state

The free α-chain does not tend to assume a stable tetrameric form[14,15] and, as reported elsewhere[10], is rapidly removed from the cytoplasm, becoming associated with the stromal material This may be the reason why only small amounts, if any, of free α-chain are detectable in the β-thalassaemic haemolysates by either chromatographic or electrophoretic techniques[16,17], while β_4-tetramers (HbH) or γ_4-tetramers (Hb Bart), because of their higher stability, are detectable in α-thalassaemic haemolysates

This work was supported by grants from the Italian Consiglio Nazionale delle Ricerche. Impresa di Enzimologia, the US National Institutes of Health, NATO, and the Cooley's Anemia Blood and Research Foundation for Children, Inc , USA

Effect of F(ab')₂ from Rabbit Anti-mouse Lymphocyte IgG on the Graft versus Host Reaction in F_1 Hybrid Mice

HETEROLOGOUS antisera raised against lymphoid cells (ALS) have been found to suppress a large variety of immune responses (see review by James[1]) In particular, lymphoid cells from mice which have been treated with

ALS exhibit a diminished ability to produce graft versus host (GVH) reactions[2-5]. Such responses result from immunological interaction between lymphoid graft and the histocompatibility antigens of the host. One such reaction occurs when parental spleen cells are injected into adult F_1 hybrid mice, and its occurrence and severity can be assayed by measurement of the resulting increase in size of spleen and liver[6]. As anti-lymphocytic antibody fragments seem incapable of suppressing humoral antibody formation[7-10] and inhibiting allograft rejection[11], we have investigated the effect of such preparations on the following GVH system.

We have compared the ability of spleen cells from *C57Bl* mice treated with intact IgG and fragments (antibody and normal) to produce a GVH-reaction on subsequent injection into normal $(C57Bl \times CBA)F_1$ hybrid recipients. The mice used were derived from inbred strains maintained in this department; the *C57Bl* donors were males and females weighing 25–30 g and the recipient F_1 hybrids were males between 30 and 35 g.

ALS was raised by intravenous injection of New Zealand white rabbits with about 10^9 *CBA* mouse thymus cells on each of three occasions during a 4 week period. The rabbits were bled 1 week after the last injection. The ALS obtained was inactivated (56° C for 30 min) and absorbed with mouse erythrocytes to remove agglutinins.

Small amounts of this antiserum prolonged the survival (three times) of A strain skin grafts on *CBA* male mice and produced a marked lymphopenia in *C57Bl* mice. The normal rabbit serum (NRS) IgG and rabbit anti-mouse lymphocyte IgG preparations used in these studies were prepared by batch chromatography[12] on Whatman *DE*52 ion exchange cellulose (degree of substitution = 1.0 m equiv./g). Immunoelectrophoresis using a sheep anti-whole rabbit serum indicated that the products contained only trace amounts of contaminating proteins. The non-cytotoxic $F(ab')_2$ portion of the antibody molecule (which contains both antibody combining sites) was obtained by pepsin digestion[13] at 37° C for 24 h in *p*H 4.0, 0.1 molar acetate buffer. For each 100 mg of protein 2 mg of enzyme was used. Degradation of the IgG to the $F(ab')_2$ product was shown to be complete by immunodiffusion and cytotoxic analyses. The products were concentrated to 1 g per cent by ultrafiltration and dialysed against 0.15 molar sodium chloride before use.

C57Bl donor animals were given a total of 1 ml of the appropriate 1 g per cent preparation intraperitoneally in doses of 0.25 ml on days 4, 3, 2 and 1 prior to cell transfer.

Spleen cell suspensions were prepared from the pooled spleens of four or five treated animals by gently breaking them up in a ground glass homogenizer containing balanced salt solution plus 0.1 per cent normal mouse serum. The suspensions were passed through a fine meshed stainless steel sieve, allowed to stand for 10 min at 4° C, then the cells in the supernatant were washed twice and re-suspended to give a concentration of about 200×10^6/ml. The viability of the cells was assessed by their ability to exclude 0.05 per cent trypan blue, and was never less than 86 per cent. The volume necessary to give a dose of 100×10^6 viable cells was calculated, and this volume of suspension was injected into the tail vein of the appropriate animal.

The $(C57Bl \times CBA)F_1$ animals were arranged in six groups, as shown in Table 1. Nine days after cell transfer the animals were weighed, killed by cervical dislocation, and the weights of their spleens and livers determined.

As Table 1 shows, ALS IgG alone inhibited the production of splenomegaly and hepatomegaly while ALS $F(ab')_2$ and the normal IgG preparations were ineffective. This result is in agreement with other findings that anti-lymphocytic fragments seem incapable of suppressing humoral antibody formation[7-10] or inhibiting homograft rejection[11], and suggest that the immunosuppressive properties of ALS are dependent on the possession of an intact Fc (complement binding) portion. It is possible, however, that other properties associated with this region of the molecule are involved (that is, membrane attachment, placental transfer, immunogenicity).

Table 1. MEAN RELATIVE SPLEEN AND LIVER WEIGHTS OF $(C57Bl \times CBA)F_1$ HYBRID MICE, 9 DAYS AFTER INTRAVENOUS INJECTION OF 100×10^6 SPLEEN CELLS FROM *C57Bl* MICE OR SALINE

Group	No.	Relative spleen weights* mean (±1 *S.D.*)	Relative liver weights* mean (±1 *S.D.*)
I Cells from donors treated with ALS IgG	6	42.5 (±7.7)	568.7 (±47.1)
II Cells from donors treated with ALS $F(ab')_2$	5	128.5 (±23.9)	752.4 (±55.4)
III Cells from donors treated with NRS IgG	5	108.0 (±8.3)	698.8 (±54.6)
IV Cells from donors treated with NRS $F(ab')_2$	5	120.3 (±8.1)	637.6 (±49.9)
V Cells from donors treated with saline	5	120.9 (±7.3)	746.1 (±57.3)
VI Saline only	7	43.1 (±19.2)	585.7 (±31.9)

In vivo and *in vitro* Effect of Anti-lymphocytic IgG on Sensitized Spleen Cells

It has been shown that treatment of a number of animals with species specific anti-lymphocytic antibody suppresses their primary immune response to a variety of antigens[1]. Cell transfer experiments have also shown that "non-sensitized" lymphoid tissue from mice treated with anti-lymphocytic antibody can exhibit a reduced immunological potential when transferred to suitably prepared recipients[2-5]. Furthermore, suppression of suspensions of sensitized mouse and rabbit lymphoid cells can also be achieved by incubating them *in vitro* with anti-lymphocytic antibody before transferring them to test recipients[6,7]. In order to confirm and extend these previous cell transfer results, preliminary experiments have been undertaken to determine the effect of anti-rat lymphocyte antibody treatment (*in vivo* and *in vitro*) on the humoral antibody producing potential of sensitized rat spleen cells on subsequent transfer to irradiated recipients.

The suspensions of sensitized spleen cells were prepared from female rats of a hooded strain which had received two intraperitoneal injections of 5 mg of alum precipitated bovine serum albumin (alum BSA), 6 weeks and 2 weeks before the spleen was removed. The preparation and

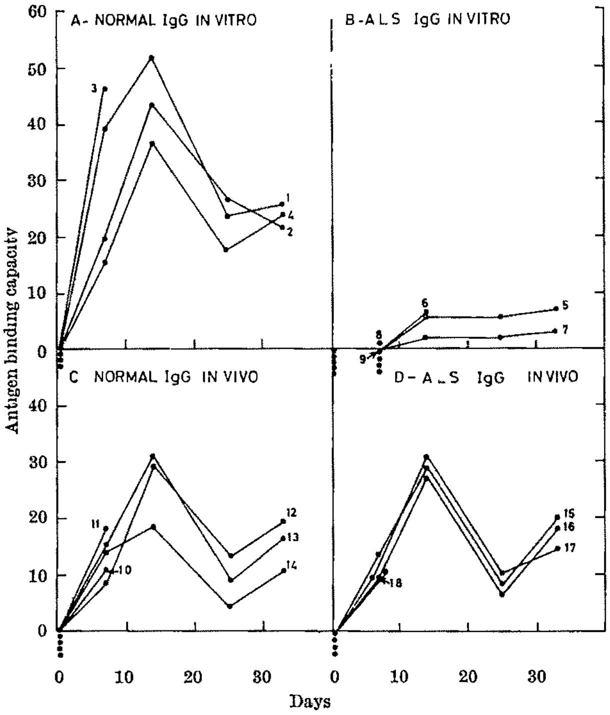

Fig 1 The effect of *in vivo* and *in vitro* anti-lymphocytic antibody treatment of sensitized spleen cells on their subsequent response to sensitizing antigen (BSA) following transfer to irradiated recipients For further details of the treatment of the sensitized spleen cells see the text Note that several animals died during the course of the experiment

properties of the horse anti-rat lymphocyte IgG and normal horse IgG have been reported elsewhere[8–10]

The *in vitro* treatment of suspensions of the sensitized spleen cells consisted of incubating them for 1 h at 37° C in sterile 0 15 molar solutions of sodium chloride containing normal horse or anti-lymphocytic IgG (1 mg of protein/ml) No extraneous complement was added to the mixture[6] Each incubation mixture (total volume 20 ml) contained cells from six spleens The *in vivo* treatment consisted of injecting (intraperitoneally) the sensitized animals daily with 2 ml of a 1 g per cent solution of the normal or the anti-lymphocytic IgG on the 3 days before the spleen was removed These cells were incubated in sterile saline alone All suspensions were washed twice following incubation and were made up to a volume of 7 ml (equivalent to six spleens)

Table 1 DETAILS OF THE TRANSFERRED SPLEEN CELL SUSPENSIONS

Experimental group	Treatment of sensitized spleen cells	Number of cells transferred	Percentage viable
A	Normal horse IgG *in vitro*	200×10^6	50
B	Horse anti-rat lymphocyte IgG *in vitro*	150×10^6	40
C	Normal horse IgG *in vivo*	200×10^6	80
D	Horse anti-rat lymphocyte IgG *in vivo*	150×10^6	54

The recipients of the various suspensions of sensitized spleen cells were 3–6 month old male rats of the hooded strain weighing from 200–390 g They all received terramycin in their drinking water (1 mg/100 ml) commencing 2 days before receiving 600 rads of whole body X-irradiation This dose of radiation had previously been shown to suppress completely the primary response of hooded male rats to alum BSA Twenty-four hours after irradiation the rats received an intraperitoneal injection of 1 ml of one of the suspensions of spleen cells (see Table 1) A further 24 h after cell transfer the animals were injected intraperitoneally with 5 mg of alum BSA The animals were bled 7, 14, 25 and 33 days after injection of antigen and the serum antibodies were determined by the Farr procedure[11] using an iodine-131 labelled BSA preparation containing 0 2 μg of nitrogen in each test Further details on the preparation of labelled antigen[12] and the Farr technique are recorded elsewhere[13]

It is apparent from Fig 1*B* that the treatment of sensitized spleen cells *in vitro* with anti-lymphocytic IgG markedly inhibits their subsequent response to alum BSA following transfer to X-irradiated recipients In contrast, the animals (Fig 1*A*, *C* and *D*) which received the other suspensions of spleen cells showed a characteristic secondary response to the bovine serum albumin[9]

The suppression of the humoral antibody response of sensitized lymphoid cells by *in vitro* treatment with anti-lymphocytic antibody confirms previous results in other species[6,7] These observations suggest that this form of treatment could be capable of erasing immunological memory, presumably as a result of direct interaction between memory cells and antibody It is appreciated, however, that alternative explanations exist including the rapid destruction of transferred antibody coated cells, their poor "seeding" and reduced proliferation Furthermore, one also has to take into consideration the fact that the animals in group *B* received fewer viable cells than those in group *A* although a comparison of the results between groups *C* and *D* would suggest that this was not a principal factor

The *in vivo* results support previous observations in rats[9,10] where a similar dose of anti-lymphocytic antibody did not have a marked effect on the secondary response of rats to alum BSA (ref 9) and also failed to suppress the primary response if given a short while after the antigen[10] It has been suggested that *in vivo* the anti-lymphocytic IgG has limited access to central lymphoid tissue such as the spleen and lymph nodes[7] and that its effect is primarily on peripheral lymphocytes[5] Thus the antibody is unable to inactivate memory cells or prevent plasma cell proliferation in these sites In contrast, however, it should be emphasized that studies on skin allograft rejection[5] and the graft versus host phenomenon[2–4] indicate that *in vivo* treatment with antilymphocytic antibody can significantly modify the subsequent immunological response of non-sensitized lymphoid tissue

Further experiments are now under way to confirm these preliminary observations using larger numbers of animals and transferring identical numbers of viable cells

I thank Dr N F Anderson for irradiating the rats, Mrs V James, Miss E Nelson and Mr A Wood for technical assistance, and Mr C Shepley for preparing the diagram I also thank Professor M F A Woodruff and Dr R N Pinckard for their advice and interest in this work

Proliferation of Mast Cells after Antigenic Stimulation in Adult Rats

IN the course of a series of experiments using tritiated thymidine to study long-lived lymphocytes and plasma cells in rat lymph nodes[1-3] we have frequently found a high percentage of labelled mast cells Because these findings seem inconsistent with reports that mast cells are stable and only divide slowly[4-6], we have re-examined our earlier experiments and have found evidence which shows that mast cells are actively produced after antigenic stimuli

The details of all the experiments to be considered have been previously reported In one group of experiments tritiated thymidine was injected twice daily for 2 days into the hind foot pads of 4–6 month old unstimulated rats or into similar rats on the third and fourth days after primary or secondary injections of 50 μg of *Salmonella adelaide* flagella[1] In subsequent experiments 2–3 month old rats were similarly injected with tritiated thymidine for the first 4 days after secondary stimuli with 0 10 or 0 25 ml of typhoid–paratyphoid A and B vaccine (TAB vaccine)[2,3] Thirty or 31 days after the last dose of tritiated thymidine had been given, rats of the latter group were exposed to 850 rads of X-irradiation[2], or to progressively increasing daily doses of prednisone, cyclophosphamide, 6-mercaptopurine or actinomycin *D* (ref 3) Pairs of rats were killed at various times after labelling with tritiated thymidine, 3 days after X-irradiation, and at intervals during drug administration Autoradiographs of smears of cells which had been teased from each popliteal node were prepared using Kodak *AR* 10 stripping film and Giemsa stain

For the studies which are reported here mast cells were identified on each autoradiograph by the unique colour of the cytoplasmic granules The labelling index for mast cells—that is, the percentage of mast cells with five or more grains/nucleus—was determined by counting fifty or one hundred cells on each smear Individual grain counts of thirty labelled mast cells/smear, or as many as could be found, occasionally less than ten, were used to determine collectively the median grain count for each identically treated group of rats For statistical analysis, the data were expressed as the ratio of labelled cells unlabelled cells, and the value of χ^2 was calculated from these ratios

Fig 1 shows the ranges and mean values for the labelling index of mast cells in popliteal nodes at various times after labelling in two different experiments When tritiated thymidine was given on the third and fourth days after a secondary stimulus of *Salmonella* flagella, the initial labelling index of the mast cells did not exceed 2 per cent Twenty-one days after the last dose of tritiated thymidine was administered, however, the labelling index increased to values as high as 22 per cent When tritiated thymidine was injected on days 1–4 after a secondary stimulus of TAB vaccine, the initial labelling indices were the highest which were found and exceeded any of those of the first experiment In both experiments, labelled mast cells were found months after the last dose of tritiated thymidine had been given, and in each case, after the initial 2 weeks, the median grain counts of the labelled mast cells decreased only slightly, indicating a stable, non-dividing population

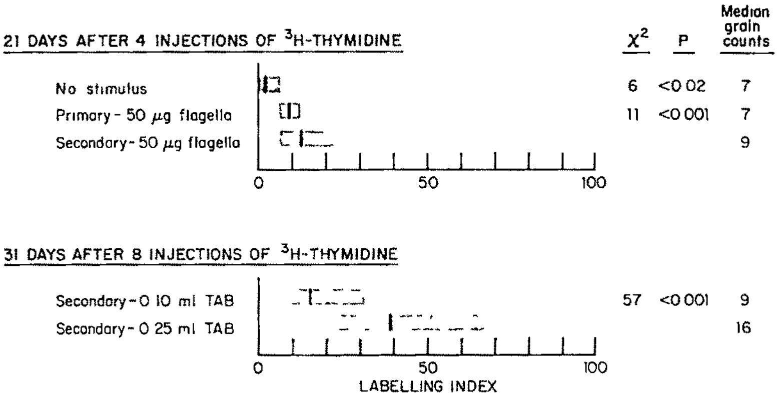

Fig 2 Histogram showing the ranges and mean values of the labelling index of mast cells in the popliteal lymph nodes after different types and degrees of immunological stimulation and after the two different courses of tritiated thymidine injections The values for χ^2 and P in the first group of experiments were calculated from the ratio of labelled unlabelled mast cells in the primarily stimulated lymph nodes compared with the non-stimulated lymph nodes, and from the secondarily stimulated lymph nodes compared with the non-stimulated nodes The median grain counts of the labelled mast cells which were present in the first experiment are considered to indicate similar degrees of labelling in each of the three groups

Fig 2 compares the range and mean values for the labelling index of mast cells 21 days after tritiated thymidine had been administered during a 2 day course when all values were highest in this experiment There were significantly greater proportions of labelled mast cells in nodes which were stimulated before labelling than in unstimulated nodes The difference between the labelling indices following a primary and those following a secondary stimulus was not significant Only one time point, 31 days after labelling, was available for comparing the labelling indices of mast cells after different secondary doses of TAB vaccine had been given A significant increase in the proportion of mast cells which were labelled after a stimulus of 0 25 ml of TAB vaccine was found compared with the proportion which were labelled after a stimulus of 0 10 ml (Fig 2) There was also an increase in the median grain count with the larger dose of TAB vaccine, despite the fact that an identical dose of tritiated thymidine had been given

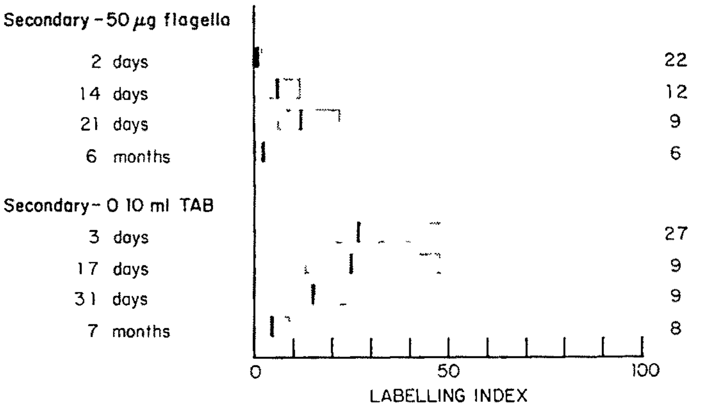

Fig 1 Histogram showing the ranges (shaded areas) and means (dark lines) of the values of the labelling indices of mast cells in popliteal lymph nodes at various times after the last dose of tritiated thymidine was administered in two experiments In the first experiment the tritiated thymidine was given in four injections in each foot pad on the third and fourth days after a secondary stimulus of 50 μg of *Salmonella* flagella In the second experiment the tritiated thymidine was given in eight injections in each foot pad on days 1–4 following a secondary stimulus of 0 10 ml of TAB vaccine The median grain counts of the labelled mast cells which were present at each time are also shown and are discussed in the text

The labelling index of mast cells in popliteal nodes of rats 33 days after labelling and 3 days after exposure to 850 rads of X-irradiation was significantly decreased in comparison with values from non-irradiated, control rats (Fig 3) Because the labelling index does not represent absolute numbers, it is not known whether the decrease in labelling index indicates radio-sensitivity of the labelled, long-lived mast cells or proliferation of new, unlabelled cells Fig 3 also shows that treatment of rats for up to 4 weeks with prednisone, cyclophosphamide, 6-mercaptopurine or actinomycin *D* did not change the labelling indices of mast cells At this time all the rats had signs of drug toxicity[3]

This work shows that mast cells actively proliferate after antigenic stimulation and that this proliferation is at least partly dependent on the degree of the stimulus The data also confirm, however, the earlier reports that mast cells, once mature, are long-lived and stable[5,6]. The labelling index and median grain counts of the mast cells decreased only over long periods of time, and none of the cytotoxic drugs, only X-irradiation, caused any change in the labelling index

Combs *et al* [7] have shown that mast cells in the foetal rat proliferate both from unidentified precursor cells and by mitosis of identifiable, but immature, mast cells Our data suggest that two mechanisms for mast cell proliferation could also exist in adult rats The delay of 21 days before the appearance of maximum labelling index following an injection of *Salmonella* flagella is best explained by assuming that cells which are not identifiable as mast cells were stimulated to divide and slowly differentiate The rapid appearance of large numbers of labelled mast cells after injection of TAB vaccine containing endotoxin, however, is more consistent with stimulation and division of mast cells themselves

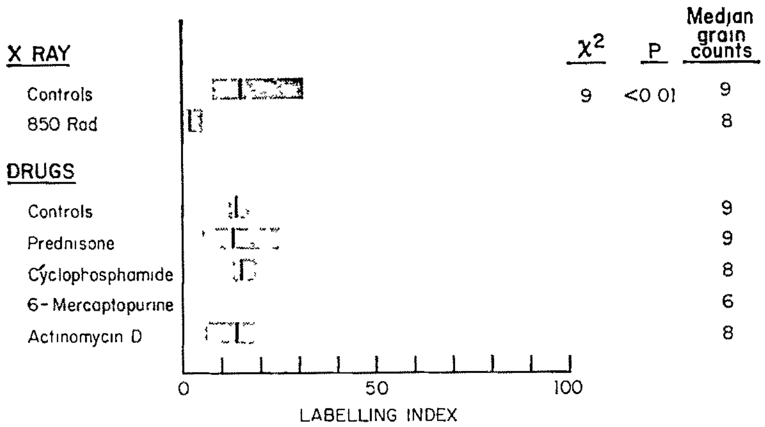

Fig 3 Histogram showing the ranges and mean values of labelling index of mast cells in popliteal lymph nodes after varied cytotoxic treatment The X-irradiation was given 30 days after irradiation The values for χ^2 and *P* were calculated for the ratios of labelled unlabelled cells in the control and irradiated groups of rats The drugs were given in progressively increasing doses intraperitoneally starting 30 days after labelling[3] The data shown are from rats which were killed after having received drugs for 4 weeks All the rats showed evidence of drug toxicity at this time The differences in labelling indices among the various drug-treated groups are not significant

In summary, the percentage of mast cells which were labelled after tritiated thymidine had been administered increased if the labelling followed antigenic stimulation This increase was in part dependent on the degree of the stimulus. The percentage of long-lived mast cells in lymph nodes decreased after X-irradiation, but not during treatment with several cytotoxic drugs

Sir Macfarlane Burnet suggested this work and, with Dr G J V Nossal, provided criticism of the early parts of it Dr Edward L Alpen provided criticism of the manuscript The study was supported in part by a grant to Dr G J V Nossal from the US National Institutes of Health, and in part by funds provided by the Bureau of Medicine and Surgery, US Navy Department

Analysis of Antibodies against Synthetic Angiotensin II by the Passive Haemagglutination Technique

FOR passive haemagglutination studies, antigens are usually adsorbed to tanned[1], formalinized[2-5], glutaraldehyde-fixed[6] or chromium chloride-treated red cells[7] Alternatively, antigenic material can be covalently bound to native or fixed erythrocytes by various coupling reagents, including bis-diazotized benzidine[8-11], 1,3-difluoro-4,6-dinitrobenzene[12], tolylene-2,4-diisocyanate[13] and carbodiimide (CDI)[14].

Several of the techniques are rather elaborate and have many limitations and difficulties, and so we chose to assay haemagglutinating antibodies against synthetic angiotensin II The octapeptide was coupled to native sheep red cells by means of CDI Furthermore, immune agglutination of peptide-treated red cells was used to investigate antigenic determinants of angiotensin II

Sheep blood was collected in modified Alsever's solution (compare ref 16) Red cells (SRBC) were washed three times with phosphate buffered saline (PBS) and standardized photometrically To each of four tubes containing 24 8 ml of distilled water 0 2 ml of an approximately 25 per cent (v/v) SRBC suspension was added and the average absorbency ($A_{\bar{x}}$) was determined in an Eppendorf photometer (filter 546) Corrections for volume were made in accordance with the relationship $V_f = V_i\, A_x/0\ 350$ (V_f, final, V_i, initial volume)

Suspensions contained $4\ 4 \times 10^9$ cells/ml as determined by Coulter counting For haemagglutination tests, photometrically standardized suspensions were prepared to contain $2\ 4 \times 10^8$ cells/ml

Synthetic Asp $(\mathrm{NH_2})^1$-Val^5-angiotensin II ('Hypertensin', Ciba) (AII) was conjugated to native erythrocytes by 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (CDI) (Ott Chemical Co) In multifactorial-type experiments optimal concentrations of SRBC, AII and CDI were determined, always using the same rabbit anti-AII serum pool CDI concentrations greater than 10 mg/ml caused haemolysis, whereas an excess of AII was associated with agglutination during coupling For a variety of concentrations of AII and a constant amount of CDI (10 mg/ml) a 25 per cent SRBC suspension yielded optimal conjugation conditions, judged by haemagglutinin titres The following procedure was finally adopted equal volumes of standardized 25 per cent cell suspension, AII (10 mg/ml PBS) and freshly dissolved CDI (10 mg/ml PBS) were added in this order, the mixture being kept at room temperature for 60 min with frequent stirring After incubation the cells were washed twice with EDTA. Cells coated with angiotensin and otherwise identically treated control cells without peptide, referred to as AII-CDI-SRBC and CDI-SRBC, respectively, could be stored for at least 15 days at 4° C without any detectable change in performance.

Haemagglutination was determined using the Takatsy outfit (Cooke Engineering Co.). To 0.025 ml. of serum, diluted in EDTA, 0.025 ml. of standardized (0.8 per cent) AII-CDI-SRBC or CDI-SRBC (in EDTA) was added. The plates were incubated overnight at 4° C. The extent of agglutination was scored from 4+ to negative[16]. Titres were expressed as logarithms to the base 2 of the reciprocal of the final dilution showing agglutination. All reactions were carried out in triplicate or quadruplicate and the following controls were always included: test sera were assayed against CDI-SRBC (containing no peptide), and the erythrocytes coated with peptides were tested with normal serum and with diluent only.

Antisera against AII were obtained after multiple injections of AII-CDI-protein conjugates incorporated in complete Freund's adjuvant[15,17] or after administration of AII-CDI-SRBC prepared as already described. Rabbits and chickens were injected on days 0, 1 and 10 with 1 ml. of a 10 per cent (v/v) cell suspension, given intravenously. Five days after the last injection the sera of both species exhibited specific anti-AII haemagglutinin titres of 5 and 6.

All the antisera used for haemagglutination were heat-inactivated and absorbed with SRBC and CDI-SRBC. Normal control sera were heat-inactivated and absorbed with SRBC only. Absorption of antisera with CDI-SRBC was essential, for haemagglutination regularly revealed antibodies to CDI or to CDI-erythrocyte determinants, whereas the presence of these antibodies could not be demonstrated immunochemically[15]. As compared with anti-AII, antibodies directed against CDI caused quantitatively and qualitatively different haemagglutination reactions. Instead of an evenly dispersed film of red cell agglutinates covering the bottom of the wells, 4+ patterns of anti-CDI were characterized by coarse cellular aggregates of different size and shape, localized in the central parts of the wells.

For haemagglutination inhibition tests, AII or its analogues and fragments were diluted in EDTA containing 1 per cent normal inactivated rabbit serum (NRS) which had been absorbed with SRBC. Two-fold serial dilutions of the peptide inhibitor were made in two groups of four rows each, each group beginning with a different concentration to give staggered endpoints. To 0.025 ml. of various dilutions of inhibitor, 0.025 ml. of rabbit anti-AII-CDI-protein diluted 1 : 64 in EDTA-NRS was added, the mixture was incubated for 30 min at 37° C. Finally, 0.025 ml. of a 0.8 per cent standardized AII-CDI-SRBC suspension was added and the plates were incubated overnight at 4° C. The smallest amount of AII, analogue or fragment, respectively, which caused complete inhibition of haemagglutination was considered to be the endpoint (extinction concentration, EC).

Results of inhibition tests are shown in Table 1. On a molecular basis, analogues or a fragment of AII differing from AII only in the N-terminal position 1 inhibited haemagglutination almost to the same extent as AII. The hexapeptide 3–8, lacking positions 1 and 2, and two analogues differing from AII in positions 4 and 5 showed a somewhat reduced inhibitory effect. On the other hand, the heptapeptide-amide 1–7, lacking the C-terminal phenylalanyl residue, inhibited haemagglutination to a much reduced extent.

Table 1. ANALYSIS OF ANTIBODIES AGAINST ANGIOTENSIN II BY HAEMAGGLUTINATION INHIBITION TESTS

Inhibitor	EC (p-mole)†	Relative EC‡
Asp $(NH_2)^1$ Val^5-angiotensin II*	2.9	1.0
β-L-Asp^1 Val^5-angiotensin II	3.9	1.3
β-D-Asp^1 Val^5-angiotensin II	5.2	1.8
$Succinyl^1$ Val^5-angiotensin II	5.5	1.9
Heptapeptide 2–8	5.8	2.0
Hexapeptide 3–8	15.4	5.3
Asp $(NH_2)^1$ Ile^5-angiotensin II	18.6	6.4
Asp $(NH_2)^1$ Phe^4-angiotensin II	18.5	6.4
Heptapeptide-amide 1–7	966.6	333.3

* Asp $(NH_2)^1$-Arg^2-Val^3-Tyr^4-Val^5-His^6-Pro^7-Phe^8 (Hypertensin, Ciba).
† Extinction concentration (10^{-12} mole).
‡ EC/EC_{AII}.

These results confirm previous findings[15,18] obtained by different techniques and stress again the great importance of the C-terminal phenylalanine and the relative unimportance of the N-terminal for immunological specificity.

Mechanisms in Early and Late Phases of Tolerance induced by Parabiosis in Adult Mice

PARABIOSIS between *CBAT6T6* inbred mice with the $(CBA \times C3H)F_1$ hybrid $(=T6\sim F_1)$ ($\sim$ is the symbol for parabiosis) gives considerable latitude in the study of the early phase of non-reactivity (specific immunological tolerance) induced by antigen because the cross circulation develops slowly between the partners[1] and the *CBA* and *C3H* inbred mouse strains from which the partners are derived are identical at the *H-2* histocompatibility locus. This constitutes a weak antigenic combination and, in conjunction with the gradual appearance of the cross circulation, the resulting (one-way[2]) immunological reaction between the partners is mild, so that many survive for subsequent study of the mechanism by which tolerance of the foreign antigens present in the hybrid partner is induced in the parental partner.

Clearance of $(CBA \times C3H)F_1$ hybrid erythrocytes labelled with chromium-51 suggested that the parental partner was sensitized to the *C3H* antigens of the F_1 hybrid partner early in parabiosis and before tolerance (judged by skin graft survival, to be discussed later) appeared. $(CBA \times C3H)F_1$ hybrid blood was washed once in phosphate buffered saline and 0.5 ml. of sodium chromate-51 isotope, with 0.05 mc. of activity/ml., was added to 0·5 ml. of packed cells and incubated at 37° C for 20 min. The cells were washed three times in phosphate buffered saline to remove free label and 0.04 ml. of labelled cells was injected intravenously into the parental partner. Equilibrium between the two partners appeared within a few hours. Samples of tail blood (0.02 ml. from each) were taken on alternate days, lysed in distilled water and the activity of both samples was measured in a well-type scintillation counter. The sum of each was expressed as percentage decay compared with the sum of a sample

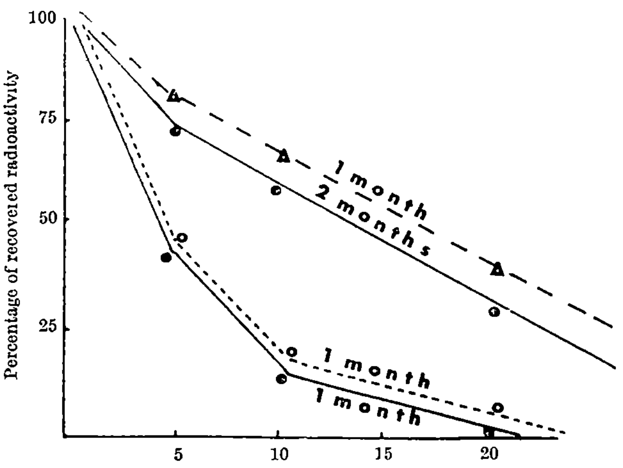

Fig 1 Elimination of chromium-51 labelled F_1 hybrid erythrocytes in parabiosis ●—●, $T6 \sim F_1$, ○ - - - ○, $T6 \sim T6$, △ - - - △, $F_1 \sim F_1$

taken 10 min after the first injection Convincing arguments against re-utilization of isotope complicating the issue have been put forward by Bainbridge *et al* [3]

In syngeneic $F_1 \sim F_1$ parabionts, elimination was always as expected from the known time of survival of mouse erythrocytes (28–35 days) Syngeneic $T6 \sim T6$ partners eliminated most of the labelled cells by 10 days In $T6 \sim F_1$ partners in parabiosis for 1 month, elimination (which presumably occurred in the parental partner) was the same as in $T6 \sim T6$ syngeneic parabionts After 2 months in parabiosis, elimination was the same as for $F1 \sim F1$ parabionts (Fig 1)

Sensitization in mice to foreign transplantation antigens to which they have previously been exposed can be detected by the accelerated rejection of skin grafts of the same genotype as the sensitizing antigen Mice were therefore parabiosed and separated at short intervals and the parental partner grafted with F_1 hybrid skin After a month in parabiosis, *C3H* parental partners rejected F_1 hybrid skin grafts in 9 days, which is the same as the second set rejection in single sensitized *C3H* mice (Table 1) It was not possible to demonstrate sensitization by accelerated skin graft rejection in *CBAT 6T6* parental partners Thus the sequence of events in both these experimental systems supports the suggestion that the parental partner goes through a period of sensitization to the foreign transplantation antigens of the hybrid partner (to which they subsequently become tolerant) during the early phases of parabiosis by recirculation of parental lymphoid cells which have been sensitized in the F_1 hybrid partner[4,5]

Table 1 REJECTION TIMES IN DAYS (EP) OF *CBAT6T6* AND *C3H* PARENTAL PARABIONTS GRAFTED WITH $(CBA \times C3H)F_1$ HYBRID SKIN

53	—	> 133

		First set	Second set
Rejection times in parental strain mice	*CBA*→*C3H*	12	9
	C3H→*CBA*	11	8

Sensitization of *CBAT6T6* parental partners was studied further by estimating the "immunological potential" of spleen cells from parabionts after various times in parabiosis in lethally irradiated $(CBA \times C3H)F_1$ hybrids It was argued that sensitized *CBAT6T6* parabiont cells would cause rapid death by the severity of the graft versus host reaction No antibiotics were given to the irradiated mice and only intravenously injected spleen cells which are well known to contain all the necessary stem cells were used to restore them Several experiments tended to show that reactive parental cells were sensitized in the hybrid partner in the early phase of parabiosis and rendered tolerant in the later phase

Table 2 shows the effect of treatment with spleen cells from highly tolerant parabionts on lethally irradiated hybrids compared with similar hybrids treated with normal parental and hybrid spleen cells in doses of 1×10^6 and 5×10^6 cells By 14 days a graft versus host reaction had killed nearly all the hybrids treated with normal *CBAT6T6* spleen cells at both doses Those given 1×10^6 cells just managed to survive for 14 days and because it was clear they would not live for longer than a day or so they were killed at this time Mortality was eliminated with spleen cells from tolerant and F_1 hybrid mice and none died during the following 10 weeks Table 3 gives results of another experiment showing a similar pattern of long term survival of the restored irradiated hybrids, but in this case several irradiated F_1 hybrids given normal *T*6 spleen cells survived, probably because of the weak antigenic combination In this situation, secondary irradiation disease need not always be uniformly lethal[6]

Table 2 POTENTIAL OF GRADED DOSES OF PARABIONT SPLEEN CELLS IN RESTORING LETHALLY (1,000 R) IRRADIATED F_1 HYBRIDS

Survival/number at 14 days

No of cells	Source of spleen cells		
	Tolerant	Normal	Normal F_1
1×10^6	7/8	6/6*	5/5
5×10^6	9/9	1/11	5/5

* All moribund

Table 3 WEEKLY SURVIVAL OF IRRADIATED F_1 HYBRIDS RESTORED WITH SPLEEN CELLS FROM TOLERANT, NORMAL *CBAT6T6* AND F_1 HYBRID MICE

Weeks	0	1	2	3	4	5	6	6+
Tol	20	20	19	14	14	14	14	14

F_1	15	15	15	15	15	15	15	15

5×10^6 spleen cells were injected intravenously.

The effect of *CBAT6T6* parabiont spleen cells after 9, 17 and 28 days in parabiosis in irradiated F_1 hybrids is shown in Table 4 No deaths occurred in the hybrid hosts treated with 9 day parental spleen cells Apart from the considerations about the mortality in irradiation chimaeras mentioned here, it is tempting to suggest that this represents a low zone of dosage causing paralysis as in other systems[7-9] The induction of tolerance in the later stages of parabiosis would then represent the high zone of dosage following a period of sensitization Spleen cells from 17 day old parental parabionts caused a 100 per cent mortality by 2 weeks, undoubtedly because of parental lymphoid cells sensitized against the *C3H* element in the hybrid which have recirculated to the parental partner Elimination of mortality after 28 days in parabiosis suggests that tolerance is appearing

Table 4 WEEKLY SURVIVAL OF IRRADIATED F_1 HYBRIDS RESTORED WITH SPLEEN CELLS FROM *CBAT6T6* PARABIONTS, SEPARATED AT INTERVALS OF 9, 17 AND 28 DAYS

Days in parabiosis	Weeks 0	1	2	3	4	5	6	6+
9	5	5	5	5	5	5	5	4
17	10	10	5	0				
28	5	5	5	5	5	5	5	5

It is concluded that in the strain combinations used here the parental partner becomes sensitized to hybrid antigens before the state of tolerance appears Other workers have shown that single post-natal mice injected with foreign cells go through a phase of sensitization before becoming tolerant[10,11] Further experiments are being conducted in parabiosis systems (transference of the tolerant state, for example) to try to find out whether the tolerant state is caused by elimination or paralysis of reactive lymphoid cells

MICROBIOLOGY

In vitro Agglutination of Bovine Erythrocytes infected with *Babesia argentina*

THE presence of antibodies capable of agglutinating intracellular schizonts of *Plasmodium knowlesi* has been reported[1] and a parasite agglutination test described[1-2] This communication reports a similar test for *Babesia argentina* using heavily parasitized bovine erythrocytes

Splenectomized calves, 3–6 months old, were infected with *B argentina* by intravenous inoculation of blood from carrier cattle When 2 per cent of the erythrocytes in jugular blood were infected, blood was collected in bottles containing EDTA (disodium salt of ethylenediamine tetraacetic acid) as anticoagulant If the peak parasitaemia was below this level, blood was transferred to another splenectomized calf and the procedure repeated until the 2 per cent parasitaemia was obtained

One per cent erythrocyte suspensions in physiological saline were prepared which contained approximately 80 per cent of their cells infected with *B argentina* The infected cells were first concentrated from parasitized blood by a method described by Mahoney[3] Appropriate control suspensions were also prepared from normal blood taken from each calf before infection These suspensions of infected and uninfected cells were used as antigens for the agglutination test

The agglutination test was conducted in 'Perspex' haemagglutination trays Sera were diluted 1/5 in physiological saline containing 1 per cent normal calf serum and heated at 56° C for 30 min Doubling dilutions of serum were prepared and to 0 2 ml of each dilution an equal volume of the infected cell suspension was added A control test using the uninfected cell suspension was included with each serum The plates were shaken and allowed to stand at room temperature for 3 h

Reactions were read macroscopically and microscopically (× 100), the latter after resuspending by gentle shaking. Macroscopic reactions were graded as follows + + + +, a mat of cells completely covering the bottom of the cavity without any ring of cells around its periphery The surface had a granular appearance and the edges of the mat were sometimes folded, + + +, similar to the + + + + reaction but with a thin ring of cells around the periphery, + +, a distinct ring of cells with only a slight granular appearance, +, a thick ring of cells with a diameter approximately half that of the mat in the + + + + reaction, ± or –, a discrete button or thick ring of cells was present

The titre of the serum was taken as the highest dilution showing a + + reaction macroscopically

Microscopically the amount of agglutination was estimated at the 1/5 dilution as follows + + + +, many clumps of over 200 cells, + + +, many clumps of over 50 cells, + +, less numerous clumps of over 20 cells, +, odd clumps of less than 20 cells

Parasites from five isolations of *B argentina* from geographically separated natural outbreaks in New South Wales were used to prepare suspensions Isolates were maintained in individual carriers at the laboratory and designated with the name of the locality from which they came (Table 1) A sixth isolate (Gayndah) was obtained from Dr D F Mahoney, CSIRO, Yeerongpilly Occasionally before inoculation, parasites were preserved by freezing infected whole blood to –79° C and storing at this temperature

Antisera were collected from the same six carrier animals used to provide isolates for suspensions but were taken 2 to 6 weeks later They were stored at –20° C without preservative

The results of testing these suspensions with homologous and heterologous antisera are shown in Table 1. With each suspension the highest titre and greatest degree of clumping was obtained with the homologous antiserum Reactors with the heterologous antisera were slight.

Preliminary studies on the specificity of the reaction have been undertaken Of 450 non-infected animals tested with the Gayndah isolate suspension only four (0 9 per cent) showed any agglutination at the 1/10 dilution and only one (0 2 per cent) at the 1/20 dilution The greatest amount of clumping recorded was + + at the 1/5 dilution with one serum Similar results were obtained with 100 of these sera when tested with the other five isolate suspensions

The reaction appeared to be highly specific for each isolate The isolates used were possibly antigenic variants of one or more strains of *B argentina* arising by a process similar to that demonstrated by the agglutination test in chronic *P knowlesi* infections[2] The test described here is at present being used to investigate the possibility of similar antigenic variation in *B argentina* infections If basic strain antigens can be identified and strains of the parasite classified, the technique would be valuable in epidemiological studies

The effect of these agglutinating antibodies on immunity also needs to be investigated Agglutinins in *P knowlesi* were considered to be important in terminating relapses, but another immune response was also thought to be present and partially able to inhibit relapses[2] A similar state of affairs may exist with *B argentina* infections

Table 1 AGGLUTINATION TEST RESULTS OF SERA FROM SIX CATTLE INFECTED WITH SEPARATE ISOLATES OF *Babesia argentina* AGAINST ANTIGENS FROM THE SAME ANIMALS

		Antigen					
	Isolate	Gayndah	Cougal	Piggabeen	Dalguigan	Wiangaree	Roseberry
Serum	Gayndah	*1,250 (+ + + +)†	0 (–)	0 (–)	40 (+ +)	0 (–)	0 (–)
	Cougal	160 (+ +)	5,000 (+ + + +)	40 (+)	20 (+)	10 (+)	40 (+)
	Piggabeen	0 (–)	0 (–)	640 (+ + + +)	10 (+)	5 (+ +)	5 (+)
	Dalguigan	20 (+ +)	—	—	1,250 (+ + +)	0 (–)	40 (+ +)
	Wiangaree	0 (–)	0 (–)	0 (–)	0 (–)	320 (+ + + +)	0 (–)
	Roseberry	10 (+)	20 (+ +)	0 (–)	20 (+)	0 (–)	5,000 (+ + + +)

* Reciprocals of agglutination test titres

† Size and number of agglutinated clumps at the 1/5 serum dilution

It would seem that the development of an effective vaccine able to produce a sterile immunity for *B argentina* would depend on the importance of these antigens and their variability.

CYTOLOGY

Growth-promoting Effect of Lysolecithin on Chinese Hamster Cells *in vitro*

WHILE the importance of amino-acids[1,2], salts[3] and vitamins[4] for growth of mammalian cells in culture is well established, the role of lipids remains uncertain With the exception of free fatty acids[5], no naturally occurring lipids such as glycerides, phospholipids or cholesterol have been shown to promote growth of mammalian cells *in vitro*

Lysolecithin was until recently considered to be a toxic haemolysing substance generated in the blood by the action of snake venom In 1960, however, Lands[6] showed that lysolecithin was an intermediate in the synthesis of lecithin in rat liver homogenates Further, lysolecithin was found in both rat[7] and man[8] to be a normal constituent of plasma and to be associated exclusively with the albumin fraction[9] Stein and Stein[10,11] then showed that albumin-bound lysolecithin was incorporated by intact cells and utilized in the synthesis of lecithin

I have found that albumin-bound lysolecithin has a definite growth-promoting effect on Chinese hamster cells in culture The effect seems to be caused by the uptake of intact lysolecithin and not by breakdown products

The lysolecithin (Koch-Light Laboratories, Ltd), a 1-acyl phosphatidylcholine prepared from egg lecithin by degradation with snake venom phospholipase, was shown to be pure by thin layer chromatography Analysis by gas-liquid chromatography showed that 94 per cent of the fatty acid moiety was saturated, the principal components being palmitic acid (71 per cent) and stearic acid (21 per cent) The unsaturated acids (6 per cent) were chiefly oleic (2 per cent) and linoleic acid (2 per cent) Bovine plasma albumin (Armour, Fraction V) was extracted by the method of Goodman[12] and a lysolecithin-albumin complex was prepared and purified by the method of Stein and Stein[13]. The lysolecithin content of the albumin was determined by thin layer chromatography of the albumin phospholipids followed by phosphorus analysis[14]

Chinese hamster cells, line *CHEF*, were routinely grown in the Dulbecco-Vogt modification of Eagle's medium[15] supplemented with 20 per cent calf serum Experimental cultures were inoculated with 8×10^4 cells in each Petri dish (diameter 32 mm) in 1 5 ml of medium and allowed to attach After 4 h the medium was removed and the experimental medium added The plates were then incubated for 3 days Cell numbers were determined at the beginning and at the end of this period by counting the cells within five squares etched into the bottom of the plates

The experimental medium was identical with the usual medium except that it was free of serum and contained 1 per cent extracted albumin with and without added lysolecithin The final concentration of lysolecithin was 75 µmoles/l of medium, and the molar ratio of lysolecithin albumin was 1 2 (assumed molecular weight of albumin 67,000) Without addition the concentration of lysolecithin in the medium was less than 1 µmole/l

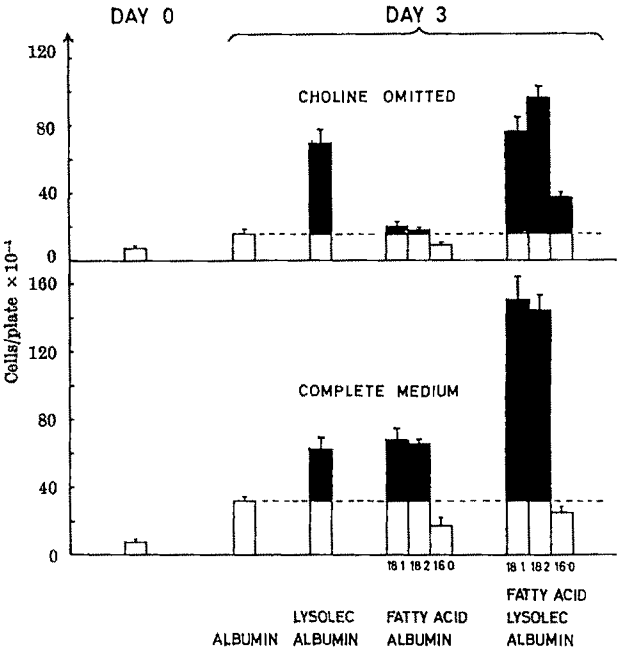

Fig 1 Effect of albumin-bound lysolecithin and fatty acids on growth of Chinese hamster cells *in vitro* The columns represent the average of four experiments each including eighteen plates, the vertical bars being the standard error of the mean The black portion of the columns indicates the increase in cell number due to the presence of albumin-bound lipid Oleic (18 1), linoleic (18 2) and palmitic (16 0) acids are designated by the number of carbon atoms and double bonds in the molecule[18]

The addition of lysolecithin to the medium (Fig 1) increased growth significantly ($P < 0\ 01$) This effect was evident both in the presence and absence of choline, but the effect was greater when choline was omitted from the medium

Fatty acids have been shown to promote growth of cells in culture[5] and some cells have lysolecithinases (acyl hydrolases) associated with their surfaces[11,16], so the question arose as to whether the growth-promoting effect was caused by free fatty acids liberated by the action of lipase or to the uptake of lysolecithin as such To examine this question individual high purity fatty acids (Applied Science Laboratories, Inc) were tried as substitutes for lysolecithin The fatty acids were combined with extracted albumin and their concentration determined by titration[17] The final medium contained 75 µmoles of free fatty acids/l , while without additions the concentration was less than 3 µmoles/l

In the presence of choline, the unsaturated acids, oleic and linoleic, stimulated growth markedly, whereas the saturated palmitic acid inhibited growth (Fig 1) About 94 per cent of the fatty acids of lysolecithin were saturated, and more than 70 per cent was palmitic acid, so that it seems unlikely that the observed effect of lysolecithin could be caused by its fatty acid moiety in the form of free fatty acid Furthermore, the maximal concentration of unsaturated free fatty acids attainable, if all the lysolecithin were hydrolysed, was found to be too low to promote growth (my unpublished results)

Lysolecithin has been found to be an intermediary in the synthesis of lecithin in other cells, and so these results suggest that lysolecithin stimulates growth by promoting synthesis of lecithin The following observation seems to support this hypothesis. Equimolar amounts of lysolecithin together with oleic or linoleic acid, in the complete medium, stimulated growth to a degree that exceeded the sum of their individual effects ($P < 0{\cdot}01$ by paired comparison) (Fig 1) This synergism suggests that lysolecithin and unsaturated fatty acids have a common mechanism of action. By direct combination, that is by acylation of lysolecithin as described by Lands, a diacylphosphorylcholine would be formed with a saturated 1-acyl and an unsaturated 2-acyl group, which is the naturally occurring form of lecithin. The inhibitory effect of palmitic acid suggests that the cells have a very limited capacity for desaturating fatty acids.

The notion that lecithin synthesis was important for cell proliferation was further supported by the following finding. The two unsaturated fatty acids caused increased growth only when choline was present—that is, when lecithin synthesis was possible, but not when lecithin synthesis was limited by the omission of choline from the medium (Fig. 1). Whether lecithin itself, when added to the medium, can promote growth is under investigation.

I thank Professor E. Zeuthen for reading the manuscript. This work was supported by the Danish State Research Foundation, the Carlsberg Foundation and Dobercks grant to the Biological Institute of the Carlsberg Foundation.

Odontogenesis: Cell–Cell Interactions *in vitro*

EMBRYONIC interactions of epithelial and mesenchymal tissue before organogenesis have been observed in several organ systems[1-4]. These phenomena have been tested by isolating embryonic tissues from their *in vivo* environment and transplanting them in an artificial environment from which no morphogenetic signals can be received. The chorio-allantoic membrane (CAM) of chick provides a versatile site for the maintenance and further differentiation of embryonic organs[5,6]. One such organ, the tooth primordium, arises as a result of interactions between epithelial and mesenchymal tissues and offers a model system for developmental studies.

Recently, studies of the trans-filter interaction of embryonic rodent incisor tissues have shown that overt differentiation occurs in both separated epithelial and mesenchymal tissues[7]. These results and those of numerous other investigators[8-12] suggest that the interaction of epithelial and mesenchymal tissues is essential for tooth formation.

To examine the morphogenetic potential of cells from these tissues, an experiment was designed to evaluate cell–cell interactions before histogenesis. Maxillary incisors were removed from the embryos of New Zealand white rabbits at the twentieth day of gestation. At this stage of tooth development both enamel and dentine formation have begun in the coronal portion of the organ, and most tissues which have been formed show various degrees of differentiation (Fig. 1).

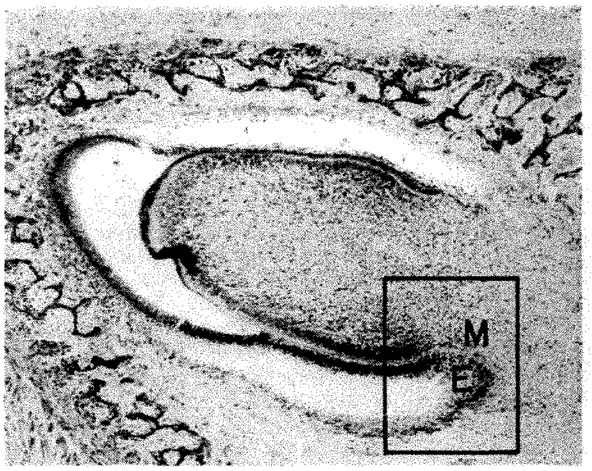

Fig. 1. Maxillary incisor in the embryo of New Zealand white rabbit at day 20 of gestation before excision. The whole tooth rudiment is encapsulated in alveolar bone. The rectangle contains the cervical loop region from which dissociated inner enamel epithelium and mesenchymal papillae cells were obtained. *E*, Epithelial cells; *M*, mesenchymal cells (× 50).

Apical or cervical regions of these incisor tooth germs were excised. The isolated cervical regions were trypsinized to dissociate the inner enamel epithelium from the mesodermal papilla by the methods of Moscona[13]. The isolated epithelial and mesenchymal tissues were further treated with 0·4 per cent trypsin to obtain single cell suspensions. The isolated cells, in a calcium-magnesium free phosphate buffered saline at *p*H 7·2, were pipetted onto the CAM of 8-day embryonated hens' eggs and incubated at 37·5° C for periods of up to 10 days. Three sets of experiments (twenty grafted eggs in a group) were used to test epithelial cells only, mesenchymal cells only and the interaction when both cell types were mixed together in culture. Tissue and cell dissociations were monitored by phase microscopy in order to ensure that there were relatively clean cell suspensions of both inner enamel epithelium and mesodermal papillae. At various periods during the experiment, xenogeneic cell preparations were dissected with the adjacent CAM and were immediately placed in Hollande-Bouin's solution. The tissues were sectioned at 5μ and stained with periodic acid–Schiff's (PAS) reagent. There is a variety of cell types within the original separated tissue preparations; it might therefore be anticipated that these originally dissimilar cells would display different patterns of mobility, differentiation and survival. The test for viability of the xenogeneic cells in these culture conditions was based upon the frequency of mitotic figures. Additional quantitation of the surviving epithelial and mesenchymal cell suspensions before and after the experiment has not yet been performed. The viability of the host chick embryo was determined by daily candling.

A positive interaction is considered to be represented by one or both cell types undergoing morphological differentiation.

When either one of the cell suspensions was cultivated independently on the CAM, no indication of tooth formation was observed (Fig. 2). Both homogeneous xenograft groups exhibited a continued proliferation of cells, reflected by numerous mitotic figures. The isolates appeared as randomly dispersed cells with neither apparent orientation nor continued differentiations; no re-aggregation of the isolates was observed.

When both cell preparations were mixed and suspended on the CAM, an induction was observed which resulted in the initiation of tooth formation (Fig. 3). A well defined PAS-positive interface, analogous to that reported to occur *in vivo*[14-15], separated the interacting cells. In several xenografts within this group, the cell–cell interaction was preceded by the bud stage of tooth development. The similarity between *in vivo* and *in vitro* development is shown by condensation of the mesenchymal cells, a specific PAS-positive future dentino-enamel junction, and regularity of the tall columnar inner enamel epithelial cells. The temporal differentiation of these epithelial cells is shown *in vivo* and *in vitro* by differentiation of squamous cells into cuboidal then columnar inner enamel epithelial cells with a subsequent alteration in nuclear polarity. The differentiation of the mesodermally derived odontoblasts is undoubtedly related to interaction with the inner enamel epithelium. Earlier workers had postulated this fundamental relationship, primarily because of the observed differentiation of inner enamel epithelium into ameloblasts before differentiation of odontoblasts[16-18]. The maximum duration of these experiments (10 days) might not allow sufficient time for the mesenchymal cells to differentiate into odontoblasts *in vitro*.

The analysis of these events during tooth development *in vitro* shows that the morphogenetic potential is closely related to the properties of both interacting cell types, not exclusive to either one. Thereafter, tooth formation must be regarded as a complex temporal differentiation involving both types of interacting cells. After re-aggregation, the events *in vitro* show a striking developmental similarity to those occurring *in vivo*.

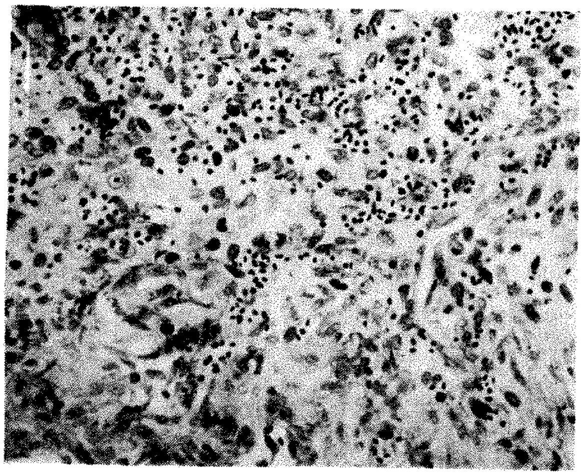

Fig. 2. Mesenchymal cell suspension explanted onto the CAM for 10 days of cultivation. The isolated cell suspensions of either mesenchymal or epithelial tissue fail to initiate tooth formation and do not re-aggregate or orientate when cultivated on the CAM (× *c*. 370).

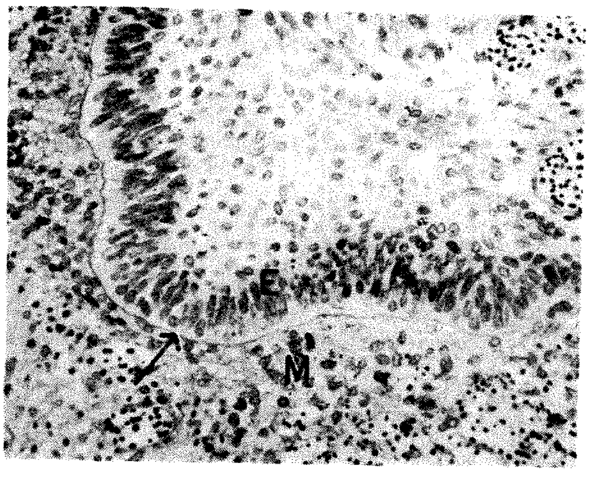

Fig. 3. When both cell preparations were mixed and cultivated for 10 days on the CAM, tooth formation was initiated. *E*, Inner enamel epithelium; *M*, mesenchymal papilla. Arrow points to PAS-positive future dentino-enamel junction (× *c*. 370).

This investigation was supported in part by a US Public Health Service grant, a training grant and a research career award to L. A. Bavetta, from the National Institute for Dental Research. We thank Drs S. Allerton and M. Nimni for help and encouragement, and Mrs Zoya Trirogoff for technical assistance.

PHYSIOLOGY

Sialotonin: Vasopressor Substance in Cat Submaxillary Saliva

THE potent vasodepressor effect of cat's submaxillary saliva after intravenous injection into the cat was first noted by Secker[1,2]. After some controversy about the alleged similarity of this substance to acetylcholine[3-5], it is now clear that it is a glycoprotein, that is salivary kallikrein[6,7].

The same workers[1-5] also occasionally observed an evanescent and variable vasopressor effect of cat's submaxillary saliva which preceded the depressor effect. The study of this apparent pressor agent was never pursued, probably because of difficulty in observing it with convincing regularity and in separating it chemically from the depressor substance, kallikrein.

We have now established the reasons for the erratic pressor (or hypertensive) effect of cat saliva when injected intravenously in the cat, and have separated it from kallikrein. The chief difficulty of studying this substance by its systemic pressor effect is that the vasoconstriction is confined to certain vascular areas, in particular the intestinal blood vessels.

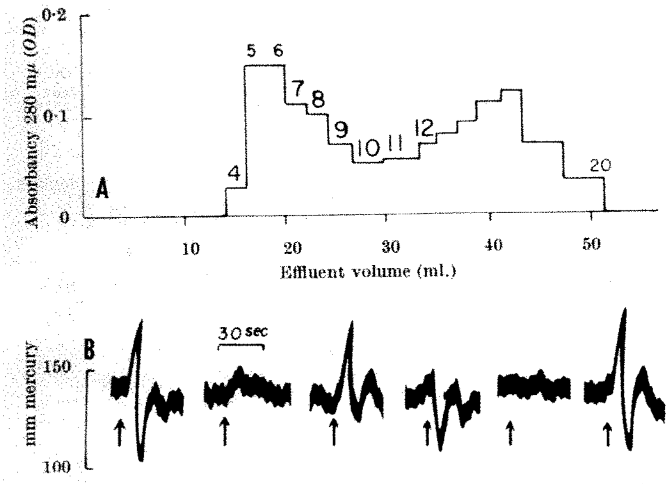
We have called this vasoconstrictor compound sialotonin. A substance which resembles it has been described by Werle and von Roden[8], who found a large-molecular hypertensive agent in extracts of the submaxillary gland of the dog but not of the cat. The arterial blood pressure of the dog rather than that of the cat was used to assay the substance.

Whereas kallikrein in submaxillary saliva is secreted in much higher concentrations with sympathetic than with chorda-lingual nerve stimulation[9], sialotonin is secreted only with chorda-lingual stimulation. Sialotonin was undetectable in saliva obtained by sympathetic nerve stimulation. Feldberg and Guimarais[3] also noted this relationship between nerve stimulation and the pressor and depressor effects of the respective salivas. We therefore obtained saliva by chorda-lingual nerve stimulation in order to study the pressor agent.

The intravenous injection of 0·02 ml. of chorda saliva (usual dose 0·2 ml., diluted 1 : 10) usually produced a sharp rise in arterial blood pressure lasting 5–15 sec, followed by a more prolonged fall caused by kallikrein. The increase in blood pressure varied from 25–50 mm of mercury and usually persisted with repeated injections. It was not affected significantly by the intravenous injection of atropine (500 µg/kg), phenoxybenzamine (500 µg/kg), hexamethonium (1 mg/kg) or carboxypeptidase *B* (3–4 mg/kg). It was abolished completely, however, if the diluted saliva was previously incubated with trypsin (100 µg/ml.) or chymotrypsin (100 µg/ml.) for 30 min. The increase in blood pressure was also usually reduced or abolished by laparotomy and gentle handling of the abdominal viscera of the cat used for the assay.

Sialotonin is a large-molecular compound, probably a protein or glycoprotein. It is heat-labile, non-dialysable and rapidly inactivated by incubation with trypsin or chymotrypsin (100 µg/ml., 30 min). Sialotonin and kallikrein were eluted in the same fractions of saliva applied to columns of 'Sephadex *G*-25' and '*G*-50.' A distinct separation was obtained, however, from columns of 'Sephadex *G*-100' after the application of cat's chorda saliva (usually diluted 1 : 2) in 0·15 molar NaCl as solvent. The optical densities of successive fractions from the column and their respective assays on the cat's arterial blood pressure are shown in Fig. 1. In this figure the original chorda saliva shows the vascular effects of both sialotonin (pressor) and kallikrein (depressor) whereas a distinct separation of these effects is seen in the pharmacological actions of fractions 7–8 and 9–11, respectively.

Whereas salivary kallikrein is readily obtained as a stable freeze-dried material, we have as yet not succeeded in preparing a stable, freeze-dried preparation of sialotonin. It is stable for months, however, if kept frozen in solution, either as the crude saliva or in eluates (in 0·15 molar NaCl) from columns of 'Sephadex'.



Sample:	Chorda saliva (1 : 10)	Fraction 4	Fractions 7–8	Fractions 9–11	Fraction 12	Chorda saliva (1 : 10)
OD of sample:	0·132	0·016	0·106	0·061	0·070	0·132
Injection vol. (ml., i.v.):	0·3	0·5	0·2	0·4	0·4	0·3

Fig. 1. *A*, Optical densities of successive fractions after application of cat's chorda saliva to a 1·5 × 20 cm column of 'Sephadex *G*-100'. The solvent was 0·15 molar NaCl, *p*H 8·2. *B*, Response of arterial blood pressure (cat) to intravenous injection of above fractions. Original chorda saliva shows activity of both sialotonin (pressor) and kallikrein (depressor). Sialotonin only, however, was present in fractions 5–8, whereas kallikrein appeared in fractions 9–11.

Using an electromagnetic flow-meter with the probe placed around different arteries, we made the following observations, which indicate that the effect of sialotonin on systemic arterial blood pressure after its intravenous injection is caused by a highly specific constrictor action which has so far been observed only on the vessels of the intestine. Injections of partially purified sialotonin, or of 0·002–0·02 ml. of diluted cat's chorda saliva, close-arterially, through the superior mesenteric artery, produced an immediate brief reduction (15–30 sec) in blood flow through this artery, indicating that the blood flow through the intestine was reduced by as much as 80 per cent. Similar experiments on blood flow through the lower limbs revealed no vasoconstrictor action of sialotonin. Our preliminary observations therefore suggest that the action of sialotonin is predominantly on the intestinal blood vessels. We are continuing the study of its vasoconstrictor action in more detail. So far, our studies failed to demonstrate a marked constrictor action of sialotonin on the blood vessels of the submaxillary gland itself.

Sialotonin can easily be distinguished from known pressor agents such as catecholamines, indolealkylamines, angiotensin and other relatively small-molecular compounds by its chemical and pharmacological properties. It is distinguishable from renin by the fact that it fails to release angiotensin on incubation with plasma and by its brief and regional vasoconstrictor effects. It does, however, resemble the hypertensive agent described by Werle and von Roden in extracts from the submaxillary gland of the dog[8].

We thank Dr C. V. Greenway for help in measuring regional blood-flows. This work was supported by grants from the Medical Research Council of Canada and the Alberta Heart Foundation.

Action of Iontophoretically Applied Tetrodotoxin on Cortical Nerve Cells

Tetrodotoxin is the potent poison found in puffer fish of the sub-order Gymnodontes and newts of the genus *Taricha*[1]. In low concentrations, tetrodotoxin suppresses action potentials in a variety of excitable tissues including frog myelinated nerve fibres, frog muscle fibres[2], lobster and squid giant axons[3,4] and cardiac muscle[5]. The action potentials of some other tissues, such as crustacean muscle fibres, the taenia coli and vas deferens of guinea-pigs are not affected by tetrodotoxin[6–8]. Although evoked potentials in the cerebral cortex are depressed by topically applied tetrodotoxin[9], its effect on action potentials of nerve cells in the central nervous system has not been demonstrated.

In previous investigations, tetrodotoxin has been applied in perfusion solutions or administered by intravascular injection. Iontophoretic application of drugs allows their site of action to be determined with greater certainty in complex structures such as the central nervous system. Tetrodotoxin has been used to study synaptic transmission at the neuromuscular junction[10]. Its interaction with various forms of excitation of cortical neurones has now been assessed.

Tetrodotoxin is an amino perhydroquinazoline compound with a molecular formula of $C_{11}H_{17}N_3O_8$. It is sparingly soluble in water as a monoacidic base[1]. In early experiments, one barrel of the multiple barrel micropipettes used in the investigation was filled with an aqueous solution of 10^{-3} g/ml. of tetrodotoxin (Sankyo Co., Ltd.). The activity of tetrodotoxin was so marked that it was impossible to prevent diffusion of excessive quantities from the electrode. Satisfactory application and diffusional control have been obtained by preparing solutions of 10^{-6} to 5×10^{-6} g/ml. tetrodotoxin in 200 mmolar sodium chloride. The passage of cation applying currents through such a solution seems to deliver small amounts of tetrodotoxin.

Tetrodotoxin depressed the excitability of cortical neurones. An example of tetrodotoxin depression of the invasion of an antidromic spike into a pyramidal tract neurone in the pre-cruciate cerebral cortex is shown in Fig. 1. The spike was considered to be antidromically propagated because it had a constant latency of 2·9 msec, followed medullary pyramid stimulation at frequencies of 300 stimuli/sec and had a refractory period for the cell soma of less than 2 msec (Fig. 1*B*). With shorter intervals between stimuli, invasion of the soma-dendritic spike failed, leaving the initial segment spike (Fig. 1*C*). Spike generation failed completely when the interval between stimuli was 1·2 msec (Fig. 1*D*). The application of minute amounts of tetrodotoxin caused a progressive graded reduction in the size of the antidromic spike and ultimately a complete failure of invasion (Fig. 1*E*). Recovery occurred within approximately 24 sec of the termination of tetrodotoxin application.

Tetrodotoxin also prevented the generation of synaptically evoked responses and reduced or abolished the excitant effects of L-glutamate and acetylcholine on cortical nerve cells. It did not affect the inhibitory actions of acetylcholine or 5-hydroxytryptamine. An example of depression of L-glutamate firing is shown in Fig. 2. Application of tetrodotoxin by a current of 20 n.amp for 40 sec more than halved the rate of firing evoked by standard pulses of L-glutamate. Recovery after application of tetrodotoxin took approximately 3 min. Larger currents passed through the barrel containing tetrodotoxin caused greater reductions or even abolition of L-glutamate induced firing. L-Glutamate firing of pyramidal tract cells was usually abolished by amounts of tetrodotoxin insufficient to prevent invasion of an antidromic spike.

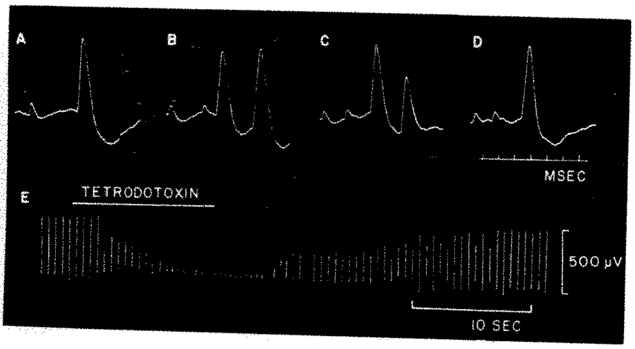

Fig. 1. Antidromic spikes, recorded from a cortical neurone, evoked by single (*A*) and paired stimuli (*B–D*) delivered to the ipsilateral medullary pyramidal tract. *E*, Antidromic spikes of same neurone recorded from a stationary cathode ray oscilloscope, using spike intensification, on slowly moving film. During application of tetrodotoxin (4 n.amp passed for period indicated by horizontal bar) antidromic invasion gradually failed. The residual response in *E* is the intensified stimulus artefact.

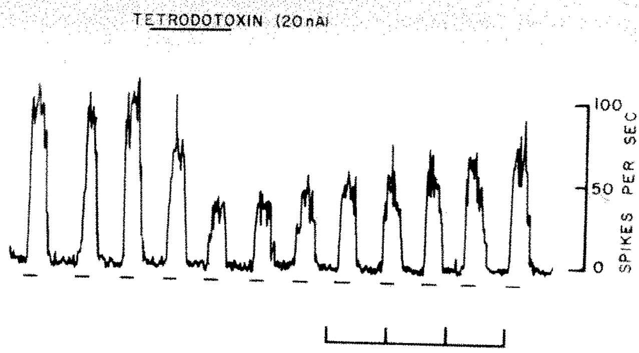

Fig. 2. Tetrodotoxin depression of the firing of a cortical neurone evoked by L-glutamate. Discharge frequency of the neurone was recorded by means of an electronic counter and ink recorder. Periods of L-glutamate and tetrodotoxin application are indicated by horizontal solid lines below and above traces, respectively.

These observations indicate that neurones of the mammalian central nervous system can be included in the group of tissues which have excitable processes sensitive to tetrodotoxin. The graded reduction in antidromic spike size shown in Fig. 1 suggests that the area of electrically excitable membrane available for spike generation was progressively reduced. Reductions in the magnitude of responses to L-glutamate and acetylcholine also indicate that excitability was reduced by tetrodotoxin, with the development of a higher threshold for spike initiation.

Small Molecular Weight Vitamin B_{12} Binders in Normal Human Serum

IN an investigation of vitamin B_{12} binders in human serum, three peptide-like binders were isolated by electrodialysis and by chromatography.

Radioactive B_{12} was obtained from Philips-Duphar, Holland, and had a specific activity of 30 mc./mg. To samples of fresh, pooled normal human serum, 300, 1,000 or 3,000 $\mu\mu$g of cobalt-57 labelled vitamin B_{12}/ml. of serum was added. The samples were dialysed at 40° C against twenty times their volume of distilled water for 5 days; the water was changed twice a day and toluene was added as preservative. Serum without additional labelled B_{12} was similarly treated. Euglobulins were precipitated during dialysis and the volume of dialysed serum was increased approximately three times as a result of osmotic pressure. The *p*H of the dialysed serum was 7·0.

Seventy ml. of dialysed samples, both precipitate and supernatant, was placed in 27/32 in. unmodified dialysis tubing (Thomas, Philadelphia) and the tubes were im-

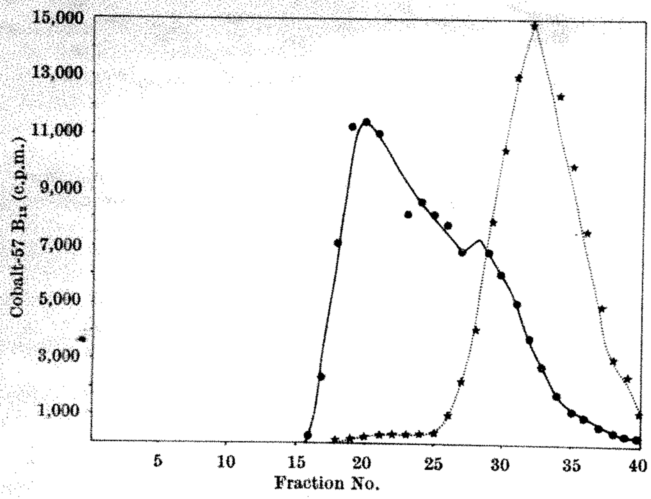

Fig. 1. Radioactive profile of concentrated electrodialysate on a 'Sephadex *G*-50' column, equilibrated and eluted with water. - - ★ - - represents the peak which was obtained when free radioactive B_{12} was chromatographed on the same column. Fractions of 2 ml. were collected and counted in a well-type scintillation counter.

mersed in 190 ml. of distilled water in a 'Pyrex' centrifuge bottle. A piece of platinum wire which was immersed along the entire length of the tubing served as anode, and another piece of wire which was placed in the surrounding water parallel to and 3 cm away from the anode served as the cathode. Electrodialysis of samples proceeded for 24 h at 150 V and 55–65 m.amp. Because experiments were performed in a cold room, temperature in the dialysis tubing did not exceed 8° C.

After completion of electrodialysis, the *p*H of the serum at 25° C was 4·5 while that of the electrodialysate was 7·0. The tubing content was homogenized by stirring and the vitamin B_{12} content of this suspension as well as that of the surrounding water (electrodialysate) was determined microbiologically using the *Euglena gracilis* method when radioactive B_{12} had not been added, or radiologically in a Baird atomic scintillation spectrometer when radioactive B_{12} had been added. The electrodialysate was concentrated to approximately 15 ml. and chromatographed on a 'Sephadex *G*-50' column (30 × 2·2 cm) using water as the developing solvent. The peak of radioactivity which was obtained from this column, and which coincided with the positive effluent of Folin's reagent[1], was further chromatographed on a 'Sephadex *G*-200' column (30 × 2·2 cm) by elution with water.

Samples of the concentrated electrodialysate were chromatographed on Whatman No. 4 paper in a butanol : acetic acid : water (65 : 10 : 25) solvent or in a butanol : acetic acid : water (60 : 20 : 20) solvent[2]. Paper chromatograms were dipped in 0·5 per cent ninhydrin in ethanol[2] to detect peptide-like substances or else were treated with periodic acid[3] to detect carbohydrates. Ninhydrin positive spots from paper chromatograms were eluted with 10 per cent acetic acid and were subsequently dried for further analysis.

A sample of the concentrated electrodialysate was hydrolysed in 6 normal hydrochloric acid for 22 h at 110° C (ref. 4) and dried products of hydrolysis were chromatographed on Whatman No. 1 paper in liquid phenol : water, 100 : 20 v/v, in the presence of 1 : 1 acetic acid[2]. Samples of naturally occurring amino-acids were developed parallel to the sample and dried chromatograms were dipped in 0·25 per cent ninhydrin in acetone.

In the process of electrodialysis a portion of vitamin B_{12} passed through the dialysis tubing and appeared in the electrodialysate, as shown in Table 1. Because samples were dialysed for 5 days before electrodialysis, free vitamin B_{12} cannot be expected to be present in the samples when dialysis is complete[5]. Vitamin B_{12} in the electrodialysate was therefore either dissociated before passing through dialysis tubing or else passed through it in the form of a complex with another substance.

Table 1. PRESENCE OF VITAMIN B_{12} OR RADIOACTIVITY OF COBALT-57 B_{12} IN DIALYSING TUBING AND ELECTRODIALYSATE

Radioactive B_{12} added to serum	Activity remaining in dialysis tubing Counts/ 5 min	Activity remaining in dialysis tubing $\mu\mu$g of vit B_{12}*	Activity in electrodialysate Counts/ 5 min	Activity in electrodialysate $\mu\mu$g of vit B_{12}*	Percentage of total activity appearing in electro-dialysate
None		6,095		1,740	22
300 $\mu\mu$g/ml.	953,800		171,000		15
1,000 $\mu\mu$g/ml.	3,704,000		621,500		15
3,000 $\mu\mu$g/ml.	10,625,000		3,131,000		23

* Microbiological assay by the *Euglena gracilis* method. These data are for 25 ml. of initial serum. The volume of dialysed serum used in each experiment was 70 ml. and the volume of the electrodialysate was 190 ml.

Because of the elution pattern which was obtained when the concentrated electrodialysate was chromatographed on the 'Sephadex *G*-50' column (Fig. 1), the vitamin B_{12} which was present in electrodialysate appeared in a bound form. The dotted line in Fig. 1 indicates the radioactive peak which was obtained when a sample of free vitamin B_{12} was chromatographed on the same column in the same experimental conditions. The combined total radioactivity (all samples under the solid line in Fig. 1) from the 'Sephadex *G*-50' column was rechromatographed on a 'Sephadex *G*-200' column, and two peaks of radioactivity, coinciding with the positive effluent, Folin's reagent, were obtained (Fig. 2). The first peak which corresponded to a complex of molecular weight between 10,000 and 20,000 as estimated by a comparison with elution patterns of ribonuclease, lysozyme and pepsin, represented a small part of the total radioactivity; the second peak corresponding to a complex of molecular weight 4,000 and 8,000 appeared ahead of the peak which was obtained from free vitamin B_{12} of approximately the same total radioactivity chromatographed on the same column in the same experimental conditions. Because of the presence of carbohydrates and aromatic amino-acids in the peptide-like substances, as will be discussed in the following paragraphs, these estimates of molecular weight are approximate[6].

The ninhydrin reagent revealed five positive zones on paper chromatograms the R_F values of which, in the two solvent systems employed, are given in Table 2. Zones 1, 2 and 4 contained vitamin B_{12} although partial dissociation of the vitamin B_{12} from the complexes occurred to the extent of 50–60 per cent, obviously caused by organic solvents. Eluted substance from zone 1 appeared in the position of the first radioactive peak when chromatographed on a 'Sephadex *G*-200' column; eluted substances from zones 2 and 4 appeared in the

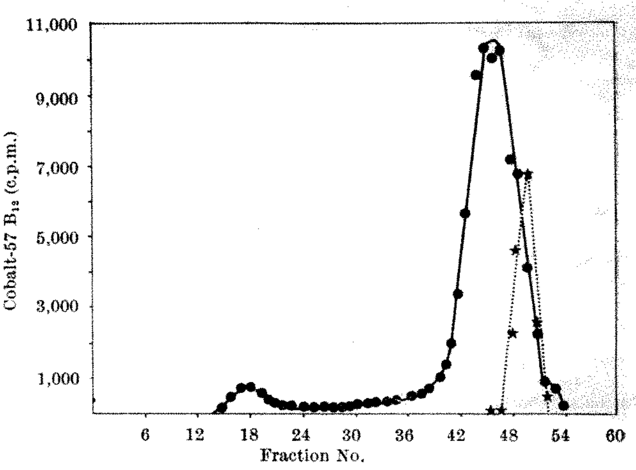

Fig. 2. Radioactive profile of peak from the 'Sephadex *G*-50' column re-chromatographed on a 'Sephadex *G*-200' column which was equilibrated and eluted with water. - - ★ - - represents free radioactive B_{12} chromatographed on the same column. Fractions of 2 ml. were collected and counted in a well-type scintillation counter.

Table 2. *RF* VALUES FOR FIVE NINHYDRIN POSITIVE ZONES

Zone	*RF* Butanol : acetic acid : water (65 : 10 : 25)	Butanol : acetic acid : water (60 : 20 : 20)
1	0·09	0·10
2	0·23	0·21
3	0·33	0·30
4	0·59	0·36
5	0·65	0·74

The solvent ran 45 cm on Whatman No. 4 paper.

position of the large radioactive peak from the 'Sephadex *G*-200' column (Fig. 2).

The indication that the vitamin B_{12} appeared to be in a bound form, in addition to the observation that complexes were ninhydrin positive, suggests the possible existence in normal serum of vitamin B_{12} binding peptides. Furthermore, ninhydrin positive zones gave positive reactions when treated with periodic acid, indicating the presence of carbohydrates. The nature of these carbohydrates is not yet known.

In the acid hydrolysate of the serum electrodialysate, cysteine, arginine, threonine, tyrosine, methionine, phenylalanine and leucine or isoleucine were tentatively identified. It is not yet known which amino-acids were present in each of the five ninhydrin positive zones appearing on paper chromatograms.

These results, although preliminary, suggest that vitamin B_{12} binding peptides are present in normal human serum. Because these peptides were not dialysable but could be electrodialysed, they were either products of protein decomposition occurring during the electrodialysis, or else were adsorbed onto the proteins by electrostatic forces. If the latter hypothesis is correct, complexes between proteins and peptides–vitamin B_{12} groups were electrostatic in nature and dissociated at the voltage used in the electrodialysis, while bonds between the peptides and vitamin B_{12} were not electrostatic.

We thank Miss Marian Dietrich for technical assistance and Miss Claire Mulzac for performing the microbiological assay. This work was supported by a grant from the US Public Health Service.

Histaminase Activities in the Plasma of Subhuman Primates and Man

MEASUREMENT of the concentrations of histamine in the plasma of rhesus (*Macaca mulatta*) and squirrel (*Saimiri sciureus*) monkeys after administration of the histamine-releasing agent, compound 48/80, or histamine has suggested that the rhesus monkey is more active in degrading histamine than the squirrel monkey[1]. Direct determination of histaminase activity in plasma showed that the rhesus monkey exhibits more activity of this enzyme than any other species tested, including man[2]. Squirrel monkeys and man were found to exhibit similar levels of this enzyme activity in the plasma[2]. In addition, squirrel monkeys, but not rhesus monkeys, responded to compound 48/80 by exhibiting an elevation of circulatory histamine[1], as does man[3].

The importance of subhuman primates as models of man in biological research led us to survey other simian species to find whether high activities of plasma histaminase are unique to rhesus monkeys. We obtained from this institute heparinized plasma from additional squirrel and rhesus monkeys and from stump-tailed (*M. speciosa*) and pig-tailed (*M. nemestrina*) macaques. Plasma obtained from outside laboratories was from greater galago (*Galago crassicaudatus panganiensis*), lesser galago (*G. senegalensis braccatus*), cotton-topped marmoset (*Saguinus oedipus*), night monkey (*Aotus trivirgatus*), talapoin (*Miopithecus talapoin*), anubis baboon (*Papio anubis*), yellow baboon (*P. cynocephalus*), western baboon (*P. papio*), gibbon (*Hylobates lar* and *H. pileatus*), chimpanzee (*Pan troglodytes*) and gorilla (*Gorilla gorilla*). Plasma was also obtained from volunteers from our laboratory. Frozen heparinized plasma was shipped from outside sources and assayed within 2 weeks of the time of bleeding. Our previous studies with plasma from squirrel or rhesus monkeys or from man have indicated that storage in the frozen state for up to 4 weeks caused no change in histaminase activity[2]. Furthermore, redetermination of histaminase activities in individual squirrel or rhesus monkeys or in human subjects up to 6 months after the initial determination showed that these activities were relatively stable individual characteristics. Protein concentrations in the plasma were determined[4] to allow expression of histaminase activities in each gram of plasma protein. Histaminase activities were measured as described before[2]. Only physical restraint was employed when most of the animals were bled. Exceptions were the first group of chimpanzees listed in Table 1, which received phencyclidine hydrochloride (1·0 mg/kg) intramuscularly, and the gorillas, which received the same anaesthetic agent intramuscularly in a dose of 1·5 mg/kg. In addition, all but two of the gorillas of Table 1 received atropine sulphate (0·01 mg/kg). Phencyclidine hydrochloride in a concentration of 1·6 μg/ml. did not inhibit the colour detection system for measuring histaminase activity in the absence of plasma with added hydrogen peroxide. The same concentration of added phencyclidine hydrochloride did not inhibit the activity of histaminase in the plasma from a rhesus monkey. The activity of histaminase in the plasma of an anaesthetized rhesus monkey 15 min after intramuscular injection of phencyclidine hydrochloride (1·1 mg/kg) was 92 per cent of the activity measured before the drug was given.

Table 1 summarizes the results obtained in the animals surveyed. The plasma protein concentrations were within

Table 1. MEAN BODY WEIGHT, PLASMA PROTEIN CONCENTRATION AND PLASMA HISTAMINASE ACTIVITY OF THE SPECIES STUDIED (± *SD*)

Species	Body weight (kg)	Plasma protein (g %)	Histaminase activity*
Prosimian			
Greater galago, 5♂, 5♀	1·2 ± 0·1	6·2 ± 0·5	232 ± 93
Lesser galago, 5♂, 4♀	0·29 ± 0·05	6·2 ± 0·3	141 ± 38

* mμmole/l. of histamine oxidized/min/g of plasma protein.

normal limits where such limits are known. No consistent sex differences were found in plasma histaminase activities, and so all subjects of one species were treated as a single group. The group of gibbons comprised two of the species *H. pileatus* and eight of *H. lar*; they were combined because no marked differences between the two species were noted. In addition, in all species studied except the gorilla (discussed later), no association between body weight and plasma level of histaminase activity was found. Although some groups contained immature animals, no separation of animals by body weight was therefore made in reporting results. Two groups of chimpanzees from different sources were studied. The first group, which had received the anaesthetic phencyclidine hydrochloride, showed slightly lower activities than the second group, which received no drugs. In addition, there was a small difference in the concentration of plasma protein between the two groups of chimpanzees. The biological significance of these differences in such a small number of animals is, however, questionable; the mean levels for all the chimpanzees studied are therefore presented.

It is immediately apparent from Table 1 that the prosimian and the Old World species exhibited relatively high levels of histaminase activities compared with the three New World species and man. Thus the rhesus monkey is not unique in possessing high plasma histaminase activity. On the contrary, the current observations suggest that man and New World species are unusual among the primates in this regard. In an earlier survey of common laboratory species[2], mice and rats were found to have essentially no histaminase activity in the plasma; in guinea-pigs and dogs, the activity was similar to that in man and squirrel monkeys; in cats and rabbits, it was two to three times higher than in man, but only about one-third of that found in rhesus monkeys.

Although fourteen gorillas were surveyed, results for only nine are included in Table 1. The remaining five (three male and two female) showed no histaminase activity in the plasma; all had received phencyclidine hydrochloride, but only one had atropine sulphate. Their mean plasma protein concentration was 5·7 ± 0·4 g per cent, similar to that of the nine reported in Table 1, but their mean body weight was 19 ± 2 kg, approximately half that of the group showing plasma histaminase activity. It is not clear why this group of five gorillas failed to exhibit plasma histaminase activity. In no other primate species were subjects found with no such activity.

Why man exhibits such a dichotomy between plasma histaminase activities and his phylogenetic relationship with the subhuman primates is puzzling. More detailed studies on blood specificities[5], quantitative immunochemical correspondence of albumins[6,7], electrophoretic patterns or erythrocytic esterases[8], and the molecular structure of myoglobin[9] of subhuman primates and man have provided clear support for the phylogenetic classification, which is based on anatomical and organismal comparisons. Nevertheless, studies of the primary structure of primate haemoglobins[10] suggest that not all biological molecules or activities should be expected to follow absolutely the phylogenetic relationships. Of particular interest in this regard is the recent report[11] that two prosimian species, the tree shrew (*Tupaia glis*) and the slow loris (*Nycticebus coucang*), can synthesize ascorbic acid, whereas no Old or New World subhuman primate studied so far has shown this ability.

The current results with plasma histaminase activities suggest that for investigations of drugs or toxic agents expected to influence the physiological or pharmacological role of histamine in man, New World subhuman primates may be better test animals than Old World ones.

This work was supported in part by a contract from the US Army, Edgewood Arsenal, Maryland. We thank Drs S. Crane, L. Otis and J. Scholler for allowing us to obtain blood samples from their animals. We also thank Drs R. W. Cooper, R. L. Hummer, H. Vagtborg, A. J. Riopelle, C. W. Hill, D. C. Van Riper, W. C. Wisecup and C. M. Rogers for plasma.

Fine Structure of the Sensory Endings in the Vomero-nasal Organ of the Slow-worm *Anguis fragilis*

THE structure of the sensory endings of the vomero-nasal organ of vertebrates (Jacobson's organ) has been the subject of some controversy in past years[1-3]. Although the receptor cells seem to resemble closely those of the olfactory epithelium, the presence of cilia on their free ends is arguable. The problem has not yet been investigated by electron microscopy, and it is of interest to report the fine structure of these endings in a reptile, *Anguis fragilis*, where the vomero-nasal organ is particularly well developed.

Sections show that the receptor endings in this animal are completely lacking in cilia, but are provided with numerous microvilli (Fig. 1). The microvilli are long, and those of neighbouring receptors intermingle to form a complex meshwork above the epithelial surface. When thick sections of the same material are viewed by light

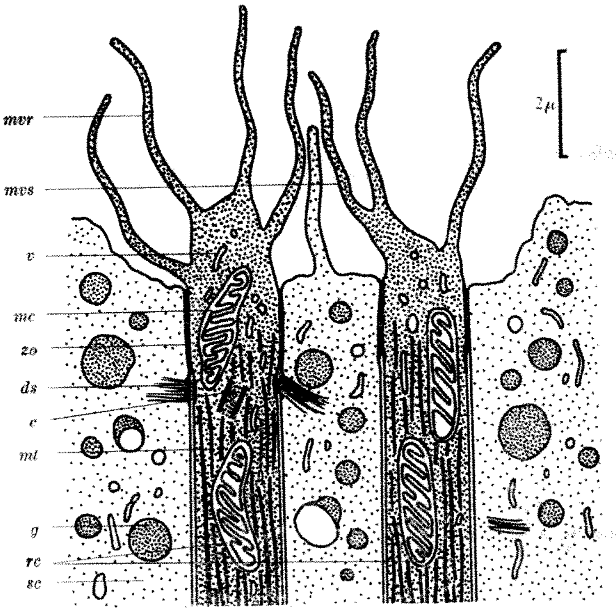

Fig. 1. Diagram of surface of vomero-nasal organ in vertical section, showing two receptor endings with microvilli. *c*, Centriole; *ds*, desmosome; *g*, secretory granule; *mc*, mitochondrion; *mt*, microtubule; *mvr*, microvillus of receptor cell; *mvs*, microvillus of supporting cell; *rc*, receptor cell dendrite; *sc*, supporting cell; *v*, vesicle; *zo*, zonula occludens.

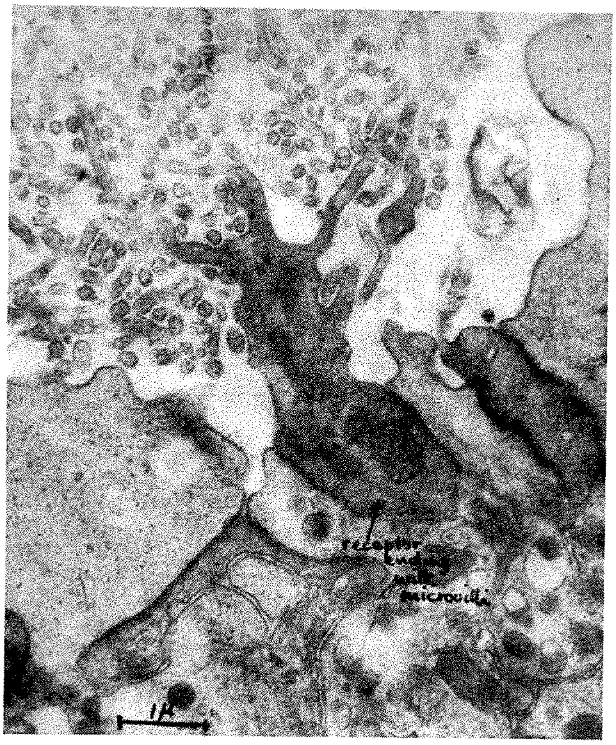

Fig. 2. Micrograph of oblique section through the receptor tip of the vomero-nasal (Jacobson's) organ.

microscopy this meshwork presents an indeterminate appearance suggestive of poorly fixed cilia, an appearance which may have been the cause of the disagreements in the literature.

In other respects the endings resemble those of vertebrate olfactory receptors, the mitochondria, microtubules, and small vesicles being constant features of the cytoplasm. The supporting cells which surround the receptors bear occasional microvilli and contain numerous densely staining secretory granules.

Other chemoreceptors bearing microvilli have been described, examples being the olfactory receptors in birds[4,5] where microvilli are found in association with cilia, and one type of olfactory receptor in a species of teleost fish[6]. These findings emphasize that cilia are not indispensable to the chemosensory process. It remains to be seen whether or not other vertebrates have endings on their vomero-nasal receptors similar to those of *Anguis*.

Striated Muscle in the Cortex of Foetal Guinea-pig Thymus

Striated muscle cells, referred to as "myoid" cells, have been described by light microscopists in the medulla of the thymus of a variety of vertebrates[1]. "Myoid" cells are rare, however, and most reports of the ultrastructure of the mammalian thymus make no mention of them. Van de Velde and Friedman identified "myoid" cells in a variety of mammals[2,3] but did not show them in the normal mammalian thymus. They and others, however, showed electron micrographs of striated muscle in non-mammalian thymus and in a lymphoepithelial thymoma in a patient with myasthenia gravis[3-5].

During a light and electron microscopic study of osmium-fixed thymus from numerous foetal and post-natal guinea-pigs, only one "myoid" cell was seen. Ultrastructurally, this cell (Fig. 1) showed the typical cross striated appearance of skeletal muscle and seemed to be contracted[6]. There were accumulations of glycogen just inside the cell membrane and also scattered in between the myofilaments. No nuclei were visible in the profile studied, nor was there any evidence of nerves in the vicinity of this cell. A further unusual feature was the location of this cell in the cortex. A study with the light microscope of an adjacent "thick" section (1μ) stained with toluidine blue confirmed the cortical position of the cell (Fig. 2).

The ultrastructural appearance of the cell described and of "myoid" cells illustrated by other authors[3-5] is typical of striated muscle and the term "myoid" cell may there-

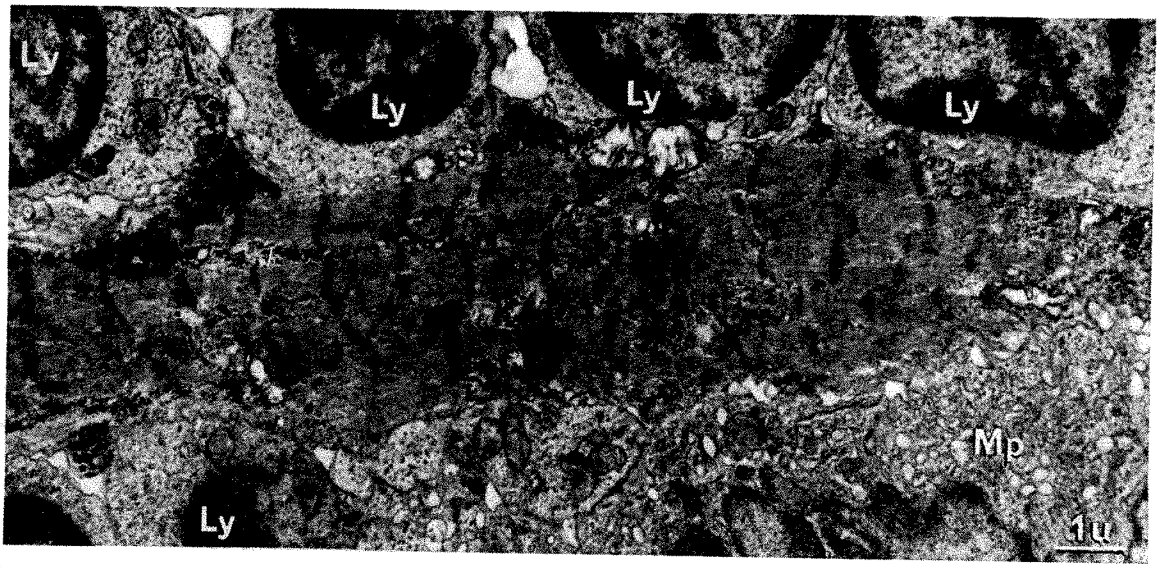

Fig. 1. Electron micrograph of a thymic striated muscle cell. The cell is surrounded by small lymphoid cells (*Ly*) and by a macrophage (*Mp*). Osmium, uranyl acetate, lead citrate. (× *c*. 10,500.)

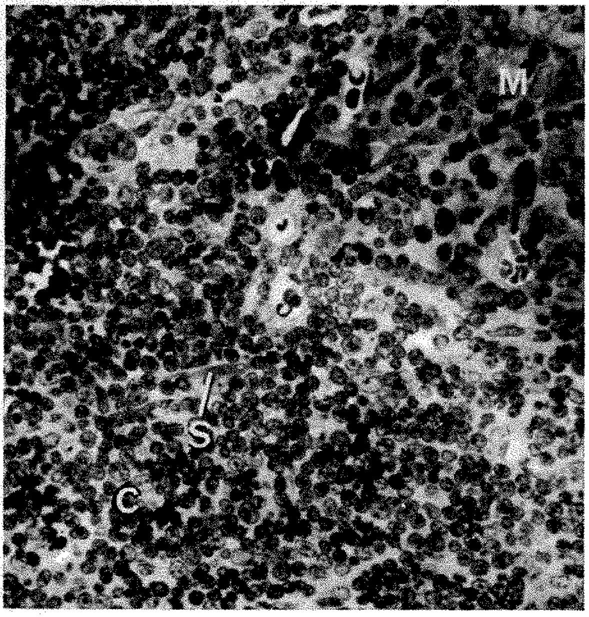

Fig. 2. Light micrograph of a "thick" section showing part of the thymus containing the striated muscle cell (*S*) illustrated in Fig. 1. Note the distinction between cortex (*C*) and medulla (*M*) and the striated muscle cell in the cortex close to the cortico-medullary junction. Osmium, embedded in araldite, toluidine blue. (× *c*. 300.)

fore be redundant. It has been demonstrated by immunofluorescence that a common antigen is shared by striated muscle and by some "thymic epithelial cells"[7], and it has been suggested that the fluorescent thymic cells may be "atrophic, rounded up, striated muscle cells which had lost their morphological identifying features"[4]. In this study, however, no cells which could be classified as being intermediate between striated muscle and thymic epithelium were seen with the electron microscope, and all epithelial cells could be recognized as such because they contained irregularly arranged bands of tonofibrils and were joined to one another by desmosomes. No evidence of persisting cross striation was seen in any of the epithelial cells.

It has also been suggested that thymic striated muscle may act as a local source of antigen for the "self-recognition" of skeletal muscle[8]. In view of the uncommon occurrence of thymic striated muscle, such a function may be difficult to sustain. It seems more likely, as Van de Velde *et al.*[3] suggested, that the skeletal muscle cells are incorporated into the thymus as myoblasts, possibly as an accidental event during embryonic development of the thymus.

I thank Professor G. C. Schofield for his help in the preparation of this manuscript.

Radioimmunoassay of Angiotensin

HABER *et al.*[1] showed that antibodies elicited in rabbits by copolymers of angiotensin with poly-L-lysine can be used for radioimmunoassay of angiotensin. The following are details and some results of the method we have developed. Comparing the binding affinity of three different rabbit antisera to Val^5-angiotensin II amide ('Hypertensin', Ciba) and three analogues, we found that these antisera do not quantitatively behave identically. This fact has important consequences for the standardization of immunoassays of angiotensin in human plasma as long as human angiotensin is not available as a chemically pure substance. (Val^5-angiotensin has the amino-acid sequence of bovine angiotensin, while Ileu^5-angiotensin represents the structure of horse, hog and possibly human angiotensin.)

Vallotton *et al.*[2] found no differences in binding affinity to Val^5-angiotensin II amide and Ileu^5-angiotensin II amide with a similar method; in contrast, our antisera distinguished between Val^5-angiotensin II amide and Ileu^5-angiotensin II amide. Dietrich[3] also found this difference with another technique. (The difference between Ileu^5-angiotensin II and Ileu^5-angiotensin II amide seems to be of no importance in this respect, because the amide group has scarcely any immunological influence (Table 1).)

If human angiotensin is Ileu^5-angiotensin, the use of different antisera in immunoassays of human angiotensin may lead to different results, when Val^5-angiotensin II amide is used as a standard.

Antibodies were produced by immunizing rabbits with copolymers of Asp(NH$_2$)^1-Val^5-angiotensin II ('Hypertensin', Ciba) and poly-L-lysine coupled with 1-ethyl-3-(3-dimethyl-aminopropyl) carbodiimide hydrochloride (ethyl CDI) according to the method of Goodfriend *et al.*[4]. About 1 mg of the product was suspended in 0·8 ml. of a 0·9 per cent sodium chloride solution and emulsified with 0·2 ml. of complete Freund's adjuvant. Each rabbit was injected intramuscularly with 1·0 ml. After three injections at monthly intervals, three out of ten animals yielded sufficient antibody titres for our experiments.

^{125}I-Asp(NH$_2$)^1–Val^5-angiotensin II was prepared according to the chloramine *T* method of Hunter and Greenwood[5], using 0·5 mc. Na^{125}I for 5 μg angiotensin. The free iodide was separated from ^{125}I-angiotensin by means of an 'Amberlite *IRC* 50' column in H$^+$ cycle (0·5 × 0·5 cm) and removed with 0·2 molar ammonium acetate, *p*H 6·5. The labelled angiotensin was eluted with 0·05 normal ammonium hydroxide; it was then adjusted to *p*H 8·5 with *tris*-hydrochloric acid buffer and stored at −20° C. To diminish radiation damage and adsorption to the glassware, human serum albumin (HSA) was added to give a final concentration of 250 mg/100 ml. The labelled material had a specific activity of 60–70 mμc./ng. Antiserum added in excess bound 90 per cent of the labelled angiotensin. Various samples of labelled angiotensin were stored at a different *p*H (4·0–9·0) for 1 month at −20° C. The *p*H had no detectable influence on the quality of the labelled material.

Standard solutions of angiotensin containing 2·5, 5, 10, 20 or 40 ng of Asp(NH$_2$)^1–Val^5-angiotensin II in 1·5 ml. were prepared by serial dilutions with a mixture of two volumes of 0·3 molar ammonium hydroxide and one volume of 1·4 molar *tris* buffer brought to *p*H 8 with hydrochloric acid (HAS added). This mixture was chosen

Table 1. RATIO (± *S.D.*) OF EQUIMOLAR AMOUNTS NECESSARY TO REDUCE THE INITIAL BINDING TO 50 PER CENT

Compound	Amino-acid sequence	Ratio Antiserum No. 6019	 7046	 7051
A	Asp(NH$_2$)–Arg–Val–Tyr–Val–His–Pro–Phe	1	1	1
B	Asp–Arg–Val–Tyr–Val–His–Pro–Phe	1·08 ± 0·04	1·1	1·1
C	Asp(NH$_2$)–Arg–Val–Tyr–Ileu–His–Pro–Phe	1·43 ± 0·13	1·9	2·5
D	Arg–Val–Tyr–Ileu–His–Pro–Phe	1·80 ± 0·15	2·3	4·2

for two reasons: (1) the binding of the antigen and the antibody is at an optimum between *p*H 7·5–9·5; (2) ammoniacal eluates containing angiotensin from cation resin columns (often used to isolate angiotensin from human plasma) can be tested directly after mixing with a *tris* buffer. In this way evaporation to dryness and subsequent redissolving of the eluate[6] are not necessary. The antiserum was diluted with normal rabbit serum (as a source of carrier gamma globulins) to an antibody concentration which provided a 50–60 per cent binding of 0·025 μc. ^{125}I-angiotensin and di-Na-EDTA were added to a final concentration of 0·06 molar to inhibit aminopeptidase activity.

A mixture of ammonium hydroxide and *tris* buffer (1·5 ml.), containing the angiotensin, was mixed in a glass tube with 0·05 ml. of the ^{125}I-angiotensin solution (about 0·025 μc.) and incubated with 0·5 ml. of diluted antiserum. After incubation for 1 h at room temperature, 2·05 ml. of saturated ammonium sulphate (4° C, *p*H 8) was added. After standing for 4 h at 4° C, the mixture was centrifuged (at 4° C) until the supernatant was clear. The supernatant was discarded. The precipitate was washed once with a half-saturated ammonium sulphate solution (4° C, *p*H 8) and dissolved at room temperature in 2 ml. of phosphate buffered saline (*p*H 7·4). The radioactivity of the sample was then measured.

The results were expressed as a percentage of radioactivity bound to antigen, "100 per cent" representing the initial binding (no unlabelled angiotensin added). Equimolar amounts of Asp^1-Val^5-angiotensin II (compound *B*), Asp(NH$_2$)^1-Ileu^5-angiotensin II (compound *C*) and des-Asp^1-Ileu^5-angiotensin II (heptapeptide 2-8, compound *D*) were compared with Asp(NH$_2$)^1-Val^5-angiotensin II (compound *A*), in respect to the binding affinity.

In Fig. 1 the mean values of nine different series of determinations (each series in triplicate), obtained with an antiserum produced by one rabbit (No. 6019), are shown. The standard deviation of the individual determination was ±7 per cent.

For each series the ratio of equimolar amounts of compound *B*, *C* and *D* relative to *A*, necessary to reduce the initial binding to 50 per cent, was calculated. The mean values are given in Table 1.

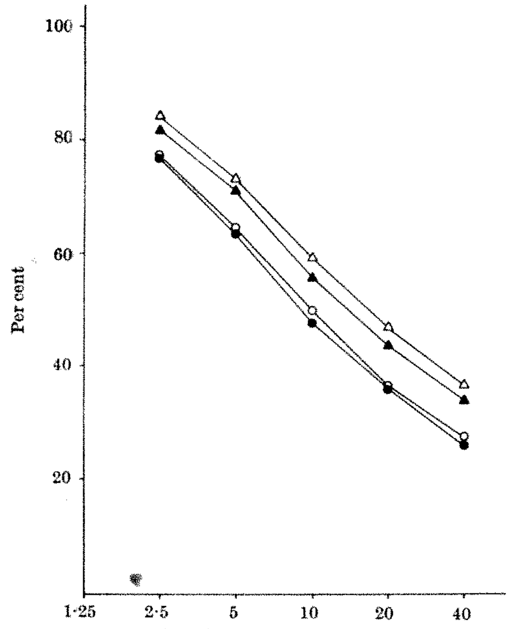

Fig. 1. Displacement of radioactivity from the antibodies by increasing amounts of Asp(NH$_2$)^1-Val^5-angiotensin II (compound *A*, plotted in ng per tube) compared with equimolar amounts of compounds *B*, *C* and *D*. 100 per cent represents the initial binding. ●, Asp(NH$_2$)^1-Val^5-angiotensin II; ○, Asp^1-Val^5-angiotensin II; ▲, Asp(NH$_2$)^1-Ileu^5-angiotensin II; △, des-Asp^1-Ileu^5-angiotensin II.

The differences between the various compounds cannot be explained by impurity of the substances because the Val^5-angiotensin II amide antibodies produced by three different rabbits (Nos. 6019, 7046 and 7051) possess different immunological affinities to compounds *B*, *C* and *D*.

We thank Dr F. Gross, Ciba, Basle, for his gifts of compounds *A* and *B* and Miss W. Kloosterziel and R. van Aalst for technical assistance. Professor E. Havinga, University of Leiden, provided compounds *C* and *D*.

Axoplasmic Transport of ^{14}C-Noradrenaline and Protein in Splenic Nerves

MOST of the noradrenaline in postganglionic sympathetic neurones is bound within amine granules concentrated in the axon terminals[1]. These structures, which contain protein, are involved in the synthesis, storage and release of noradrenaline[2]. When a constriction is placed on the nerve trunk, noradrenaline accumulates proximal to it. This has been ascribed to the arrested distal transport of the granules from their site of manufacture in the cell body[3], a view which is supported by electron microscope evidence of a corresponding accumulation of granular vesicles[4]. Their flow rate in cat sympathetic nerves of 10 mm/h, however, derived from the rate of noradrenaline accumulation[3], is about 200 times that obtained for protein movement in somatic nerves (1 to 5 mm/day)[5]. Because the calculation assumes that no noradrenaline is synthesized, lost to or taken up from the circulation in the movement of the storage granules down the axon and at the site of constriction, an alternative method, labelling both noradrenaline and protein with isotopes, was used on the cat splenic nerves.

At laparotomy under ether anaesthesia, either ^{14}C-noradrenaline (5–10 μc.; 17·2 mc./mmole) or ^{14}C-leucine (5 μc.; 305 mc./mmole) was injected into the coeliac ganglion by multiple puncture of the capsule through a silicone grease seal, using a microsyringe with an electrolytically polished tip of 200μ. The cats were pretreated with iproniazid (50 mg/kg, intraperitoneally), and the preganglionic splanchnic nerves were cut, in order to minimize losses caused by metabolism and release, respectively. Two fine silk constrictions were placed 1 cm apart on a branch of the splenic nerves about 5 cm from the ganglion. After 6–24 h, the splenic nerves were stripped off the artery, cut into consecutive 5 to 10 mm pieces and homogenized in perchloric acid containing ethylenediamine tetra-acetic acid. Extracts containing catecholamines were counted for total radioactivity in aqueous scintillator[6]. Paper chromatography[7] showed that most of the radioactivity was present as noradrenaline and, to a lesser extent, normetanephrine. Proteins were washed with lipid solvents and dissolved in formamide. A sample was estimated for total protein, and the rest counted for incorporation of ^{14}C-leucine.

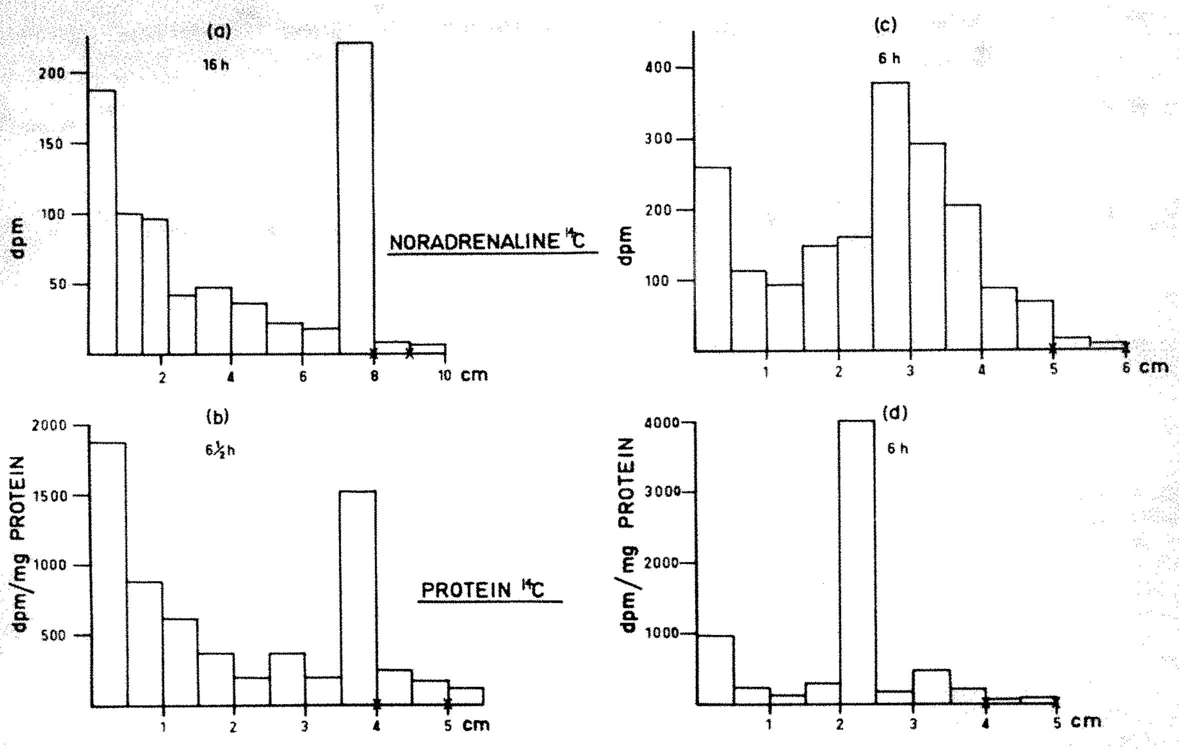

Fig. 1. Transport of ^{14}C-noradrenaline (*a* and *c*) and ^{14}C-protein (*b* and *d*) in cat splenic nerves. Abscissa: distance from coeliac ganglion. ×, Site of constriction. The distances shown in these four experiments are the minimum as measured *in situ*, and are subject to an error of up to 5 mm.

There was an accumulation of both labelled noradrenaline and protein just proximal to the upper nerve constriction but not the lower (Fig. 1 (*a*) and (*b*)). This indicates that a neural transport mechanism rather than uptake from the circulation was responsible for the accumulation.

Left for longer periods, the portion of spleen supplied by the untied branch of the nerve contained three to four times as much ^{14}C-noradrenaline as that supplied by the constricted branch, showing that labelled noradrenaline had reached the nerve terminals in the spleen by axonal transport as well as through the circulation. With shorter periods of 6–8 h, it was possible to locate peaks of both ^{14}C-noradrenaline and protein before they reached the constriction (Fig. 1 (*c*) and (*d*)).

The flow rate of approximately 5 mm/h obtained from these peaks is half that estimated previously for cat sympathetic nerves[3], but is considerably greater than any yet demonstrated for protein. If the noradrenaline is transported in granular vesicles, there may be two protein transport rates operating in the axon as observed in goldfish optic nerves[8]; perhaps a slow rate for structural proteins such as neuro-filaments, which the time scale of our experiments would not resolve, and a much faster one for soluble proteins and cytoplasmic particles like synaptic vesicles.

Fine Structure of Nerve Fibres in Smooth Muscle of the Vas Deferens in Normal and Reserpinized Rats

IT is evident from Thaemert's[1] review that the intra-axonal granular vesicles are generally considered to be the site of storage of catecholamines in autonomic nerves. It has also been shown[2–7] that reserpine has a depleting effect on these amine stores in both peripheral and central nervous systems. No quantitative data on the effect of reserpine on various types of granular vesicles have been published, so a study of the effect of this drug on the nerve fibres of the vas deferens of the rat was undertaken.

Twelve male albino rats (200–250 g) were used in this work. Four were untreated controls, four received intraperitoneal reserpine (10 mg/kg) and were killed 6 h later, and four received three daily intraperitoneal injections of the same amount of reserpine and were killed 6 h after the last dose. The animals were killed by a blow on the head. Small pieces of vas deferens were quickly removed, fixed in buffered osmium tetroxide, dehydrated in acetone and embedded in 'Araldite'. Ultrathin sections were stained with lead citrate and examined in a Siemens Elmiskop 1*B* electron microscope.

The general organization of the smooth muscle cells and of the spatial relationships between nerve fibres and muscle cells in the rat vas deferens was found to be similar to that reported by Richardson[8]. The muscle is arranged in an outer longitudinal and an inner circular layer. Passing between the muscle layers are small groups of axons enclosed by Schwann cell cytoplasm and surrounded by a thin investment of connective tissue. These nerve bundles in turn branch into smaller groups, or even single axons, which run in the narrow spaces between smooth muscle cells.

There was a striking variation in the density of innervation of the rat vas deferens between the prostatic and epididymal ends (Table 1), the prostatic end having the most nerve fibres. The inner circular layer was relatively more densely innervated towards the epididymal end.

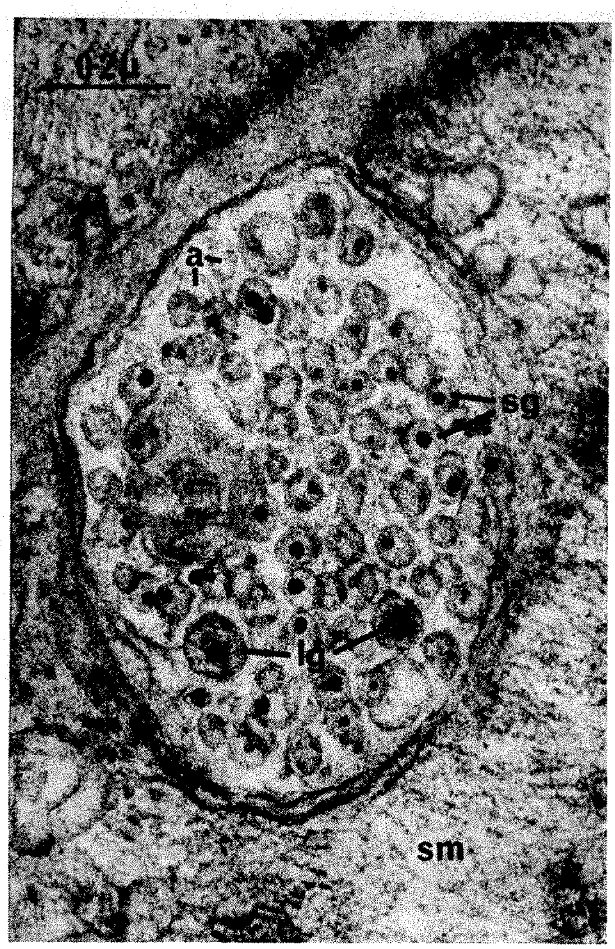

Fig. 1. An axon from a normal rat vas deferens, adjacent to smooth muscle cell (*sm*): agranular vesicles (*a*), small granular vesicles (*sg*) and an occasional large granular vesicle (*lg*). (× *c*. 85,000.)

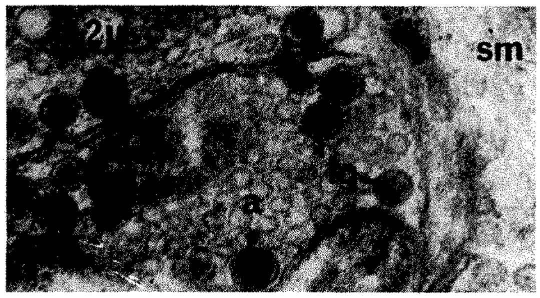

Fig. 2. Two axons from a reserpinized rat containing several large granular vesicles and agranular vesicles. (× *c*. 60,000.)

The axons contained the usual organelles: small membrane bounded vesicles, neurofilaments, neurotubules and mitochondria.

The neurofilaments have a diameter of about 60 Å and course through the axoplasm in all directions. They sometimes seem to interconnect vesicles and mitochondria by an extensive branching network (Fig. 1). In some axons neurotubules are especially numerous and often branch. They measure 200–250 Å in external diameter and contain a less electron dense core. They are usually orientated in the direction of the long axis of the nerve fibre. At intervals along their length there are small central aggregations of material of greater electron density. Small vesicular elements were frequently seen, which could be neurotubules cut in cross-section. The vesicles are of two types (Fig. 2). First, there are agranular vesicles enclosing a homogeneous material of low electron density. These are of fairly uniform size, 450–600 Å in diameter, with an occasional large vesicle 1000–2000 Å in diameter. Second, there are granular vesicles which fall into two classes. The first is a small vesicle (400–600 Å in diameter) containing a small dense inclusion (150–200 Å) which may be oval, rod-shaped or in the form of a doublet. The second is a large vesicle (800–1200 Å in diameter) which contains a spherical granule of moderate electron density (550–850 Å). All types of vesicles may be present in the same axon, but few axons exclusively contain agranular vesicles.

Table 1. AVERAGE NUMBER OF AXONS IN EACH OF SIX 75μ GRID SQUARES

	Prostatic end	Middle third	Epididymal end
Inner circular layer	79	63	33
Outer longitudinal layer	73	58	20

Fig. 3 shows vesicle population counts of 250 axons in normal animals and 250 axons in animals reserpinized for 6 h. In both groups the axons were selected at random from electron micrographs of the outer longitudinal layer of the middle third of the vas deferens. In normal rats there were approximately equal numbers of granular and agranular vesicles; 96 per cent of the granular vesicles were of the small, dense cored variety and 4 per cent were large with less dense centres.

Single or repeated doses of reserpine caused a marked reduction in the numbers of granular vesicles in nerve endings. This depleting effect was confined to the small granular vesicles (Fig. 4). The small granular vesicles were reduced from 48 per cent of the total in normal rats to 15 per cent of the total in the treated animals. The population of the large granular vesicles increased. The number of agranular vesicles was greatly increased ($P < 0·001$), but the total number of vesicles was not altered significantly.

It seems that the chief storage site of noradrenaline is in the small granular vesicles, but some of these storage sites seemed to be insensitive to depletion by reserpine in the doses given. The increase in agranular vesicles repre-

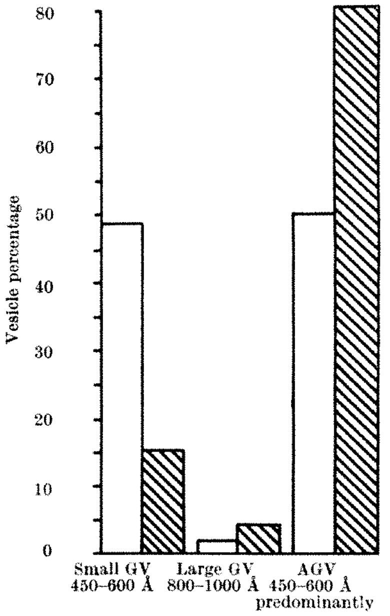

Fig. 3. The percentage of small granular vesicles, large granular vesicles and agranular vesicles in normal animals (white columns), and in rats reserpinized for 6 h (hatched columns). The absolute numbers of vesicles counted in each 250 axon series were 10,963 in normal animals and 11,305 in treated animals.

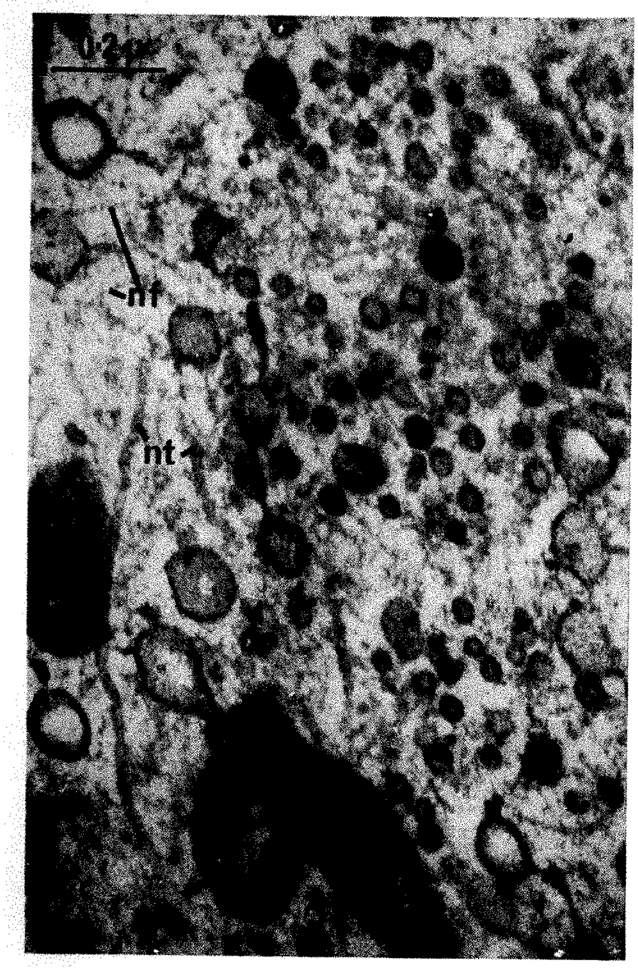

Fig. 4. An axon from a reserpinized animal. Neurotubules (*nt*) and neurofilaments (*nf*), which interconnect other organelles, are contained in the axoplasm. (× *c.* 75,000.)

sents vesicles of the same size which were granular before reserpinization. The larger granular vesicles, rather than being depleted by reserpine, increased in number.

In view of these findings, and those of Richardson[9] and Grillo[10], who showed, respectively, that the cholinergic axons of the dilator pupillae muscle and the superior cervical ganglion contained large granular vesicles, it seems possible that these larger granular vesicles in the vas deferens are a storage site for acetylcholine. The presence of both acetylcholine and noradrenaline within the same axons would lend support to the hypothesis of Burn and Rand[11] that both noradrenaline and acetylcholine are present in the same nerve fibre.

But the large granular vesicles may contain neither acetylcholine nor noradrenaline. It is possible that the inclusion is an unidentified neurotransmitter or its precursor. Alternatively, a different form of binding of a known neurotransmitter may be involved.

It is likely that the neurotubules, present in large numbers and many of which branch, are concerned with the function of intra-axonal transport. The theory of the distal flow of axoplasm is well substantiated and it is possible that neurotransmitter substances are manufactured at least partly in the cell body and transported to the periphery by means of the neurotubules. Silva[12] reported the presence of irregular dilatations along the course of intra-axonal neurotubules and suggested that these dilatations may represent a stage in the formation of the vesicles.

The observed variation in the density of innervation along the length of the vas deferens of the rat shows that extra care is necessary in interpreting quantitative results obtained by electron microscopy.

Types of Motor Units in the Skeletal Muscle of *Xenopus laevis*

INVESTIGATION of the histochemical and contractile characteristics of muscle fibres in hind limb muscles of *Xenopus laevis* and *Bufo viridis* has shown that the fast group of muscle fibres can be subdivided[1]. Some fast fibres, usually those of largest diameter, are low in oxidative enzymes and have few fat droplets. On direct electrical stimulation the contractile mechanism in these fibres rapidly fatigues. The second group of fast fibres consists of cells of smaller diameter showing a high activity of oxidative enzymes and containing many fat droplets. These fibres maintain a contracted state for prolonged periods if repeatedly stimulated. Electron microscope observations (unpublished results of R. S. Smith and S. Page) confirm the histochemical findings in that the two types of fibres contain differing numbers of mitochondria and fat droplets, and also demonstrate a higher concentration of glycogen in the latter group of fast fibres.

Slow muscle fibres isolated from *Xenopus laevis* have been found to be histochemically[1], functionally[1,2] and structurally (unpublished results of R. S. Smith and S. Page) distinct from the two types of fast fibres. In our previous study[1] of the group of slow fibres, we were unable to find evidence that the group could be subdivided, although Shamarina[3] has presented evidence which indicates that a subdivision does exist in the frog.

The present investigation was begun with the following intentions: (1) to determine whether fast motor units are homogenous; (2) to attempt to detect sub-groups within the slow fibres; and (3) to explore the relationship between the type of motor unit and the diameter of the motor nerve.

The iliofibularis muscle of *Xenopus laevis* was used throughout. As in other members of the Anura[4], the iliofibularis muscle of *Xenopus* is zoned[1]. The large and fatigable fast fibres occupy the outer parts of the muscle, while the less fatigable fast fibres and slow fibres are in the centre of the muscle. This organization assists in assessing the position and thus the likelihood of homogeneity of fast motor units.

The nerve–muscle preparation was kept in Ringer's solution at 20°–23° C in a 'Perspex' recording chamber of the type described before[1]. A single nerve fibre was dissected from the nerve trunk and stimulated electrically with rectangular pulses of 1 msec duration and amplitude about 2 dB above threshold. The contraction of the motor unit was recorded isometrically by a strain gauge attached to one tendon of the muscle, the other tendon being fixed. The strain gauge output was displayed on a strip chart

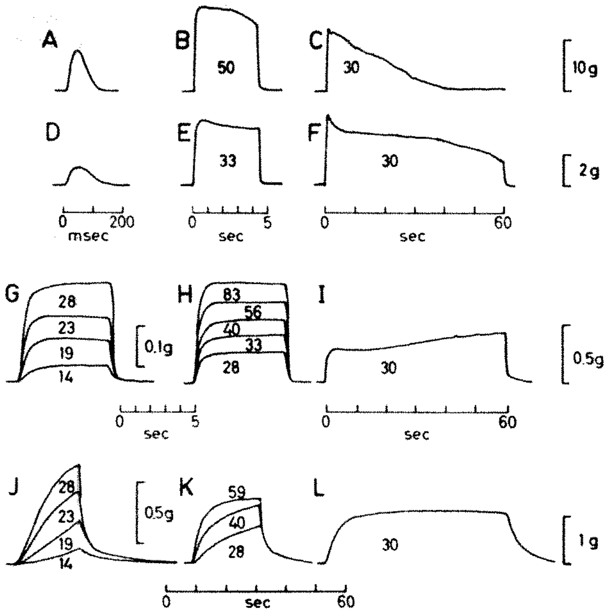

Fig. 1. Mechanical activity of single motor units in the iliofibularis muscle after their motor nerves had been stimulated. The number on each trace indicates the rate of stimulation in stimuli/sec. Traces *A* and *D* are twitch responses to single stimuli. *A*, *B* and *C*: responses of a fast motor unit in the peripheral part of the muscle. *D*, *E* and *F*: responses of a fast motor unit in the centre of the muscle. *B* and *E* are fused contractions. Stimulus train for both *C* and *F* 60 sec duration. Third row, *G*, *H* and *I*, and fourth row, *J*, *K* and *L*, are responses of slow motor units of the faster and slower types, respectively. Ordinates, grams force, on the right of each group of records to which they refer. Abscissae, seconds, immediately below each group of seconds to which they refer.

recorder ('Sanborn 320'). During recording, the muscle could be observed through a binocular stereomicroscope, which enabled an estimate to be made of the position of the motor unit within the muscle. Immediately after the experiment a photomicrograph was taken of the isolated nerve fibre, and the diameter of the fibre was then measured to the nearest micron from the photographic negative. Twenty satisfactory preparations were obtained. Individual motor units within the subgroups were typically alike, but the number of observations in each group was small; thus, in this preliminary report, the ranges of values only will be given.

A preliminary study of cross-sections of the nerve to the iliofibularis muscle showed that the diameters of myelinated nerves ranged from 2 to 20μ. Single motor nerve fibres, which covered the range 4 to 20μ, were obtained in these experiments. The results of stimulating the single nerve fibres were grouped into four classes (Fig. 1). The top row of Fig. 1 shows the response of a motor unit composed of fibres in the peripheral part of the muscle to: *A*, a single stimulus; *B*, stimulation at fusion frequency; and *C*, maintained stimulation at 30 stimuli/sec. Units of this type characteristically showed complete fatigue within about 30 sec of stimulation at a rate of 30 stimuli/sec. These units were large and gave maximum tetanic tensions of 16·8–29 g with fusion frequencies typically at about 50 stimuli/sec. The nerve fibres supplying the units were of diameter 17 to 20μ.

The second row of records (Fig. 1, *D*, *E* and *F*) presents corresponding results obtained from a fast motor unit in the centre of the muscle. These units were not as readily fatigued as those in the periphery of the muscle; they were also smaller, maximum tetanic tensions ranging from 1·0 to 13·7 g at fusion frequencies of 25 to 35 stimuli/sec. Nerve fibres supplying this group of motor units ranged from 9 to 16μ in diameter.

While the contraction times measured from single twitches in these two types of fast motor units did not differ markedly in this series of experiments, the half decay times of twitches obtained from units in the central part of the muscle were longer (40–65 msec) than those (30–40 msec) obtained with fast motor units in the periphery of the muscle.

It seems that the group of fast fibres forming a motor unit exhibit together properties sufficiently similar to the individual fibres in the same muscle, as was studied in previous work[1], to permit the conclusion that the units are homogeneous.

A slow motor unit will be defined for the present purposes as a unit which would not give a measurable contractile response after a single suprathreshold stimulus to the nerve supplying the unit, but responded to repetitive stimulation with graded contractions. This definition assumes that the motor unit has undergone a long period of rest before stimulation. The slow motor units, observed in these experiments, were separated into two types, both of which were situated in the central part of the muscle.

Responses typical of slow motor units supplied by nerves of diameters 6–10μ are illustrated in Fig. 1*G*, *H* and *I*. The nested curves in records *G* and *H* show the responses of this type of unit to repetitive stimulation at frequencies between 14 and 83 stimuli/sec. It should be noted that the rate of rise of tension in the records of Fig. 1*H* is comparable with that obtained with the fast motor unit of Fig. 1*E*. Maintained stimulation at 30 stimuli/sec gave rise to responses as shown in Fig. 1*I* and Fig. 2*A*; after reaching an initial plateau the tension showed a secondary climb.

Slow motor units supplied by nerves 4 to 5μ in diameter responded to repetitive stimulation in the manner illustrated in Fig. 1*J*, *K* and *L*. The rate of rise of tension was slow and no late increase in tension was seen on maintained repetitive stimulation. Both types of slow units were small; the maximum tetanic tensions ranged from 230 mg to 1·5 g at stimulation rates up to 100 stimuli/sec.

The group of slow motor units with the faster mechanical activity (Fig.1*G*, *H* and *I*) had unusual properties. If the train of stimuli was stopped during the late rise in tension, then small discrete contractions could be recorded in response to single test stimuli (Fig. 2*B*). This effect was never shown by the slower group of slow motor units (Fig. 1*J*, *K* and *L*). The processes behind the late rise in tension, seen during maintained stimulation in the faster group of slow motor units, are presumably connected with those responsible for the discrete responses to single stimuli. If it is assumed that this type of motor unit is homogeneous in its component muscle fibres, an assumption for which there is as yet no evidence, then a possible explanation for these effects would be found in the properties of the neuromuscular junction. Thus the discrete contractions, which could be elicited in the immediate post-tetanic period, could represent large local contractions caused by potentiation of junctional transmission. Other explanations, invoking propagated activity in the muscle fibres, are conceivable but, owing to the low

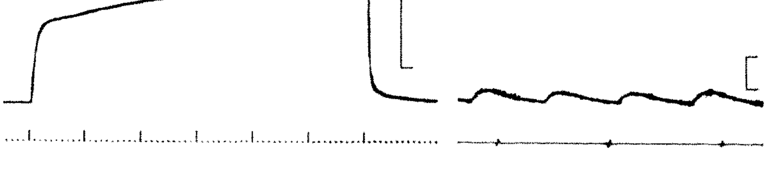

Fig. 2. Responses of a slow motor unit of the type shown in Fig. 1, *G*, *H* and *I* to repetitive stimulation of its motor nerve at 30 stimuli/sec, *A*, and to a group of four test stimuli in the immediate post-tetanic period, *B*. Abscissae: seconds and 10-sec markers in *A*, seconds in *B*. Ordinates: 250 mg force in *A* and 25 mg force in *B*.

amplitude of the discrete contractions (Fig. 2*B*), would require unusual assumptions as to the properties of the muscle fibres involved.

The evidence presented here shows that within both the fast motor unit group and the slow motor unit group motor units may show considerable differences in properties. In both the fast and slow groups of motor units, there seems to be a relationship between the properties of the motor unit and the diameter of its motor axon. The observations would satisfy several hypothetical systems from the one extreme, at which it is assumed that all properties of motor units are continuously graded from slow on through fast, to what is perhaps the other extreme at which the assumption is made that changes in properties take place step-wise and that both fast and slow motor units are divisible into two distinct types. This latter view, which is implicit in the arrangement of Fig. 1, has the merit that it lends itself to experimental testing.

BIOLOGY

Interaction of Trematodes by Predation within Natural Double Infections in the Host Snail *Indoplanorbis exustus*

THOUSANDS of snails infected with trematodes have been surveyed in the Kuala Lumpur area[1-5]. *Lymnaea rubiginosa* (Michelin), the commonest and most carefully studied snail, is infected with at least thirteen species of trematode larvae: four echinostomes, three plagiorchids, two strigeids, one *Spirorchis*, one *Trichobilharzia*, one *Fasciola* and one psilostome. Multiple infections were, however, very rare and certain trematode combinations were not found[7] and none of the few double infections found involved species with redial development[2]. The only double infections found were those in which both parasites underwent sporocyst development (producing strigeid and schistosome furcocercous or plagiorchid xiphidiocercous cercariae, personal communication from K. J. Lie).

Specimens of *Lymnaea rubiginosa* collected in the field and shedding strigeid, schistosome or plagiorchid cercariae (larvae with sporocyst patterns of development) were exposed to *Echinostoma* miracidia. These experiments confirmed that there was an "antagonism" between the trematode with only sporocyst generations and an echinostome with rediae[4]. There was no demonstrable host restriction on penetration of miracidia of the second trematode or early development of the second infection[7,8]; antagonism or interference between the two parasites occurred at later developmental stages. Production of cercaria by flukes of the sporocyst developmental type ceased soon after this stage was reached. The authors suggested that the motile rediae grazed on the schistosome sporocysts, for sporocysts were not concentrated in regions where active rediae were found. Alternatively, the rediae seemed able to kill the sporocysts by a toxic substance and then to feed on the dead larvae[8]. Similar reactions were observed in echinostome–echinostome (redia + redia) double infections[10]. Later studies with Brazilian echinostomes and *Schistosoma mansoni* in albino *Biomphalaria glabrata* confirmed and extended these findings[11].

We studied double infections of *Echinostoma malayanum* Leiper 1911 and *Schistosoma spindale* in *Indoplanorbis exustus* in a further effort to explore the interaction of trematode with trematode, using a different parasite host system, but our efforts to observe a reaction in laboratory infections were frustrated because of the 35–40 days required by *E. malayanum* to develop in the snail.

Conditions required for a large-scale experiment with doubly infected snails were provided naturally by a population of exceptionally large *I. exustus* (up to 20 mm in diameter) discovered at the outlet of an abandoned tin-mining pond at Kampong Pandan, near Kuala Lumpur. Five collections totalling 650 snails were made in February 1966. Among these, twelve were actively shedding *E. malayanum* and *S. spindale* cercariae simultaneously. Dissection showed true double infections in only ten out of the twelve; the other two had echinostome infections, but schistosome cercariae had entered the mantle cavity from the outside or may have adhered to the surface of the shell. Later these fork-tailed cercariae reappeared in the water to simulate a normal shedding of cercaria. Dissection of all snails collected throughout the month demonstrated a true double infection in forty-seven of them (Table 1). In addition to the ten snails shedding both types of cercariae, we found double infections in thirty snails that were shedding only schistosome cercariae, and in three snails shedding only echinostome cercariae. Four other snails also proved to be doubly positive, although they were shedding neither cercaria at the time. The schistosome infections in these hosts were largely displaced by a vigorous development of echinostomes.

One snail was shedding fork-tailed cercariae of *S. spindale* as well as amphistone cercariae, and four were shedding schistosome and xiphidiocercariae, indicating a twin sporocyst-type of infection. In the latter group only three snails were infected on dissection, a further indication that "shed" larvae found in the water with snails collected in the field may be unreliable.

These unexpected double infections in the wild were the first such discovery among many thousands of snails from dozens of sites. They also appeared at a level well

Table 1. NATURAL DOUBLE INFECTIONS IN *Indoplanorbis exustus*

Data from 650 snails, Kampong Pandan, Malaysia, February 1966. S, *Schistosoma spindale*; E, *Echinostoma malayanum*; A, amphistome cercariae; X, xiphidio cercaria.

* Recorded "shed" includes snails into which cercariae swam and emerged up to 24 h later. This method of analysis proved unreliable and so was considered a first approximation only. True infection levels and incidence can only be determined by dissection and examination of each test snail.

above that expected assuming a probability of double infections to be random, that is the product of the infection rates for each of the separate species.

In the dissected snails, *S. spindale* was present in 21·2 per cent of the 650 snails, *E. malayanum* in 13·5 per cent to give a predicted level, based on random distribution, of 2·9 per cent double infections. Actually 7·2 per cent, or two and a half times the expected proportion, of the *Indoplanorbis* collected from this site were simultaneously infected with the two flukes. Double sporocyst infections (schistosome plus plagiorchid) occurred in 0·46 per cent of the total (3 of 650 snails), whereas prediction by random distribution would give only 0·06 per cent of these double infections. Only one snail was shedding xiphidiocercariae, whereas three were shedding xiphidio and furcocercous cercariae simultaneously. Double infections of the schistosome with an echinostome in a greater proportion than that predicted by random distribution may have occurred entirely by chance, or it may have been caused by reduced host resistance to a second infection in snails already carrying a different infection. In either case, it was remarkable to find so many double infections, considering the rapid loss of doubly infected snails in our laboratory conditions. It also attests to our lack of understanding of the optimum conditions required by infected snails.

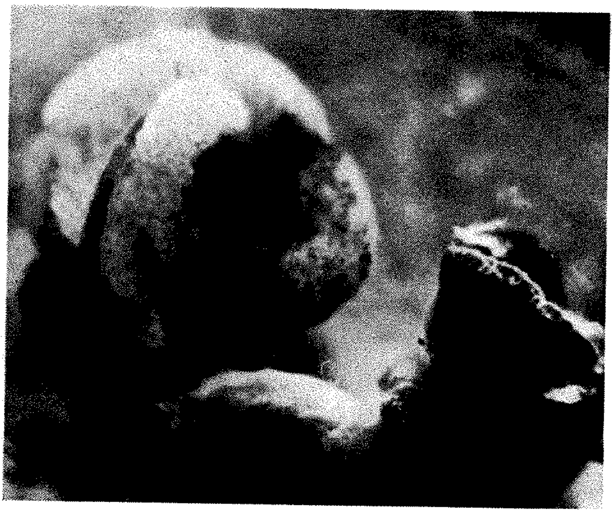

Fig. 1. Grape-like cluster of sporocysts of *Schistosoma spindale* alongside gut of *Indoplanorbis exustus*.

During dissection of the doubly infected snails, we made extended observations of the living and active rediae on and in the intact body of the de-shelled snail. Daughter rediae could be seen crawling over the surface of the digestive organ, particularly within the arch of the whorl, and over the ovotestis near the tip of the viscera. In areas of redial concentration, few if any schistosome sporocysts were observed. Typically, a heavy mass of sporocysts, threaded into the tissues, was concentrated in the midzone of the digestive gland or was hanging from this region in grape-like clusters (Fig. 1). Rediae were moving about the periphery of this mass, but a few could also be seen among the sporocysts. Some rediae were lying next to sporocysts and apparently consuming them.

A series of observations of infected snail tissue confirmed that sporocysts were being devoured by rediae. Infected tissues were removed intact and preparations were studied microscopically both with and without a coverslip. Despite this disturbance, larval activity in and around the snail tissues continued for about 30 min.

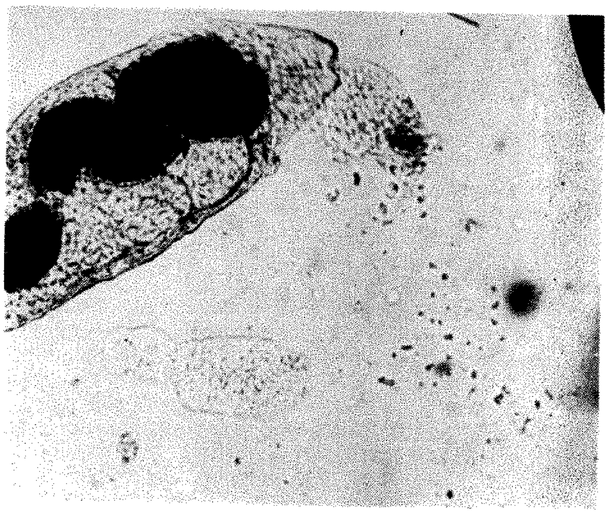

Fig. 2. Daughter redia of *Echinostoma malayanum* ingesting a sporocyst of *S. spindale* it has captured.

One redia had a third of a sporocyst lying within its pharynx, another a sporocyst in the oral opening; a third had almost the entire larva consumed, with only a small portion still protruding (Fig. 2). Cannibalistic activities are known among echinostome rediae. Wesenberg-Lund[12] describes daughter rediae feeding on other daughter rediae within the mother rediae; Nasir[13] found remains of rediae in the gut of *E. nudicaudatum* rediae, both in mother rediae and in daughter rediae free in the snail tissues.

Most surprising, however, was our observation that rediae can capture and ingest swimming cercariae, although the cercariae are far more active and motile than the rediae. Three such cases were observed: one redia made a movement towards a thrashing schistosome cercaria, snatched at it rapidly and captured it by the midbody, swallowing the entire cercaria within a minute or two. Another redia held the body of a cercaria within its pharynx, forked tail still protruding (Fig. 3). Still another caught a schistosome cercaria by the tail, with the anterior body portion protruding and attempting to escape. Undoubtedly the highly muscular pharyngeal apparatus of the redia provides a sucking structure that serves the larva admirably for both capture and swallowing

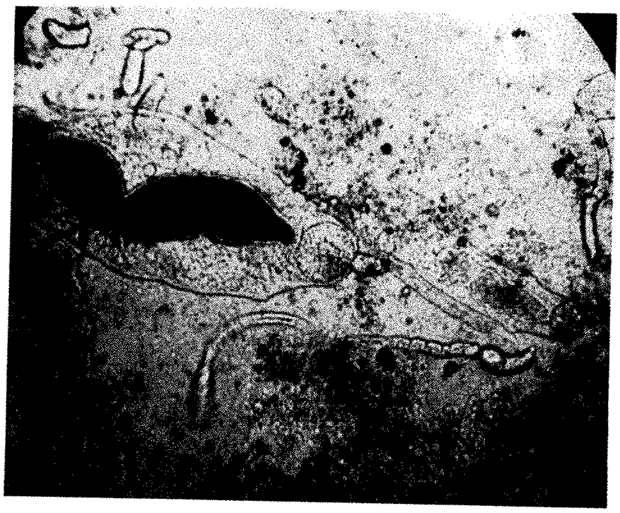

Fig. 3. Redia of *E. malayanum* consuming a cercaria of *S. spindale* it has captured. Tail of cercaria with fork collapsed visibly protruding from mouth of redia.

of its parasitic prey as well as for ingestion of host tissues. There was, however, no indication of cannibalism.

Clearly, the "antagonism" between *S. spindale* and *E. malayanum* is direct predation in this instance. How the schistosome larvae managed to survive in this series of hosts long enough to show both kinds of cercariae in the same snail is not known. A critical factor was the precise stage of development of each parasite species at the time the snails were collected. The outlet of the tin-mining pond where the *Indoplanorbis* were found is part of a hyperendemic region of *S. spindale* infection in goats and cattle maintained by the local Indian community. Conceivably, snails in this pond were free of *Echinostoma malayanum* (carried chiefly by pigs and rodents), and a sudden influx of infected faeces about 6 weeks before our first February collection may have exposed them to large numbers of *E. malayanum*. A group of heavily infected swine usually maintained elsewhere could have provided the echinostome miracidia had they been moved into this pond area, a not infrequent occurrence.

The doubly infected snails which we examined showed that the echinostome infection was ascending and the schistosome one descending. Where only schistosome cercariae were being shed, the echinostomes were seen chiefly as young daughter rediae. Where both cercariae were being shed, the echinostome infection was far heavier. Where only echinostomes were producing cercariae, the remaining schistosome sporocysts were few and scattered, obviously nearly eliminated. All doubly infected snails were the largest hosts (15–20 mm), whereas single infections were found chiefly among the 10–15 mm snails. This growth phenomenon, though not uniform or constant, has been reported in a number of snail species parasitized with larval trematodes[14,15].

We surveyed the Kampong Pandan area both before and after the discovery of the doubly infected snails. *E. malayanum* is present at a relatively low level in this region (up to about 10 per cent of the snails in an average collection). *S. spindale* is usually present in a larger percentage of the *Indoplanorbis*, reaching about 50 per cent in the vicinity of dairies where grazing cattle are numerous (and there are few echinostomes present). Snails with double infections were found later in the same site, but in a smaller proportion of snails examined than in the collection analysed here.

Later another double infection at a high level was found in a colony of very large *Indoplanorbis* snails in a roadside stream near Kampong Bohol, 6·5 miles from Kuala Lumpur. This second find in *Indoplanorbis* and our failure to locate a double infection in *Lymnaea* suggest that trematode repression of one species by another is at least in part a matter of balance between parasite and host, varying with the degree of adaptation of each species to its particular host, as emphasized by Lie *et al.*[6]. An example of conditions which appear to favour the predator is found in the combination of *Echinostoma audyi* (or *Echinoparyphium dunni*) and *Trichobilharzia* in *Lymnaea rubiginosa*. An opposite example, in which a well adapted schistome is difficult to eradicate from its snail host by an apparently less well adapted species of echinostome, is the *S. mansoni–Echinostoma barbosai* system in *Biomphalaria glabrata*[7]. The natural infections reported here from *Indoplanorbis*, *E. malayanum* plus *S. spindale*, represent an intermediate stage of adaptation in which the predator can wipe out its neighbouring parasite but does not necessarily do so before schistosome cercarial production begins. The success of this part of the reproductive phase is of special significance if double infections are to be considered as potential biological weapons against human schistosomiasis.

We think that the following points from these observations are important. (1) The trematode redial stage is not only a parasite within its snail host but can also act as a predator that seeks and devours developmental stages of other flukes in the same snail.

(2) There is need for exploration of this phenomenon as a possible supplementary biological weapon against human schistosomes, one that might function within the snail host without the entire snail population having to be destroyed. To develop the tools for such a potential biological control, however, each area of human or animal disease must be evaluated ecologically. It is necessary to determine the appropriate predator–parasite and prey–parasite balance and their mutual adaptation to a particular host. It is possible to introduce a new parasite into the environment to attack a resident schistosome focus. This should be approached only after the predator's anti-schistosome and host–parasite characteristics have been fully tested in laboratory and field-plot studies. We undertook a small field study in Malaya to test the feasibility of this approach, using the combination of *S. spindale* and *E. malayanum*[16]. Initial success of this effort shows that further search for such a biological weapon is justified. It will, however, require specific tailoring and application of each combination of trematode and host to the area in which it is applied.

Effect of β-Indolylacetic Acid on the Growth and the Auxin Catabolism of *Lactobacillus bulgaricus*

ENDOGENOUS auxin may act in the regulation of bacteria growth[1], although its precise role is as yet poorly understood[2]. For example, *Lactobacillus* can grow without auxin[3]; however, in the presence of β-indolylacetic acid (IAA), its multiplication can be strongly modified[4]. In the following experiments, *Lactobacillus bulgaricus* (strain 1416, Liebefeld Institute of Dairy Research) was used and the medium was *Lactobacillus* broth *AOAC* (Difco). For each series of growth measurements, tubes containing 10 ml. of medium (with IAA) were inoculated with 1 ml. of a young culture of *Lactobacillus* (standard: 0·416 ml. of protein). The cultures were incubated at 37° C and the growth was measured after 6 and 12 h. Two methods were found most satisfactory for the growth determinations. The first is related to a direct measurement of the increase in turbidity[5], using the 'Lumetron 402 *E*' with a double photoelectric cell. The second is based on the analysis of the total protein content[6]. The protein was determined by precipitating the washed

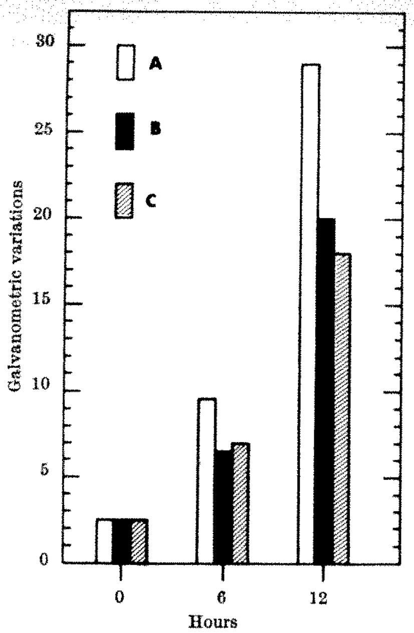

Fig. 1. Growth of *Lactobacillus bulgaricus* (in terms of turbidity: galvanometric variations). Time of incubation, 0, 6 and 12 h. *A*, Control; *B*, 1×10^{-5} molar β-indolylacetic acid; *C*, 1×10^{-3} molar β-indolylacetic acid.

bacteria cells with trichloroacetic acid. Comparing the turbidity with a series of standard solutions of serum–albumin, precipitated with trichloroacetic acid, a good correlation was found. Further examination of this technique will be discussed elsewhere.

It can be seen in Fig. 1 that the growth (in terms of turbidity) increases with time. After 6 and 12 h, IAA causes an inhibition for the two concentrations tested. In Fig. 2, the increase with time in protein content is shown. IAA produces an initial repression of the growth. But, after 8 to 10 h, the logarithmic growth phase[4] of the *Lactobacillus* treated with $1 \cdot 10^{-5}$ molar IAA continues to increase while with 1×10^{-3} molar IAA or without IAA the growth rate is lower and quickly approaches the stationary phase.

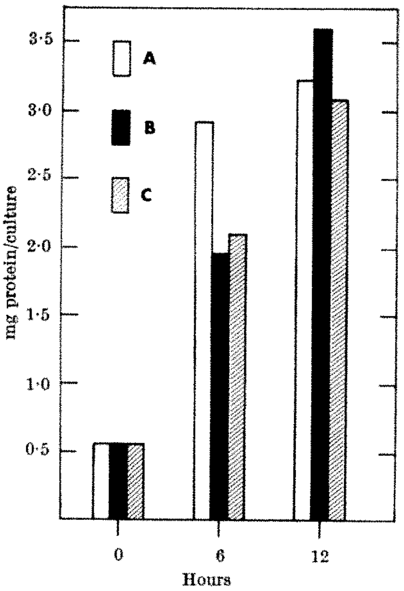

Fig. 2. Protein content of *Lactobacillus bulgaricus* (in mg of protein/culture). Time of incubation, 0, 6 and 12 h. *A*, Control; *B*, 1×10^{-5} molar β-indolylacetic acid; *C*, 1×10^{-3} molar β-indolylacetic acid.

To understand the action of exogenous auxin on the growth of *Lactobacillus*, the IAA-oxidase of this bacteria was analysed. It is well known that IAA-oxidase catalyses the oxidation of IAA[7]; conversely, IAA alters the *in vivo* activity of IAA-oxidase[8,9]. These facts suggest that the mutual interaction between hormone and enzyme may be important in the control of growth[10,11].

The preparation of the IAA-oxidase has been described before[12]. *In vitro*, IAA destruction assays were carried out with lyophilized *Lactobacillus* and cold buffer (0·1 molar; *p*H 6·1). The mixture was first centrifuged (3,500*g*, 15 min), the extract was added to the buffer for a second centrifugation (8,000*g*, 10 min) and the supernatants were made up to 10 ml. with buffer. Two ml. of the active solution was mixed with 2 ml. of deionized water and 4 ml. of cold buffer. At zero time, 2 ml. of IAA (50 μg/ml.) was added. The mixture was incubated in a metabolic shaking incubator (28° C) in complete darkness. Initial and residual IAA was determined by colorimetric analysis (modified Salkowski reaction)[13].

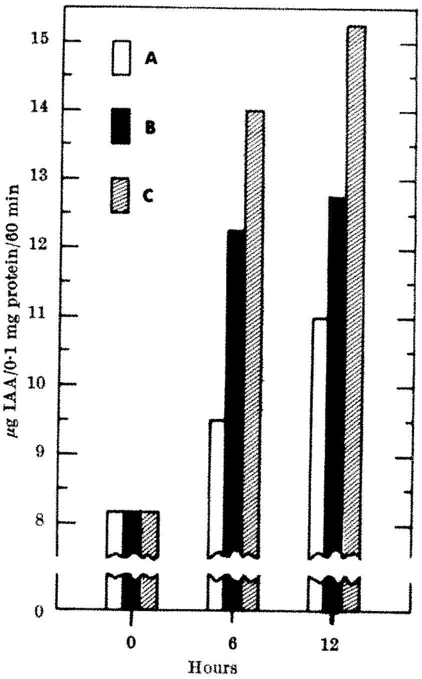

Fig. 3. Activity of β-indolylacetic acid-oxidase (expressed in μg of β-indolylacetic acid destroyed/0·1 mg of protein and for 60 min) from *Lactobacillus bulgaricus*. Time of incubation, 0, 6 and 12 h. *A*, Control; *B*, 1×10^{-5} molar β-indolylacetic acid; *C*, 1×10^{-3} molar β-indolylacetic acid.

Analyses of the IAA-oxidase activity clearly show (Fig. 3) that (1) the enzyme activity increases with the duration of culture, and (2) the exogenous IAA causes a strong stimulation of the IAA-oxidase which is greater for the high IAA level.

As it has been observed, for plant tissues[14,15], it is possible to enhance the activity of the IAA-oxidase, prepared from *Lactobacillus*, by incubating cells in IAA. If, on the other hand, the activity of these enzymes is increasing, the level of the endogenous auxins is decreasing, as was also shown in plant cells[10,11]. Finally, if the auxin content is decreasing, the growth will also be reduced. Such "adaptive increase" of the IAA-oxidase activity could explain the reduction—which was observed in the present experiment—of the growth of *Lactobacillus* caused by IAA.

Non-local Nature of Habituation in a Rotifer and Protozoan

HABITUATION, defined as a "waning of a response as a result of repeated stimulation"[1], can be considered to be a form of learning if fatigue, injury and local sensory adaptation can be ruled out. This is the case when an organism shows the same behaviour response to a different or more intense stimulus after habituation. The usual way to ascertain whether there is local sensory adaptation is by recording electrically the relevant sensory pathways; this is often quite difficult, either because the nerves are too small or are too numerous to record from. It is possible to design behavioural experiments to test for non-local habituation; among the invertebrates[1], however, this is only possessed by planarians[2].

Several freshwater micrometazoa were shown to habituate to a mechanical shock[3], but only the rotifer *Philodina* and the protozoan *Spirostomum* were found to be useful in a test for non-locality of the habituation response. The others either moved too fast to habituate at two different areas of their body or else were sensitive to the stimulus at only one area.

One rotifer at a time was placed in a depression slide and left there for 5 min before being presented with the stimulus. Thirty sessile rotifers were first lightly touched with a fine wire on the corona every 5 sec until they no longer contracted to three stimuli in a row. Five sec after habituation, the same stimulus was applied to the lower body area near the pedal gland until each rotifer met the previous habituation criterion. To guard against the possibility that the posterior area was initially less sensitive than the corona area, another thirty rotifers were given the stimulus in reverse order. Because the intensity of the stimulus determines the rate of habituation[3], it is important that all the stimuli should be of essentially the same magnitude to avoid any bias in the results. Unfortunately, if two people habituate the animal in a blind experiment, this only introduces more variation in stimulus intensity.

Each protozoan was also kept in a depression slide for 5 min before the experiment began. Then each one of the thirty was presented with a mechanical shock in the form of a solenoid which dropped a constant height from its de-energized coil every 5 sec until the animal no longer contracted to three stimuli in a row. Taking advantage of the fact that when a *Spirostomum* is cut in two both halves can still contract to a stimulus[4], each protozoan was cut transversely into approximately two equal halves with a razor blade. Fifteen seconds later, the anterior and posterior parts were habituated in the same way. To avoid the possibility that the cutting reduced the sensitivity of the parts to the stimulus, thirty unhabituated (naive) protozoa were cut in half; 15 sec later both parts were habituated. It is important that the cutting should be done cleanly and quickly or else the animals become insensitive to subsequent stimuli for the next few minutes. Furthermore, the protozoan must be cut into two nearly equal pieces, for a larger piece is more sensitive to the stimulus than a smaller one[4].

The results are presented in Tables 1 and 2. The heading "No. of stimuli to habituate" shows how many stimuli it takes before the organisms do not respond to three more stimuli in a row. In the rotifer, after the corona had been habituated with an average of 8·8 stimuli, the lower body area needed only three stimuli before the animal ceased to contract. When the lower body area was stimulated first and habituated with 8·2 stimuli, the corona area needed only 2·4 stimuli to habituate the animal. These differences are significant at $P = 0{\cdot}001$, as judged by the *t* test for the difference between correlated means, as are those differences (by the standard *t* test) between the number of stimuli it takes to habituate one specific area first and the number it takes to habituate the same area after habituating the other area. The experiment with *Spirostomum* demonstrates that while it takes nine stimuli to habituate the whole organism, only about three are needed to habituate its severed anterior and posterior pieces. By the *t* test for correlated means, this is significant at $P = 0{\cdot}001$. It takes more stimuli than this ($P = 0{\cdot}005$) to habituate the anteriors and posteriors from a previously naive organism. While there is relatively large variation in the number of stimuli needed to reach habituation in each of the areas stimulated, it should be noted that fifty-four of the sixty rotifers showed some retention of habituation when re-tested in another area, and, for the protozoa, twenty-seven out of thirty anterior pieces and twenty-five out of thirty posterior ones showed retention.

Table 1. HABITUATION IN *Philodina*

	No. of stimuli to habituate			
	1. Corona	2. Body	1. Body	2. Corona
Mean	8·8	3·0	8·2	2·4
Standard deviation	5·5	3·1	5·6	2·2

Table 2. HABITUATION IN *Spirostomum*

	No. of stimuli to habituate				
	Whole organism	Anterior	Posterior	Naive anterior	Naive posterior
Mean	9·0	3·1	3·6	7·0	9·6
Standard deviation	6·9	2·9	3·1	4·1	6·1

When *Philodina* is habituated in the area of the corona so that it no longer contracts to touch, the lower body area near the pedal gland becomes partly habituated. This lower body area is not any less sensitive to the stimulus than the corona because, when the body is habituated first, the corona also becomes partly habituated. When a *Spirostomum* is habituated so that it ceases to contract to a mechanical stimulus and is then cut in half transversely, the anterior and posterior pieces are also partly habituated. Habituating the cut pieces of a naive protozoan requires more stimuli than the pieces from a previously habituated one. The anterior and posterior parts from a previously habituated protozoan are equally sensitive (3·1 as compared with 3·6) to the stimulus, but a naive anterior is less sensitive ($P = 0{\cdot}01$) to the stimulus than the naive posterior (7·0 as compared with 9·6). Neither, however, are significantly different (at $P = 0{\cdot}05$) from a whole organism in terms of the stimuli needed to reach habituation.

After habituation of *Spirostomum*, or its anterior and posterior halves, to the mechanical stimulus, it still contracts either to a more intense stimulus which is given in the same way, or to direct touch on its body. The rotifers, too, after habituation to the touch stimulus, will contract either to a mechanical shock which is delivered by the solenoid arrangement or to a more intense touch stimulus. These organisms also return within expected statistical limits to their normal levels of sensitivity several minutes after habituation[3]. It can be concluded therefore that habituation in these two organisms cannot be explained by fatigue, injury or local sensory adaptation. This conclusion, as well as the small size and phylogenetic simplicity of these organisms, and the ease of obtaining habituation, suggests that these animals could be used in studies concerning the physiology of learning and memory.

ANIMAL BEHAVIOUR

Rats prefer the Home Cage to the Runway following Intermittent but not Consistent Reinforcement

SEVERAL sources of evidence suggest that, in both the Skinner box and runway, an intermittent schedule of reinforcement could be a source of aversion. Time-out studies show that when a pigeon or rat can turn off a stimulus which is associated with a particular reinforcement schedule, the frequency and duration for which it does so vary inversely with the probability of reinforcement[1,2]. Furthermore, when rats or pigeons are given a choice between equal schedules of reinforcement which are predictable in one case and unpredictable in another, they choose the former[3,4].

Although aversion has been attributed to the intermittent schedule in the runway[5], no direct test of this interpretation seems to have been made. A simple test can be made by offering a choice between the runway and, for example, the home cage. Intermittently reinforced rats run faster when placed in the runway, but if given a choice between entering the runway or going back to the home cage, they choose to go to the home cage rather than to the runway, and do so more frequently than a consistently reinforced group do.

The subjects were twelve 90-day-old male albino rats of the Sprague–Dawley strain. They were randomly divided into two equal groups: a continuously reinforced group (group *C*) and a partially reinforced group (group *P*). The apparatus consisted of a straight alley (60 × 6 × 9 in.) of unpainted redwood covered with clear 'Plexiglass'. Interruption of any of four photobeams started and/or stopped one of three standard electric clocks. The first clock measured the time taken over the first 6 in. of the alley, the second clock measured the time taken to run over a distance of 32 in., and the third clock measured the time taken over the last 6 in. (goal time). A 7 × 7 in. 'Plexiglass' platform was permanently attached on one side to the start box; the other side could be hooked to the specially designed home cage. The rat was placed on the platform and was allowed to step down into either the starting box or else its home cage.

The rats were deprived of food for 23 h and were housed individually in the special home cages. All rats were given 'Purina' lab chow in the home cage for 30 min each day, approximately 30 min after the last test trial. Water was always available. Following pretraining, each rat was given eighty-eight trials in the runway, four each day, at an average inter-trial interval of approximately 8 min. Group *C* received four Noyes pellets of 45 mg on each of its four daily trials, whereas group *P* received the same number of pellets on half of its trials. The choice procedure was initiated on the day following the last acquisition trial.

Three kinds of trials were used in the choice procedure: (*a*) standard trials of a kind which had been given (rat placed in start box and removed at the end of the run); (*b*) choice trials; (*c*) forced trials. At the start of each day the rat was placed on the platform and given a choice. If it chose the runway it was then given three standard trials; if it chose the home cage it was then given four standard trials (making a total of four runway trials in both cases). Next, a second choice was administered followed by a forced trial, and then a third choice was given, followed by a forced trial. Forced trials served to equate the number of runway trials for the two groups. By placing the rat on the platform and blocking the entry to either runway or home cage, the rat was forced to take the alternative it had not taken on the preceding choice trial. The reinforcement schedule was preserved throughout the procedure; that is, group *C* received reinforcement on all trials, while group *P* received 50 per cent random reinforcement on choice and forced trials as well as on standard trials. In brief, the rat was given three choices each day between entering the runway or returning to the unbaited home cage; one such choice was given at the start of the day, and two others were given following a block of standard runway trials.

Figs. 1 and 2 show the performance during the first eighty-eight trials before the choice procedure was introduced. The findings were as follows: group *P* surpassed group *C* in the speed of the start (as well as speed of run, which is not presented because it was comparable with speed of start), whereas group *C* was faster in the goal box. An analysis of variance on the speed of start before and after the reversal showed that the reinforcement by trials interaction was significant ($F = 5{\cdot}479$, df $= 1/10$, $P < 0{\cdot}05$). This supports the conclusions suggested by Fig. 1 as well as previously reported outcomes[6]. A similar analysis of variance which was performed on speeds over the last 6 in. for the last 3 days of acquisition trials showed that the chief reinforcement effect was significant ($F = 4{\cdot}984$, df $= 1/10$, $P < 0{\cdot}05$), while the interaction (reinforcement by trials) effect was not ($F < 1{\cdot}0$).

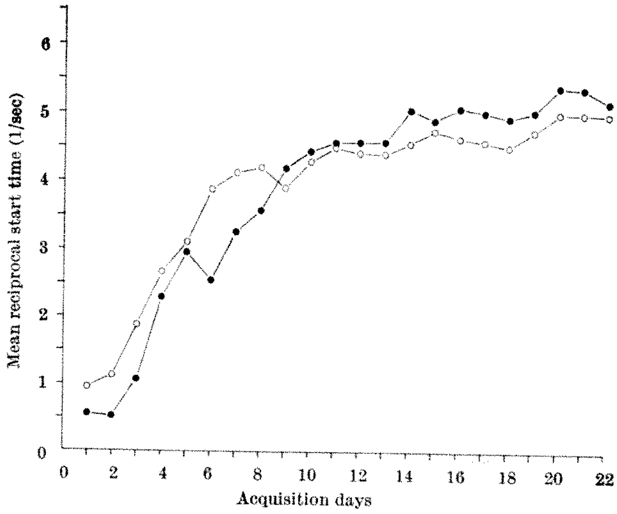

Fig. 1. Mean reciprocal starting times; each point is based on the four trials which were given on each day. ●, *P*; ○, *C*.

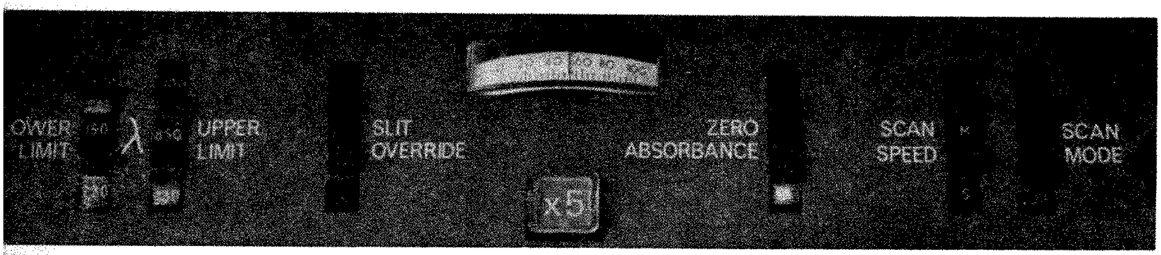
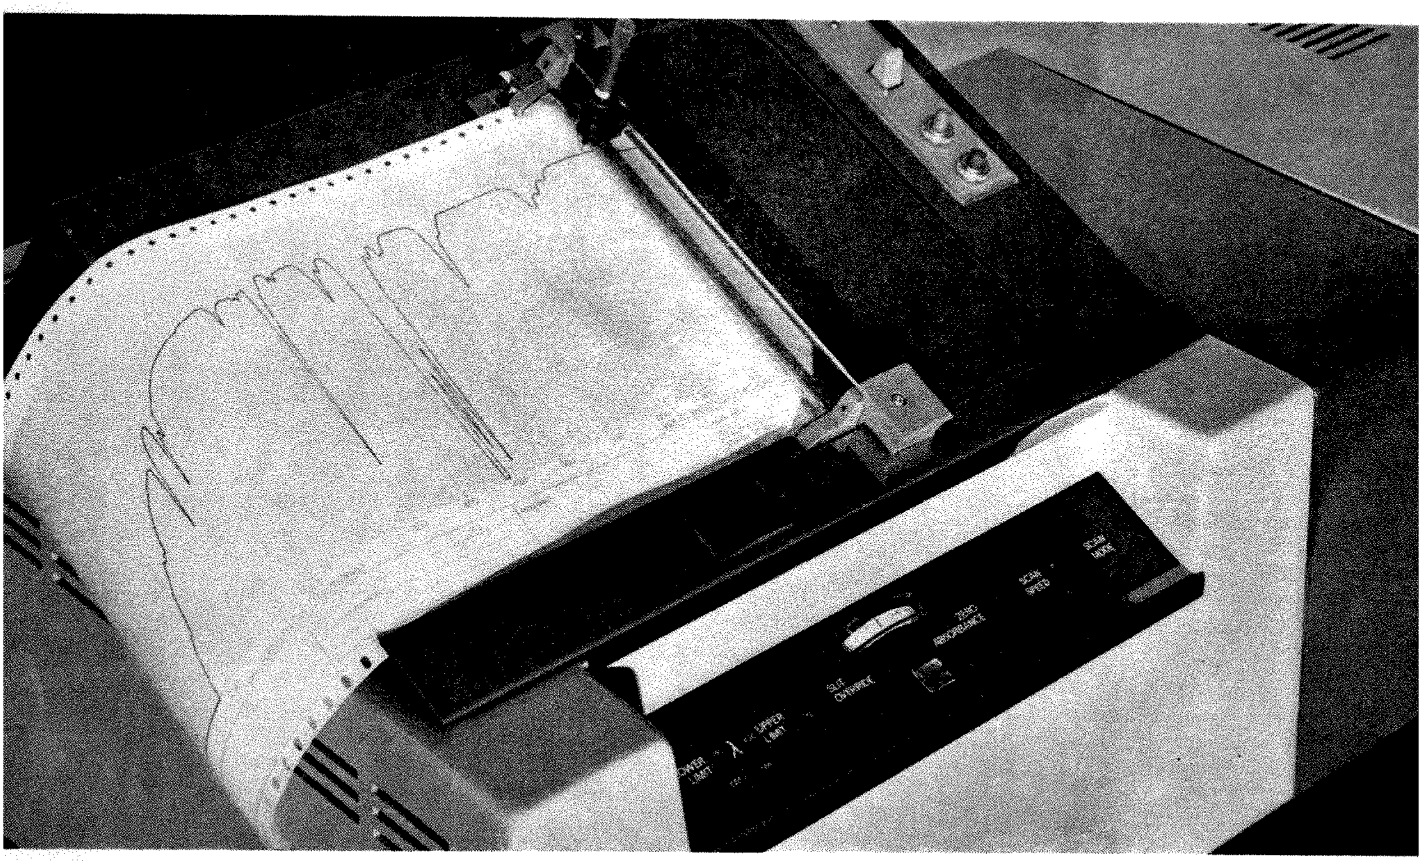
Data for the three choices which were given each day are presented in Fig. 3. The hypothesis is shown to be well supported by the choice data, equally by the choice at the start of the day and by those choices following the runway trials. The first two choices can be discounted on the grounds that they served as adaptation trials; on all subsequent trials, group *C* chose the runway more



Set these controls on Perkin-Elmer's new U.V. Spectrophotometer and scan any wavelength range between 190—850 nm



rkin-Elmer's new Model 2 Ultraviolet and Visible ectrophotometer has a ique wavelength control stem. By setting upper and ver limit stops, you can an any wavelength range gly or repetitively and esent the spectra sequen-lly or superimposed.

u can scan the full range m 190 to 850 nm on a single art in 2, 10 or 40 minutes.

You can expand the linear absorbance scale five times so that 0.3 absorbance units fills the chart.

You can perform kinetic studies at a fixed wavelength.

You can insert a new roll of paper into the flow chart recorder in 30 seconds and record 40 rull range spectra without changing it.

You can choose from a wide range of accessories including a thermostatted multiple sampling unit - ideal for enzyme reaction studies.

You can get faster, more accurate results over a larger range of applications with this highly automated instrument.

You can get details immediately from Perkin-Elmer Ltd. Beaconsfield, Bucks. Telephone: Beaconsfield 2571, Telex: 83257 or Manchester Central 2569.

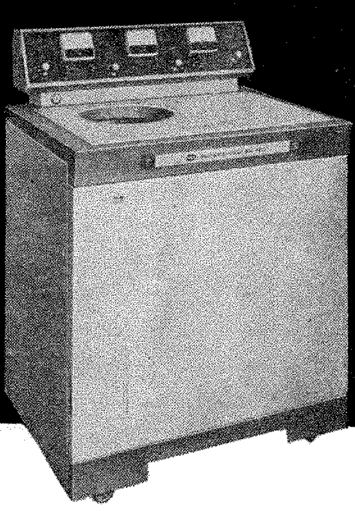
PERKIN-ELMER

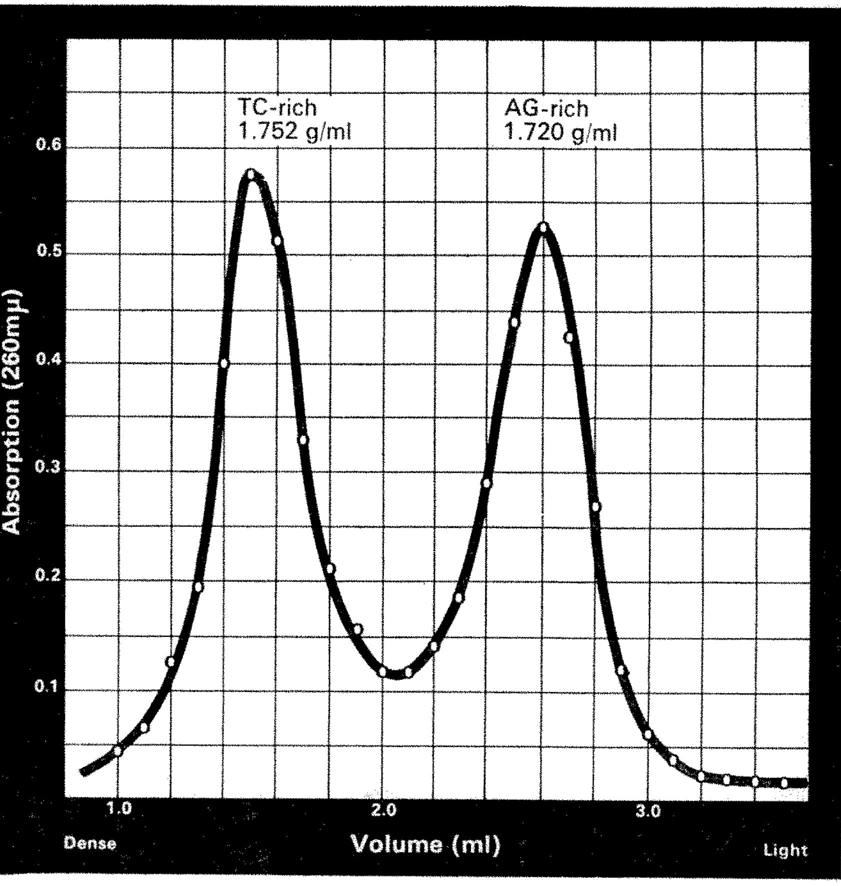
We have always stressed (among other things) the precise temperature control and exceptional rotor stability throughout the speed range of ***MSE SUPER SPEED PREPARATIVE ULTRACENTRIFUGES***

For instance, they made this possible:—

'FIRST TIME EVER'

Separation of the complementary strands of mouse satellite DNA using an Angle Rotor.





50 μg. of mouse satellite DNA in Tris-HCl buffer was treated with sodium lauryl sulphate at pH 12.7 and centrifuged in a caesium chloride gradient (initial density 1.765 g/ml at 25°C) for 20hr. at 42,000 r.p.m. at 25°C.

This separation was carried out on an MSE Super Speed 50 Preparative Ultracentrifuge using the 10 x 10ml angle rotor instead of the more usual swing-out rotor. Full details of the procedure are given in MSE Application Sheet No. 2, available on request.

Precise automatic control facilities, outstanding stability of temperature and an automatic oil recirculation system make MSE Super Speed Centrifuges ideal for the lengthiest and most exacting density gradient runs—in addition to their other applications.

1966 THE QUEEN'S AWARD TO INDUSTRY

GD980

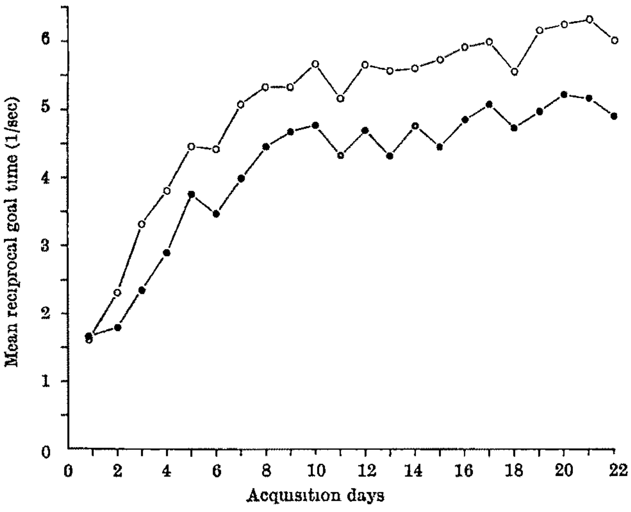

Fig 2 Mean reciprocal goal box times, each point is based on the four trials which were given on each day ●, *P*, ○, *C*

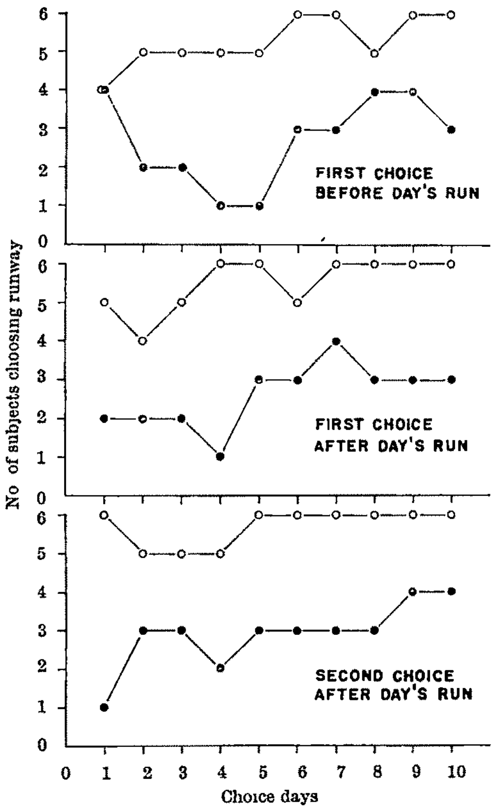

Fig 3 Number of subjects choosing to enter the runway on each of three choices which were given each day ●, *P*, ○, *C*

often than group *P*. This difference was highly significant on the first day of choice ($P<0.007$ by Fisher's exact test), and was maintained over all subsequent choices For example, with the last ninety choices (days 6–10), group *C* chose the runway eighty-eight times, compared with only fifty times for group *P* Except for one rat in group *P* which always chose the runway, the individual choice behaviour of the group *P* rats was compatible with the group average one always chose the home cage while the other four chose about equally between the two alternatives

Do the choice data provide clear evidence of the acquired aversion of the runway as a result of the associated intermittent schedule? Consider some alternative interpretations, for example, "probability matching" This interpretation is encouraged by the approximate agreement between the proportion of runway choices which were made by the two groups and the proportion of these choices which were reinforced But this reasoning cannot be depended on for several reasons First, if choice were determined by reinforcement the groups should diverge increasingly over the course of the 10 days of choice In fact, they differed as much on the first day as on succeeding days (Fig 3) Indeed, the difference which was already evident on the second choice of the first day could not be attributed to differential reinforcement of choice behaviour because on the first choice the groups were treated alike That is, on the first adaptation trial an equal number of subjects from both groups chose the runway, and the runway trial was reinforced not only for group *C* but also for group *P* The data for choice must therefore reflect the previous reinforcement which was given for runs in (and not choice of) the runway (A further reason for discounting this interpretation is that a proper test of probability matching requires that the alternatives which are offered should be equal except for their probabilities of reinforcement, it is not apparent that the runway and home cage comprise alternatives that differ only in their probabilities of reinforcement)

Another objection is that group *P* chose the home cage not because the runway was more aversive for the rats in this group than for group *C* but because the home cage was more attractive for these than for the rats in group *C* This objection, however, does not explain why group *P* rats should value the home cage more than group *C* rats when in fact both groups were similarly treated in the home cage (but, of course, differently in runway) Finally, the choice data might be attributed to the difference in total amount of food which was received by the two groups, but such reasoning would lead to the prediction that group *C* should run faster than group *P*, which is contradicted by this study and other similar ones

APPLIED SCIENCE

Plant Competition and Crop Yield

Shinozaki and Kira[1] by combining a logistic equation of population growth (equation (1)) with the law of constant final yield (equation (2)) derived equation (3) to describe the relationship between plant density and yield

$$\frac{1}{w}\frac{\mathrm{d}w}{\mathrm{d}t} = \lambda(t)\left(1-\frac{w}{W}\right) \qquad (1)$$

or

$$w = \frac{W}{1+ke^{-T}} \text{ and } T = \int \lambda(t)\mathrm{d}t$$

$$W\rho = Y = \text{constant} \qquad (2)$$

$$\frac{1}{w} = a + b\rho$$

$$a = \frac{e^{-T}}{w_0} \text{ and } b = \frac{1 - e^{-T}}{Y} \qquad (3)$$

where at a given time t, w is the dry weight of each plant and W is the asymptote of w, λ is the coefficient of growth which is independent of plant density ρ, k is the integration constant, determined by the initial conditions and independent of plant density, Y is the final yield/unit area, and independent of density, and w_0 is w at $t=0$ The law of constant final yield, however, may not always be satisfied (data to be published elsewhere) and the yield in higher densities may decline In these conditions, equation (3) cannot describe the yield–density relationship The validity of the logistic equation (equation (1)), as tested for different crops[1,2], has proved to be justified so far, and it seems that it is the law of constant final yield which needs further modification

As stated by Shinozaki and Kira[1], the law of constant final yield is equivalent to equation (4) if the power, α, is taken as unity at the end of the growing season

$$\log W = \log K - \alpha \log \rho$$

or

$$W = K\rho^{-\alpha} \qquad (4)$$

where K and α are constants This relationship is valid when $\rho \gg C$, where C is the plant density at which competition starts, before this point W is independent of ρ If $\alpha = 1$, then $K = Y$

Equation (4) can be modified and re-written as

$$\log W = \log A - \alpha \log (\rho/C)$$

or

$$W = A(\rho/C)^{-\alpha} \qquad (5)$$

where A is the weight per plant when $\rho \leqslant C$, that is, in absence of competition When $\alpha = 1$, the law of constant final yield can be written as

$$W\rho = A\,C = Y = \text{constant} \qquad (2)$$

We propose that equation (5), which is a more general form of equation (2), can be combined with equation (1) and the following equation can be derived

$$\frac{1}{w} = a + b\rho^{a} \qquad (6)$$

where

$$a = \frac{e^{-T}}{w_0} \text{ and } b = \frac{1-e^{-T}}{AC^{a}}$$

and considering that $y = w\rho$, we got

$$y = \frac{\rho}{a + b^{a}} \qquad (7)$$

Equations (6) and (7), as any other formula given for competition, are valid only when $\rho \gg C$ (that is when there is competition at the end of the growing season) When $\alpha = 1$, equation (6) or (7) becomes the same as equation (3) which was derived by Shinozaki and Kira[1], and also independently by Holliday[3] and de Wit[4], and the law of constant final yield is satisfied When $\alpha > 1$, equation (7) suggests that the yield/unit area reaches a maximum at a certain density and declines with further increasing density.

In plant density experiments with different varieties or with different degrees of environmental growth factors, parameter b in equation (6), containing A and C, would possibly change more with the potential of the environment, while the dominant factor in parameter a might be the genetical character, however, this generalization will be modified with time Changes in α with the treatment suggest that there is an interaction between plant density and the level of treatment applied If the logistic equation of growth is valid for the growth of a plant part, equation (6) or (7) can also be used to describe the relationship between the yield of a plant part and density Furthermore, it can be suggested that when the basic assumptions given here are valid for competition in mixed communities, equation (6) or (7) can be used to describe the relationship between plant density and yield of individual species or varieties Equation (9) is a combination of the law of allometry (equation (8)) and equation (6)

$$w = Hw_p^{\theta} \qquad (8)$$

where w is weight per plant, w_p = weight of plant part, H and θ are constants

$$w_p^{-\theta} = a_1 + b_1\rho^{\alpha} \qquad (9)$$

where $a_1 = Ha$ and $b_1 = Hb$

and when $\alpha = 1$, as suggested by Shinozaki and Kira[1], equation (9) becomes

$$w_p^{-\theta} = a_1 + b_1\rho \qquad (10)$$

Equation (9) or (10) describes the way plant density affects the distribution of dry matter into plant parts, and it can be proved that by the end of the growing season $\theta \rightarrow \alpha/\alpha_p$, where α and α_p are the power α calculated for total plant weight and weight of a plant part from equation (6) or (7) If the data for a plant part are directly fed into equation (9), for each set of data, more than one set of values for θ and α can be obtained But by calculating α from equation (6) for total dry matter for each plant its value can be fixed in equation (9) and the correct value of θ can be obtained

Equation (11), which is very similar to equation (9), is suggested by Bleasdale and Nelder[5] to describe the relationship between plant density and plant weight

$$w^{-\theta} = K + \beta\rho^{\Phi} \qquad (11)$$

where θ, K, β and Φ are constants They have substituted a flexible curve given by Richards[6] for the logistic equation of growth, and, as they state "with analogous arguments to those of Shinozaki and Kira" (presumably by employing the law of constant final yield), they have derived their equation. Because of the difficulty in getting correct values of the powers (θ, Φ or α) by fitting the data directly to any equation of this type (equation (9) or (11)), Bleasdale[7] modified equation (11) by taking $\Phi = 1$ The form of this modified equation is similar to that of equation (10)

If the (λ) type logistic equation (equation (1)) is not satisfied the general logistic equation of growth can be employed as the basis for deriving equation (6) In this case the form of the equations (6) or (7) will be modified In most cases, however, addition of one extra term ($C\rho^{\beta}$) to equation (6) can give a close approximation

BOOK REVIEWS

A LONG TIME AGO

The Origin of Life

By J. D. Bernal. (The Weidenfeld and Nicolson Natural History.) Pp. xvi + 345 + 29 plates. (London: Weidenfeld and Nicolson, 1967.) 55*s* net.

THIS book contains the results of a lifetime of thinking by one of the world's most distinguished crystallographers about the nature and origin of life. It presents a highly personal point of view, but it is all the better for that because, in the author's own words, "we are here trying to settle a question of a different character from those of the rest of science; it is not merely a description . . . but an attempt to carry out an intellectual reconstruction based on assumptions of inner logic themselves drawn from experimental science here and now". Biologists have been familiar with these historical exercises since the time of Darwin; not many physical scientists can handle them with the skill and necessary modesty shown by Professor Bernal.

A subject like the origin of life is difficult to treat in any logical order owing to the diversity of relevant evidence, and the book needs to be read as a whole to appreciate the attitude of mind that it displays. We are given "a reasonable, continuous, hypothetical story, a myth of the origin of life" that is consistent with what is known at the present time. Even so, two postscripts are needed in order to mention some very recent discoveries. The underlying philosophy becomes clear in the seventh chapter where, in a brief discussion of the old idea of all new life coming from seeds which are everywhere present, we read: "To my mind it seems to have the same philosophical emptiness to say that life was specially created as to say that it came from somewhere else and that it had been there all the time". It is taken as axiomatic that life arose on the surface of the Earth and that, if life once made itself, it must not be too difficult to make it again if the right chemical and physical conditions can be re-created in the laboratory. This has far-reaching implications on contemporary thought, which are discussed in the last chapter, but the sparkle of an original mind illuminates the whole writing and the thread of ideas is clear. The spontaneity of the chemical processes involved, their great but limited variety and the complexities of their interactions with one another at all levels of organization—these are the underlying concepts that set the pattern for much detailed discussion of what may have happened in the course of the Earth's history.

Bernal acknowledges clearly, by reprinting in full in an appendix, the important articles by Oparin (1924) and Haldane (1929) that started the modern study of the origin of life, but right from his own first major contribution in 1947 he departed decisively from the Oparin scheme in thinking of cells as a late stage in the process, preceded by about 2,000 million years of chemical evolution of macromolecules in "sub-vital areas" not defined by membranous boundaries. Stage I of the story takes us from the formation of the Earth by agglomeration of dust to a "primitive soup" of organic monomers. Much of this has already been reproduced in the laboratory, and the variety of conditions in which amino-acids, nucleotides and sugars can be formed suggests that it has occurred in many places in the solar system, including particularly the body which gave rise to the carbonaceous meteorites. This possibly important source of organic substances is discussed in an appendix by Dr G. Mueller, who stresses that the absence of water and of optical activity distinguishes this synthetic system from its terrestrial counterpart; the much publicized microstructures are dismissed as mineral artifices or terrestrial contaminants. Stage I ended about 5,000 million years ago and so far there is common ground with most other writers on the subject. Stage II, the period of chemical evolution, contains the crucial steps. Polymerization and the genesis of macromolecular order are attributed initially to the condensing properties of mineral particles and there are some intriguing speculations on the role of transition metals as proto-enzymes and of apatite as a primitive phosphate-donating proto-coenzyme. The injection of meteorite-borne organic complexes is mentioned as an example of the type of interaction between separate synthetic patterns that may have played an even greater part later on. Here the element of personal preference enters strongly into the story, and the "alternative pathways to biopoiesis" are listed in the eighth chapter only to be rejected. Perhaps the weakest part of the argument is the author's inability to explain, except by chance, how the key phenomenon of molecular self-replication arose in the course of chemical evolution. He seems to be getting near it in his discussion of "generalized crystallography" and when he writes of "the modification of such replication by selection of molecules, a kind of natural selection which is replaced by the natural selection of organisms at later stages". It is unfortunate that he does not mention a positive suggestion that I myself made in 1953 that branching chain reactions involving phosphate radicals might provide the starting point for such a process of natural selection at the molecular level.

The formation of organelles and the coming together of organelles to form cells is allotted a further 1,000 million years in Stage III, and at some point in Stage III occurred the photosynthetic revolution, the appearance of oxygen in the atmosphere and the first fossils. The chapter entitled "From Molecule to Cell" contains much concise information but little that is new. From then on the story is left to other volumes in this series on "Natural History". The merit of this volume is not only that it bridges the gap between cosmology and biology and so emphasizes the unity of the history of nature, but also that it contains authoritative answers to many questions which must now be asked by every thinking man and woman. Some of these are given concisely in the fourth appendix, others have to be sought in the text. I will select two which are not in the summary. "Is there life on other planets?" Stage I has occurred in many places; Stage II, because it needs water, probably occurred only on the Earth and Mars; Stage III may have occurred only on the Earth. "Is there intelligence elsewhere in the Universe?" "There is a possibility that the oldest and most advanced civilizations on distant stars have in fact reached the level of permanent inter-communication. . . . This is, of course, the wildest of speculations but it has a definite *a priori* probability. For that reason it is not by any means a waste of time to keep on searching and reaching out to see if we can find any trace of intelligences existing." *Chacun à son gout!* Sacrifices to a god in every tree used to be called superstition, not science, but this is a small criticism of what is otherwise a very fine account of an important scientific topic. J. W. S. PRINGLE

MORE LYSENKOISM

Autumnization and its Genetic Interpretation

By Sandor Rajki. Pp. 87. (Budapest: Akadémiai Kiadó, 1967.) 30*s*.

THE author of this work, Sandor Rajki, is the director of the Agricultural Research Institute of the Hungarian Academy of Science at Martonvársár. He is an agricultural botanist, plant breeder and geneticist much concerned with wheat, which is the crop species he discusses in this book He was a student of T D Lysenko, whose continuing influence is very apparent His book is a commentary on work carried out at Martonvársár which is claimed to show that the inheritance of flowering habit can be modified environmentally

Wheat genotypes differ in the environmental conditions they require for the occurrence of flowering So-called "spring" forms flower without any need for exposure to low temperatures or short days, while "winter" forms need such environments as developmental triggers for the initiation of flowering Between the extremes, genotypes can occur in which flower initiation requires environmental stimuli of varying magnitudes The inheritance of the spring–winter habit difference has been studied by a number of workers (for a recent example, see Halloran, G M , and Boydell, C W , *Canad J. Genet Cytol* , 9, 632, 1967) and the chromosomal locations of many of the responsible genes have been determined The chromosomes principally implicated are *2A*, *2D*, *5A*, *5B*, *5D*, *7B* and *7D*, although other chromosomes carry genes of less profound overall effect The inheritance of the character difference is therefore complex but conventionally chromosomal, and its description is well within the compass of current cytogenetics

The essence of Rajki's claim is that when a form of spring wheat, with no low temperature–short day requirement for flowering, was sown in the autumn for a number of successive generations, its genetic constitution was so changed that subsequently exposure to these conditions was essential before flowering would occur Thus a wheat with genetically determined spring habit was changed so that it inherited the acquired character of winter habit One sowing in spring of the form supposedly converted to winter habit is said to be sufficient to cause reversion to spring habit (page 32) It is claimed that the initial stock of spring wheat from which the experiments were started was homozygous and homogeneous, so that the possibility is denied of changes occurring by selection Indeed, Rajki concludes (page 63), "Autumnization, the adequate gradual transformation in the genetically pure spring initial stock corresponding to the quantity and quality of autumn cropping, cannot be acceptably explained through a gene concept denying the inheritance of acquired properties Thus (the category of) mutation is not applicable to autumnization . "

In our laboratory, work has commenced on a genetic comparison of the initial spring form used by Rajki and one of the winter forms supposedly derived from it by autumnization. From this work it appears that the differences are almost entirely attributable to activities of chromosomes *5A*, *5B* and *5D* Differences due to these chromosomes distinguish many spring and winter wheat genotypes, so that there is nothing unusual in the genetic constitution of this winter form Rajki's interpretation would require that the inheritance of the acquired character of winter habit involved allelic changes at a number of well recognized loci and, moreover, the capacity for the reversion to the original allelic state over one generation This notion is in conflict with a vast body of evidence that shows that although mutation occurs it is a random process—the information content of the genetic material being immune from directional change by the environment

There is thus an impasse the only way that Rajki's results can be reconciled with our current knowledge of genetic organization is on the basis of increased mutation rates accompanied by stringent selection The puzzling aspect of the situation is that examples of apparently similar phenomena have been described in flax by Durrant and by Hill in *Nicotiana* In both these cases particular environments are said to have induced specific changes in nuclear inheritance The major and perhaps critical distinction is that the changes Rajki claims to induce involve specific allelic substitutions, whereas in the flax and *Nicotiana* examples such detailed changes cannot be recognized

Despite the availability of examples of analogous work in other genera, most wheat geneticists will continue to have strong reservations on the validity of the autumnization work until it has been repeated outside the sphere of Lysenkoist influence In the meantime, those plant geneticists with a taste for the esoteric, or with a liking for Lysenkoist polemics, are recommended to this volume

RALPH RILEY

SEX CHROMOSOMES

Sex Chromosomes

By Ursula Mittwoch Pp ix+306 (New York Academic Press, Inc , London Academic Press, Inc. (London), Ltd , 1967) 112*s*.

DOCTOR MITTWOCH has written a clear and unambiguous book which will be of interest to many who are not cytogeneticists but seek knowledge in an important field of cytogenetics It will be especially useful to both undergraduate and postgraduate students of human and general genetics, of biology, of medicine and to others interested in genetical problems In each of the sections that deal with different aspects of sex chromosomes, their morphology, behaviour and anomalies in different organisms, the approach is historical· The author has chosen to discuss instructive examples rather than detailed minutiae, while the main objective, that of giving an overall view of the subject matter suited to a particular group of readers, has been kept to the fore

Appropriately a good third of the book is devoted to the sex chromosomes of man and their main abnormalities, and to sex chromatin and its practical and theoretical significance This reflects the fact that, of all vertebrates man is the one in whom most is known about sex chromosomes and their anomalies Also, the sex chromatin, though not actually first discovered in man, has been most successfully exploited in practice in our species and has reopened, with new facts and hypotheses, a fundamental problem of theoretical genetics, namely, that of the mechanisms of dosage compensation of X-linked genes in different groups of organisms Sex chromosomes of other animals are given due consideration, but plants are not neglected.

Melandrium (*Silene*), for example, is well discussed as one organism in which the Y chromosome is a male determiner, as it has recently been found to be in mice and men and other mammals Equal prominence is given to the contrasting type of sex determination in *Drosophila*, based on a balance between autosomes and X chromosomes, to female heterogamety (in lepidoptera and in birds), and to odd chromosomal sex-determining mechanisms

The observations on sex-chromatin formation in female mammals, together with the parallel findings on the time sequence of DNA synthesis of the sex chromosomes and of some autosomes, or their segments, have reopened the whole subject of heterochromatin and heterochromatization The penultimate chapter gives an adequate account of the older views on this difficult subject which arose from a purely cytological description (of a special staining property of some chromosomes or of some of their parts), but has become greatly complicated by a mixture of fact and theory and by the attribution of special properties to the heterochromatic genetic elements In the final chapter, the author synthesizes some of the main observations on sex differentiation in vertebrates and speculates (drawing a parallel also from the work on *Drosophila* on the possible mode of action of the sex chromosomes in sex determination in vertebrates The thesis is that, until primary chemical differences can be demonstrated to underlie early embryonic male or female determination one ought to consider, as has been suggested by others as well, that sex may be determined by a quantitative effect, with possibly a threshold mechanism, brought about "by the agency of relatively large chromosomal regions or even whole chromosomes"

I find that these two necessarily sketchy and speculative chapters, at the end of an otherwise factual book, are useful because they aim to point out important gaps of knowledge and areas where hypotheses abound and where their testing is particularly topical P E POLANI

FURTHER DEVELOPMENTS

Advances in Morphogenesis

Vol 6 Edited by M Abercrombie and Jean Brachet Pp viii+331 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1967) 120*s*

WHENEVER I pick up a book with a title like *Advances in Morphogenesis*, I hope to find that at last someone has found some sort of key to the problem of the link between biochemical and morphological structure Perhaps I am made unduly optimistic by the remarkable advances in our understanding of the nature and functioning of the genetic code in bacteria and viruses characteristic of recent years Needless to say, I am always somewhat disappointed to find that "morphogenesis" is usually taken to mean the development of biochemical diversity, or at most a superficial account of cellular differentiation

With this limitation in mind, however, Abercrombie and Brachet's sixth volume of *Advances in Morphogenesis* is a worth-while addition to the library of anyone interested, not necessarily just in embryology in the classical sense, but in the genetics, biochemistry and physiology of developing animals and plants Indeed, only two articles are concerned primarily with morphogenesis—one by Michael Locke on pattern development in the insect integument, and one by Allsop on heteroblastic development in plants Both are useful and detailed reviews, although the pitiable state of our understanding is well illustrated by a quotation from each author "There is a continued need to recognize that the terms used in this description may have no reality in the phenomena being studied We can proceed no further until some structural, physiological, or biochemical correlation has been made" (Locke, page 82), or "There is also no conclusive evidence that physiological ageing is determined by any intrinsic ageing of the mature tissues of the plant A plausible explanation of these changes invokes a regulatory effect of the intracellular environment on gene activity But it is not even certain that changes in gene activity are necessary" (Allsop)

Astaurov's paper on cytogenetic mechanisms in silkworms is more an assessment of the relative roles of nucleus and cytoplasm in development, and various modes of parthenogenesis, than a genuine attack on problems of morphogenesis Interesting as it is, I feel that it could have been somewhat compressed without loss It contains, however, detailed descriptions of methods which could be useful to the experimenter

Wilt's article on embryonic haemoglobin synthesis, and Wischnitzer's on the ultrastructure of the amphibian egg, are neither of them strictly concerned with morphogenesis Both are very adequate reviews, and the latter is beautifully illustrated, but whether this volume is really the proper place for their publication is perhaps doubtful

"The Biology of Teratomas", by Leroy Stevens, interested me particularly, largely because it directs attention to what was to me an unusual realm of embryological investigation That primordial (male) germ cells may be able to give rise to almost all kinds of tissue in a teratoma, even if in a disorganized way, must surely have significance in relation to the ordered development of the normal embryo

Finally, L. Gallien's account of sexual organogenesis, in both invertebrates and vertebrates, is an admirable summary of advances in our knowledge of sex-determination, especially in relation to endocrine control in invertebrates. Whether the clarity of this article derives from the original French or in part from the excellent translation, it leaves a lasting impression of how good a review article can be MICHAEL BEGG

GEOLOGY OF FOLDS

Structural Geology of Folded Rocks

(Rand McNally Geology Series.) By E H Timothy Whitten Pp. xiv+663 (Chicago Rand McNally and Company, 1966) $10 50

THE crust of the Earth has had a complex deformation history as a result of past orogenic disturbances. Great advances have been made in recent years in the understanding of the fracture patterns and folded forms taken up by stratified rocks during these deformations Professor Whitten's book describes the morphology of folded rocks and structures associated with folds It aims at guiding the reader through the modern literature, much of which is scattered through a number of specialist journals, and synthesizing these data.

The appearance of the book is immediately attractive, and departs radically from many traditionally oriented texts on structural geology now available The production is excellent and the publishers are to be congratulated on the way that they have reproduced the many figures, maps and photographs The text, however, is disappointing, the writing is verbose and repetitive, and several chapters are heavily weighed down with jargon Although Professor Whitten has been industrious in his incorporation of the results of others, in his compendium of data there is often an unfortunate lack of critical discussion as to their significance This book purports to be a synthesis, but a collection of data must be integrated into some logical system before it deserves this description Rarely does the author arrive at firm conclusions or offer to pass on to the reader his own experience in any personal commitment In discussions on controversial matters (for example, the significance of foliation, page 263) he gives no clear summaries of the various alternative working hypotheses that may explain the facts

The book is profusely illustrated, of the 485 figures more than 80 per cent have been published before It is most useful to have all these illustrations together in one book, but it is a pity that their integration into the text is sometimes so poor For example, although Professor Whitten has set out to base his account of folds on actually described field relations, there seems little justification for reproducing eighty-four small field sketches of folds (Figs 182, 183 and 184) when they are discussed in only two sentences in the text Professor Whitten's original contributions to the illustrative material are mostly confined to stereographic and equal-area-projections of geometrical forms, and some simple and rather unrealistic maps showing the geology of hypothetical regions Where original diagrams have been included in the sections on slip folds (Figs 110 and 112) and superposed folds (Figs 302 and 303) the presentation of the complex three dimensional geometrical properties is so ill conceived that I seriously doubt their usefulness

Griffiths has claimed that "progress in science can generally be measured by the degree in which the subject is pervaded by mathematics" Professor Whitten supports this assertion, yet he provides no summary of the analytical methods which have been used during the past two decades and which have revolutionized our understanding of the development of rock structures. In the preface he excuses himself for making no reference to the physical aspects of rock deformation, or to the mechanical properties of rock under stress. This admission precludes any subsequent discussion of the reasoned syntheses on fold formation put forward by Biot, Ramberg and others. His description of stress, strain and the deformation process is hardly adequate to do justice to recent interpretations of the formation of minor structures in deformed rocks. Criticisms of a book on the grounds that it omits certain aspects of the subject might be regarded as unfair, but this work purports to be a modern synthesis and these omissions are a serious flaw.

Many fundamental definitions of the geometrical characteristics of folds presented are at variance with those generally accepted. Taking a specific example from the second chapter, Professor Whitten's definition of cylindroidal folds (page 40) is weak and typical of the style of many sections of his work. "if enough points on the folded stratum are observed, some will be found to coincide with most parts of a cylinder". The fundamental parameters of fold wavelength and amplitude are nowhere described, and Professor Whitten gives an extremely confused exposition of the axial-surface and bisecting-surface of a fold. He correctly defines the bisecting surface (page 40) as that which bisects the fold limbs and uses a figure (unacknowledged Fig. 4–18 from Turner and Weiss, *Structural Analysis of Metamorphic Tectonites*) to illustrate that this surface need not coincide with the axial surface. If the reader returns to an earlier section of the book (pages 6–8, Fig. 4) where the term bisecting plane of the fold limbs is first introduced it will be apparent that Professor Whitten (i) has not bisected the fold limbs to derive this plane, he has drawn the axial surface of the fold, and (ii) has misidentified the trace of the bisecting surface by drawing the line representing the projection of the hinge line of the fold in stratum α on to the horizontal plane.

The terms competent and incompetent are used by the geologist to describe the relative ductility of different rock materials. Professor Whitten re-defines these terms, competent layers develop folds of large amplitude whereas incompetent ones accommodate themselves to the spaces between the competent layers. The dimensions of a "large amplitude" are never specified, and it seems apparent that if adjacent competent and incompetent layers are found together in a harmonically formed fold, they will both show the same fold amplitude. One could proceed chapter by chapter through this book finding inaccurate definitions and illogical development. Structural geology is one aspect of Earth Science which is ideally suited to the development and application of analytical techniques. In the past so much work in this field has been entirely descriptive that any new book, if it is to have real value for present students, must surely encourage clarity of thought and precision of definition. At first sight Professor Whitten's book might seem to do this, but I find it entirely in sympathy with the older attitudes.

As well as being marred by poor explanation of the fundamental geometrical features of folds, this book also presents some incorrect analyses when describing the geometrical forms of more complex structures. For example, the section describing the effects of flexural slip folding on sediments with cross lamination (pages 522–526) is based on the faulty assumption that the dihedral angle between the inclined beds remains constant during folding. Later in this section Professor Whitten does note that this angle will change during folding, but he makes no comment as to how this might invalidate his previous solution to the problem.

Superimposed folding has been neglected in many previous textbooks on structural geology. Professor Whitten has remedied this defect and devoted nearly a quarter of his text to a discussion of the subject. He has adopted Sander's classification, $B_1 \perp B_2$ (penecontemporaneous and perpendicular fold axes) and $B_1 \wedge B_2$ (unrelated and inclined fold axes) as a framework to his descriptions. He never establishes the reasons why penecontemporaneously developed fold axes need be perpendicular or describes the strain states which can lead to synchronous folding in several directions. All field workers are agreed that the timing of the development of superimposed folds can vary greatly, but Professor Whitten gives no indication of the criteria by which the field geologist determines these age relationships. Contradictory statements on the nature of $B_1 \wedge B_2$ fold geometry are given, the geometrical relationships being described as "very complex" on page 327 and "relatively simple" on page 329. Professor Whitten illustrates the geometry of superposed flexural slip folds with a detailed investigation of a hypothetical area and makes the deduction that the later fold axes lie in a plane normal to the compression. He never defines what he means by compression in terms of stress or strain and he ignores Ramberg's (*Norsk Geol. Tid.*, 1959) and Flinn's (*Quart. J. Geol. Soc.*, 1962) pertinent studies on fold axis orientation in buckled layers which do not accord with his own deductions on this orientation. The chapter on "Examples of Superposed Folding" begins with 113 pages of illustration of the second ($B_1 \wedge B_2$) of his and Sander's two types of superposed folds. He follows this with a section of only four pages examining described instances of the first type ($B_1 \perp B_2$) most of which he suggests are not convincing examples and concluding that ". . . it is not common to find inequivocal description of $B_1 \perp B_2$ folds". The difficulty that Professor Whitten experiences in finding well documented examples of $B_1 \perp B_2$ folds leads to his comment, "This unsatisfactory situation should be viewed as a challenge to field geologists". I think that this "unsatisfactory situation" should have led the author to re-examine the validity and usefulness of Sander's classificatory scheme, and not to accept it as some kind of irrefutable dogma to which the geologist has consciously to seek out supporting evidence.

Much of Professor Whitten's own research has been centred on developing statistical techniques for determining the significance of modal analysis in coarse grained igneous rocks. As reviewer of this book I looked forward to reading the chapter on "Models and New Methods for Quantitative Fold Description" to see how his techniques might be applied in structural geology. This chapter proved a complete disappointment; what little it has to say is obscured by a mass of verbose writing and technical jargon. The geologist is extorted to "structure" his initial hypotheses into "conceptual process-response models" and eventually to evolve these into "a deterministic model in which all relevant response characteristics are incorporated into a unifying mathematical equation". Professor Whitten describes how statistical analysis has been used to describe the shapes of single folded layers and then proceeds to analyse the regional variability of these shapes within a hypothetical area by the methods of trend surface analysis. If he had applied these methods to the naturally deformed rocks illustrated in earlier sections of his book, he would have discovered their limitations, the separate layers in a single fold will practically always have different shapes, and so it will be impossible to establish a single set of statistical parameters characteristic of the folds at any one locality.

To summarize, this book is an uncritical compilation of some of the significant researches into the geometrical forms of folded rocks. It is often wordy, yet makes little attempt at reasoned syntheses of the many works from which it quotes. Because it ignores so much of the analytical development that has been made in the studies of folds during the past twenty years, it is my view that the book is unbalanced and dated in its approach. It is, however, well illustrated and does offer a good visual compendium on the variations of the forms of folded strata to those geologists who do not have ready access to the original descriptions.

J G RAMSAY

HAMILTON'S PRINCIPLE

Hamilton's Principle and Physical Systems

By B R Gossick. Pp xiii+247. (New York: Academic Press, Inc., London: Academic Press, Inc (London), Ltd, 1967.) 68s.

MOST books on classical mechanics discuss the Lagrangian formulation of mechanics and then usually include a demonstration that Lagrange's equations can be derived from Hamilton's principle. Although it is often stated that problems of electrical systems can be expressed in a similar mathematical form this is not usually developed at any length in such books.

The author of this book is anxious to provide a text giving a treatment of mechanical and electromagnetic systems which emphasizes the similarity of approach used in dealing with problems arising in both. In brief he attempts to do this by giving a general form of Hamilton's principle and using this to provide the appropriate framework for a discussion of the mechanical and electrical examples selected in the book.

There are six chapters. The first consists of a three page historical introduction. The second provides a background of mathematics (mostly concerned with Fourier series and Laplace transforms) which is used from time to time in later chapters.

The third chapter discusses the calculus of variations and gives an account of Hamilton's principle for general physical systems. The theory is given a concrete interpretation in the fourth chapter where conservative mechanical and electrical systems are considered.

The fifth chapter, which constitutes a third of the book, deals with non-conservative linear systems. The only mechanical system treated here (which occupies two pages) is that of a rigid body with damping. The last chapter deals with the Lagrangian density.

The author claims in the preface that a comprehensive and elementary presentation of mechanical and electromagnetic systems is given. Students unfamiliar with the material will not find this a suitable text. The presentation is not self-contained and is incomplete. For example, when the Euler angles for a rigid body are introduced in the fourth chapter the only explanation is a diagram which would be unintelligible. On the other hand, for those with an appropriate background of physics a considerable part of the book is redundant.

In view of the length and emphasis of the fifth chapter and a comment in the preface that the application of Hamilton's principle to non-conservative linear systems has not previously appeared in other texts it seems reasonable to suppose that this chapter is the main reason for the appearance of the book.

Although the book is well printed and clearly set out, I find it difficult to suggest what class of readers would find it of greatest value.

M J WILFORD

TESTING IN SCHOOLS

Teachers and Testing

By David A Goslin. Pp xix+195. (New York: Russell Sage Foundation, 1967.) $7.50.

THE supposed advantages and alleged deficiencies of intelligence and objective achievement tests (forced multiple-choice, true/false, matching, completion, and so on) have been widely debated. Less attention has been paid to the immediate social context in which such tests are given: particularly to how schools and teachers use tests, and are themselves influenced by them. This book reports a well-conducted survey of these sociological aspects of testing. Although American, it should be of relevance and interest to teachers, testers and education policy makers in Britain. American children average three standardized tests every year of their schooldays. If we are following this trend, we should pay attention to how it will affect our schools and teaching.

A large sample of public secondary school teachers, counsellors and pupils received questionnaires covering a wide range of issues: beliefs about tests, teachers' psychometric sophistication, the intended and actual use made of tests in selection, grading and vocational guidance, the dissemination—or lack of it—of test scores, the extent to which pupils are pre-trained for testing, the weight of test scores in evaluation, and so on. Numerous summary tables accompany the text but are not always adequately summarized within it.

Despite the thoroughness of the investigation there are three methodological deficiencies. First, in this type of work the interesting questions often emerge only after quantities of data have been collected. A pilot study would have enabled subsequent concentration of resources and treatment of pertinent issues in greater depth. Second, there is little said about how subjects perceived the investigation, although the author himself acknowledges the extent of extraneous social influences on expression of opinion. It is not clear, for instance, whether or not teachers thought their personal views on testing might filter back to their employers. Third, there is reliance almost entirely on self-reported questionnaire data. The one exception was an interesting experiment—using made-up school records—to see what weight teachers attached to test scores in contrast to other recorded information, in placing pupils in *A* or *B* streams. There was a marked disparity between teachers' reports of what they generally do, and what they did in the experiment. It pinpoints the weakness of over-reliance on questionnaires and the need for more imaginative and realistic methods of investigation. It also undermines confidence in the rest of the study. The author describes other points of dissonance and disagreement that seem to reflect an underlying sense of uncertainty among teachers about the place of testing in their work. There are many examples. Of those teachers who strongly advocate letting their pupils have a general indication as to their IQ, a quarter had never given their pupils any such information. The number of tests a school gives, and its stated test policy, are unrelated to how much actual use is made of test results in the school. Teachers generally want to withhold test scores from parents, while parents urgently want to know them.

Two major effects of testing on teaching are mentioned, but too briefly and peripherally for their importance. First, despite their protestations to the contrary, it was found that teachers do often coach pupils for tests. Moreover, the more schools are oriented towards college admission, the more likely they are to give such preparation and assistance. The chances of going to college for pupils in other schools may therefore be affected. The second major effect is on the school's own examining, where the multiple-choice form of question has replaced other forms, such as the essay. It is conceivable that this predominance may lead to students being rewarded for achieving complete coverage of the syllabus, rather than for exercising their individuality in selection and expression. The way in which exams impose their own constraints and patterns on teaching, learning and subsequent intellectual development needs to be further investigated. The dog should wag the tail, and not the tail wag the dog.

MALCOLM PARLETT

OBITUARIES

Dr H. R Nettleton

Harold Redmayne Nettleton, who died on December 19, 1967, in his eighty-fourth year, was a distinguished exponent of classical physics in both teaching and research

He took his London B Sc from Leeds in 1903 and was appointed in 1906 as an assistant lecturer at Birkbeck College, where he took his M Sc in 1916 and D Sc in 1922

The raising of the status of the college to that of a School of the University of London in 1920, and the consequent establishment of chairs and readerships, owed much to the scholarly labours of a small band, among whom Nettleton was notable At this time his researches were largely on the determination of thermal conductivities of liquids and on the Thomson effect He continued to be active in research during the professorships of P. M S Blackett and of J D Bernal, turning his attention latterly to the absolute determination of electrical resistance, here he devised and carried out, with very modest facilities, an elegant commutating d c. method, similar in some respects to that subsequently used by the US National Bureau of Standards. In one of his last papers, published jointly with the late Professor S Sugden in 1939, on the magnetic susceptibility of nickel chloride, he described a simple method, still too little known, for the accurate measurement of magnetic fields.

A keen chess player and cricketer in his day, and an ardent champion of women's suffrage, he was devoted to Birkbeck College, which he served actively until his retirement as senior lecturer in 1952 During the Nazi period, he was a friend of the scholars who found a refuge at Birkbeck, and to generations of Birkbeckians a father confessor, a role in which he triumphed over formidable deafness But, above all, he will be remembered by his students for his superb lectures, minutely prepared and constantly revised, which delighted as much by their clarity and by their apparent ease as by their nice touches of humour, delivered with dry seriousness.

Both his students and his colleagues drew inspiration from his aesthetic flair for rational experimental design and from his absolute scientific integrity. Giving up active physics on his retirement, he kept to the very end his interest in current affairs and in friendship, which he cultivated with the same devotion and attention to detail that characterized his scientific work He will be widely missed

W Ehrenberg

University News : London

Dr M G M Jukes, lecturer in the University of Edinburgh, has been appointed to the chair of veterinary physiology tenable at the Royal Veterinary College The title of professor of botany has been conferred on Mr P R Bell in respect of his post at University College

Appointments

Mr James Ian Smith, under-secretary in the Department of Agriculture and Fisheries for Scotland, has been appointed a member of the Agricultural Research Council in succession to the late Mr Ralph Hamilton Law

Mr J A Nelder, of the National Vegetable Research Station, has been appointed head of the Rothamsted Experimental Station's Statistics Department in succession to Dr F Yates

Meetings

Problems of the Pebble Bed and Granular Materials, March 6–7, Nuclear Research Establishment, Julich (Dr D Bedenig, Brown Boveri/Krupp Reaktorbau GmbH, Experimentelle Entwicklungsabteilung, Postfach 589, D-517 Julich, Bundesrepublik Deutschland)

Theoretical Mechanics Colloquium, April 2–5, University of Oxford (Colloquium Secretary, Dr A. B Tayler, Mathematical Institute, St Giles, Oxford).

Recent Developments in Flame Physics, April 30–May 1, Department of Chemical Engineering and Chemical Technology, Imperial College (Professor F J Weinberg, Department of Chemical Engineering and Chemical Technology, Imperial College, Prince Consort Road, London, SW7)

Fluidics Conference, May 8–10, Torino (Mr H Stephens, British Hydromechanics Research Association, Cranfield, Bedford)

Precision Electromagnetic Measurements, June 25–28, National Bureau of Standards Laboratories in Boulder, Colorado (Mr Donald D King, Aerospace Corporation, PO Box 95085, Los Angeles, California).

Chemistry of Natural Products, July 8–13, London (The Secretary, 5th International Symposium on the Chemistry of Natural Products, c/o The Chemical Society, Burlington House, London, W1).

Competing Spectrochemical Techniques, July 10–12, University of Keele (The Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London, SW1).

Electrical Contact Phenomena, July 15–18, University College of Swansea (The Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London, SW1)

Photobiology, August 26–31, Dartmouth College, Hanover (The Secretariat, Vth International Photobiology Congress, Argonne National Laboratory—202, Argonne, Illinois)

Problems of Cooley's Anaemia, September 9–11, New York City (Dr H Fink, Cooley's Anaemia, Coney Island Hospital, Brooklyn, New York, NY 11235)

Volcanoes and their Roots, September 7–9, 1969, University of Oxford (Dr J D. Bell, Department of Geology and Mineralogy, Parks Road, Oxford)

Erratum The communication "Electrophoretic Study of Glutathione Reductase in Human Erythrocytes and Leucocytes", which appears on page 256 of this issue of *Nature*, is by Jean-Claude Kaplan and Ernest Beutler, and not only by Jean-Claude Kaplan as stated at the end of the article

Erratum In Table 2 of the article "*In vitro* 'Lipid' Metabolism in the Developing Human Foetus" by Jacques F Roux, A Grigorian and Y Takeda (*Nature*, 216, 819, 1967), the figures under the column headed "Brain" should read 100, 300, —, 340 and 720.

Erratum In the communication "Kinetics of Association of Carbon Monoxide with Haemoglobin at Low Temperature" by R Banerjee, P Douzou and A Lombard (*Nature*, 217, 23, 1968) the second and third sentences of the sixth paragraph on page 24 should read "The value of this constant, which we shall call l'_4, is found to be 7×10^3 M^{-1} sec^{-1} at $-55°$ C This is not far from what would be expected from Gibson's value of 6 9×10^6 at 19° C and activation energy (10 kcal) determined in aqueous solution"

Erratum. In the communication entitled "Detection of an Anisotropic Soft X-ray Background Flux" by C S Bowyer, G. B Field and J E Mack (*Nature*, 217, 32, 1968) the formula in line 14 of the penultimate paragraph should read $\int N_e{}^2\,dl = 0\ 7$ and not $\int N_a{}^2\,dl = 0\ 7$

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, January 22

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 10 a m—Colloquium on "Microwave Integrated Circuits", "Microwave Solid State Sources"

Institute of Actuaries (at Staple Inn Hall, High Holborn, London, WC1), at 5 p m—Mr H A R Barnett "A Theory of Mortality"

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m—Discussion Meeting on "Microwave Electrostatic Wattmeter", opened by Professor H E M Barlow, FRS

University of London (in Lecture Theatre A, Mechanical Engineering Building, Imperial College of Science and Technology, Exhibition Road, London, SW7), at 5 30 p m—Professor Bertil Matern (Roval School of Forestry, Stockholm) "Statistical Models of Two-Dimensional Variation" (further lectures on January 24 and 26)

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m—Mr W B Gosney "Modern Refrigeration" (First of three Cantor Lectures Further lectures on January 29 and February 5)

Tuesday, January 23

University College London (in the Anatomy Theatre, Gower Street, London, WC1), at 1 20 p m—Dr W G Chaloner "Evidence of Life in Meteorites" *

Imperial College of Science and Technology (in Lecture Theatre A, Department of Mechanical Engineering, Exhibition Road, London, SW7), at 5 30 p m—Professor K F Roth, FRS "The Large Sieve" (Inaugural Lecture)

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m—Discussion Meeting on "The Importance of Cleanliness in Power Plant Erection"

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, SW1), at 6 p m—Professor A M North "The Effect of Polvmer Chain Flexibility on the Rates of Fast Macromolecular Reactions"

Society for Analytical Chemistry, Special Techniques Group (joint meeting with the Polarographic Societv at Imperial College, South Kensington, London, SW7), at 6 30 p m—Meeting on "Stripping Techniques" Speakers Mr B Fleet and Mr P Kane

Wednesday, January 24

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m—Mr F G Taylor and Mr J D S Hinchcliffe "Cables for Aircraft—Design and Development", Mr P W C Jones "Cables for Aircraft—Installation Systems and Experience", Mr R F Brazier "Cables for Aircraft—Pressure-Type Connections"

Challenger Society (at the Linnean Societv, Burlington House, Piccadilly, London, W1), at 5 45 p m—230th Scientific Meeting Mr P R Walne "Artificial Cultivation of Shell Fish" (Buckland Lecture)

Institution of Electronic and Radio Engineers, Telecommunications Group (at 8–9 Bedford Square, London, WC1), at 6 p m—Mr G Parker "Studio Colour Equipment"

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m—Dr G E R Deacon "Progress in Ocean Technologv" (Thomas Lowe Gray Lecture)

Society of Chemical Industry, Food Group—Nutrition Panel (joint meeting with the Oils and Fats Group, at 14 Belgrave Square, London, SW1), at 6 15 p m—Dr A Gorton "Some Biochemical Aspects of Oils and Fats"

Society of Environmental Engineers, Packaging Group (at the Euston Tavern, 73 Euston Road, London, NW1), at 6 30 p m—Mr J Raeburn "Containerization, a New Environment for the Packaging Engineer"

Thursday, January 25

Fertilizer Society (at the Geological Societv, Burlington House, Piccadilly, London W1), at 2 30 p m—Professor E W Russell "The Place of Fertilizers in Food Crop Economy of Tropical Africa"

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m—Discussion Meeting on "Electrical Propulsion for Space Vehicles"

Institution of Mechanical Engineers, Automatic Control Group, and the Control and Automation Division of the IEE (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m—Discussion Meeting on "Orientation Control of Large Structures"

Thursday, January 25—Friday, January 26

Challenger Society and representatives from the Marine Laboratories (Natural Environment Research Council Scheme) (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, SW7)—Scientific Papers

Friday, January 26

British Biophysical Society, Physical Biochemistry Group (at the Laboratories of the Chester Beatty Research Institute, Clifton Avenue, Belmont, Sutton, Surrey), at 11 a m—Meeting on "Zonal Centrifugation—Its Application to the Isolation of Macromolecules, Viruses and Sub-Cellular Organelles"

Colour Group (Great Britain), Photobiology Group (at the Middlesex Hospital Medical School, London, W1), at 2 p m—Meeting on "New Light Sources for Photobiology"

Saturday, January 27

Inner London Education Authority (at the Hornlman Museum, Forest Hill, London, SE23), at 3 30 p m—Mr Stanley Cramp "An Ornithologist in Jordan" *

Monday, January 29

Institution of Electronic and Radio Engineers, Joint IEE/IERE Medical and Biological Electronics Group (at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 6 p m—Colloquium on "Diathermy"

Institution of Mechanical Engineers, Medical Engineering Working Party (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m—Discussion Meeting on "The Physics and Medical Applications of Lasers"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Temporary Assistant Lecturer or Lecturer in the Department of Engineering in the field of geotechnology—The Registrar, The University, Leicester (Januarv 22)

Assistant Lecturer in the Department of Philosophy—The Registrar, The University, Leicester (January 26)

Technician (with experience in general histological techniques and at least HNC or equivalent) for the Histology Laboratory—The Secretary, Houghton Poultry Research Station, Houghton, Huntingdon (January 26)

Lecturer in the Department of Mathematics to be responsible for the teaching of statistics to social scientists—The Registrar, The University, Nottingham (January 29)

Lfcturer or Assistant Lecturer (with a special interest in protein crystallography) in Crystallography—The Secretary, Birkbeck College (University of London), Malet Street, London, WC1 (January 29)

Temporary Lecturer/Senior Lecturer (with a good honours degree or Dip Tech or equivalent in mathematics, and preferably some teaching experience) in Mathematics at Britannia Royal Naval College, Dartmouth, Devonshire—Ministry of Defence, Navy Department CE1(N), 368 Old War Office Building, London, SW1 (January 29)

Lecturer (with initial qualifications in either physics, mineralogy or chemistry, with experience of, or interest in, the application of modern techniques to soil studies) in Soil Science—The Secretary, The University, Aberdeen (February 3)

Chief Technician in the School of Biological Sciences to take charge of the Teaching Laboratories of the School, duties will include the supervision of technical staff, the requisitioning of supplies and assisting in the organization of practical classes—The Laboratory Superintendent, School of Biological Sciences, University of East Anglia, University Plain, Norwich, NOR 24B (February 5)

Senior Lecturer (I) or Lecturer (II) in the Department of Histology—The Registrar, The University, Liverpool, 3, quoting Ref RV/305/N (February 7)

Chair of Physics at Chelsea College of Science and Technology—The Academic Registrar (A), University of London, Senate House, London, WC1 (Februarv 9)

Junior Research Fellowship without restriction of subject—The Secretarv, Merton College, Oxford (February 10)

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Liverpool, quoting Ref RV/236/N (February 10)

Research Fellowship in Science subjects (including Mathematics and Engineering)—The Secretary of the Fellowships Committee, Trinity Hall, The University, Cambridge (February 15)

University Lecturer in Physiology—The Deputy for the Waynflete Professor, University Laboratory of Physiology, Oxford (February 15)

Second Chair of Applied Mathematics—The Registrar, The University, Newcastle upon Tyne (February 17)

Chair of Geography—The Registrar, The University, Sheffield (February 19)

Senior Lecturer or Lecturer in Psychology in the Department of Philosophy, University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, WC1 (February 20)

Senior Lecturer/Lecturer Grade I in Diagnostic Pathology, a Senior Lecturer/Lecturer Grade I in Morbid Anatomy and Histopathology, a Lecturer Grade I in Chemical Pathology, and a Lecturer Grade I/Lecturer Grade II in Clinical Chemistry at the College of Medicine of the University of Lagos—The Inter-University Council, 33 Bedford Place, London, WC1 (February 28)

Wayne Kerr Chair of Measurement Science with particular reference to Electrical Metrology—The Academic Registrar (LFG), University of Surrey, Battersea Park Road, London, SW11 (March 1)

Chair of Bacteriology—The Registrar, The University, Senate House, Bristol, 2

Assistant Professor (with training and experience in the genetics of micro-organisms, particularly in fungal genetics) in the Department of Botany—Dr C J Hickman, Department of Botany, University of Western Ontario, London, Ontario, Canada

Associate Professor (science or medical graduate with a Ph D in biochemistry, and several years of teaching experience) of Biochemistry—Professor P H Jellinck, Head, Department of Biochemistry, Queen's University, Kingston, Ontario, Canada

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13 10 0**
6–11	**£12 15 0**	**$44 50**	**$48 30**	**£12 15 0**
12 or more	**£12 0 0**	**$42 50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A)

Slabs get better results!
And they're just plain easier to use.

In polyacrylamide gel electrophoresis, your choice is between flat gel slabs and cylindrical "discs." Here are seven reasons why you may prefer using slabs:

1 Slabs yield more accurate comparisons Because conditions are identical across all slots Same gel, same temperature, same voltage.

2 Slabs permit confident replication For the same reason.

3 Slabs don't require special densitometers. No meniscus, no third-dimension complications

4 Slabs may be destained rapidly without artifacts, Because they're flat.

5 Slabs make two-dimensional electrophoresis possible Also because they're flat.

6 Slabs take less time to prepare One mold takes the place of all those individual tubes

7 Slabs allow both continuous and discontinuous gel and buffer systems.

If you're merely checking the purity of a protein, the unevenness of cylindrical "discs" may be unimportant But if quantitation and accurate comparison are among your basic goals in electrophoresis, you'll probably do better with flat slabs

We'd like to help you choose rationally. Just call us collect and talk it over. Ask our Technical Service at (215) 382-9100 Or write for detailed information on "Vertical Gel Electrophoresis" E-C Apparatus Corporation, 755 St. Marks Street, University City, Philadelphia, Pa. 19104.

BIOCHIMICA ET BIOPHYSICA ACTA

BIOENERGETICS

ELSEVIER'S JOURNAL DEVOTED TO FUNDAMENTAL RESEARCH INTO THE ENERGY-RELAY PHENOMENA OF BIOCHEMISTRY –

Biological oxido-reduction reactions - oxidative phosphorylation - photosynthesis - contractile and motile systems

The following sample of forthcoming papers illustrate the scope of this section of BBA

Oxidative phosphorylation in brown adipose mitochondria, R J Guillory and E Racker (Ithaca, U S A)

On coupling factors of oxidative phosphorylation, R H Vallejos, S G van den Bergh and E C Slater (Amsterdam, The Netherlands)

Studies on the respiratory chain-linked reduced nicotinamide-adenine dinucleotide dehydrogenase I Effect of diethyl ether on particulate NADH dehydrogenase, Z Kaniuga, A Gardas and M Jakubiak (Warsaw, Poland)

Induction of respiratory deficiency by repression of the respiratory system in a mutant of *Saccharomyces cerevisiae*, T Negrotti and D Wilkie (London, Great Britain)

ESR of non-haem iron in xanthine oxidase, J F Gibson and R C Bray (London, Great Britain)

Light-induced electron transport in Chromatium strain D, M A Cusanovich and M D Kamen (La Jolla, U S A)

Interactions between photosynthesis and respiration in Chlorella I Types of transients of oxygen exchange after short light exposures, A Ried (Stanford, U S A)

Protochlorophyllide aggregation in solution and associated spectral changes, C J Seliskar and B Ke (Yellow Springs U S A)

Rapid publication
World-wide circulation
Available as a part subscription of BBA

Subscription details for 1968
Biochim Biophys Acta, Vols 153, 162 (B3, B4), 8 issues, total price US$ 36 00, Dfl 130 00 Airmail surcharge for USA and Canada US$0 80

APPOINTMENTS VACANT

LONDON BOROUGH OF ENFIELD EDUCATION COMMITTEE

ENFIELD COLLEGE OF TECHNOLOGY QUEENSWAY, ENFIELD, MIDDLESEX

(Proposed Polytechnic)

Principal G S Brosan, T D, Ph D

FACULTY OF ARTS (Ref A 8)

Suitably qualified and/or experienced **Lecturer** or **Assistant Lecturer** in Social Science/Technology required to teach and develop a course in Technology on the B.A Business Studies and the Fundamentals of Accounting Courses The course is intended to provide an appreciation of the influence of technological developments on business activity The person appointed will have access to assistance from both Arts and Technology Faculties Salary Assistant Lecturer Grade B £955 to £1 845, Lecturer, £1,875 to £2 140, plus London Allowance of £70 per annum

Applicaton forms and further details from the Academic Registrar, to whom completed forms should be returned within two weeks

D B DENNY, M A,
Chief Education Officer
(201)

THE UNIVERSITY OF SUSSEX

ASTRONOMY CENTRE

RESEARCH APPOINTMENT

Applications are invited for a post in a research group in theoretical astronomy working mainly in problems of stellar and galactic evolution The group is supported by the Science Research Council and forms part of the Astronomy Centre of the University of Sussex The appointment will be for two years in the first instance, it will carry the status of Lecturer in the University and the starting salary will be at a point in the lecturers' scale, £1,470 to £2,630 per annum, depending upon the qualifications of the person appointed He should be prepared to start work not later than October 1, 1968

Applications (four copies), giving full curriculum vitae and the names of two referees, should be sent before January 31, 1968, to the Assistant Registrar (Establishment), the University of Sussex Essex House, Falmer, Brighton BN1 9 QQ quoting Ref 870/2 (220)

SCOTTISH HORTICULTURAL RESEARCH INSTITUTE

INVERGOWRIE, DUNDEE

BIOCHEMIST/VIROLOGIST

to study the biochemical behaviour of plant viruses (especially tobacco rattle virus) in tissues Experience of handling nucleic acids desirable, research experience of plant viruses not essential The appointment will be offered at the Scientific Officer or Senior Scientific Officer level and a first- or second-class Honours degree is the minimum qualification Salary scales S O £926 to £1,547, S S O, £1,744 to £2,155 Superannuation under F.S.S U

Further particulars may be had from the Secretary, with whom applications, giving age and full details of education and experience, together with the names of two referees, should be lodged by February 14 (259)

Pharmacologist

Major Pharmaceutical Company with research facilities located in Montreal, Canada, has an attractive career opportunity in Pharmacology.

THE JOB

To initiate and/or develop screening and follow-up procedures in animals in order to discover new types of drugs for treatment of functional and degenerative respiratory disorders in man The ability to provide leadership to a supporting staff of 3-4 is essential

THE MAN

Young man with training in Pharmacology to the Doctorate level Some experience in industry or work under a Post-Doctoral Fellowship in the area of respiratory disorders a real advantage

BENEFITS

Top Canadian salary and growth potential Comprehensive health, life insurance and retirement plan as well as paid passage to Canada

You are invited to explore this opportunity in complete confidence Applications should be made promptly by air mail to

The Director of Research, Merck Frosst Laboratories,
P.O. Box 1005, Montreal 3, Quebec, Canada.

CANCER INSTITUTE—AUSTRALIA

(PETER MACCALLUM CLINIC)

STATISTICIAN

The Cancer Institute Board in association with the University of Melbourne, invites applications for the position of Statistician for research and consulting work

The Board proposes to establish a Statistical Unit to advise its research staff on statistical aspects of their work, to investigate questions of design and interpretation of clinical data, and to carry out general statistical investigations The Statistician will be the head of the Unit and the first Officer appointed

In addition to his duties at the Clinic of the Cancer Institute, the Statistician will be given the opportunity to work in the Department of Statistics at the University of Melbourne This work may include research in statistical theory, some lecturing on topics related to his particular interests, and the supervision of research students, particularly those working in related fields

QUALIFICATIONS Ph D or equivalent qualification in statistics Some research experience in the biometrical field would be an advantage

SALARY Depending on qualifications and experience, in the range $8,000 to $10 000, within the range for Senior Lecturer or Reader in the University of Melbourne

GENERAL CONDITIONS Superannuation (equivalent to F S S U) and generous long service leave annual leave and sick leave provisions are included
An overseas appointee will be granted first-class fares for himself and family, together with a removal allowance of $400 for furniture and personal effects

Further particulars may be obtained from the undersigned at 278 William Street, Melbourne, Victoria, 3000, Australia, with whom applications close on February 29, 1968

R K Churches, *Manager and Secretary*
(214)

SCIENTIFIC EDITORS

Unique opportunities have arisen for suitably qualified people to work as Editors in the Central London office of a leading technical publisher We are one of the world's leading publishers of scientific literature documentation and we invite applications from people who are qualified in one or more of the following

BIOCHEMISTRY • PHYSIOLOGY • PHARMACOLOGY
PHARMACEUTICAL OR AGRICULTURAL CHEMISTRY

Previous editorial experience is not essential, but some knowledge of foreign languages would be an advantage

Salaries, which will be dependent on qualifications, are extremely attractive and conditions of service are above average There are certain fringe benefits

Please write giving an abridged curriculum vitae to

General Manager,
Derwent Publications Ltd

Keep Your Powder Clean

THE Russian and American disarmament negotiators pulled a considerable rabbit out of the hat when they returned to Geneva a week ago and made public the agreement of their two governments on a draft of a non-proliferation treaty. Only a few weeks earlier, when the proceedings broke up for the holidays, it seemed very much as if the negotiators had reached yet another obstacle on the road along which they have been trudging for the best part of two years. The new and more specific form of the treaty upon which the Soviet Union and the United States are apparently agreed is designed specifically to meet the now familiar argument, put forward last year by the delegation from West Germany, that any non-proliferation treaty should allow the safeguards organization of Euratom to be responsible in Western Europe for the supervision of the safeguards procedures necessary to ensure that non-nuclear powers do not divert fissionable material to military ends. The German argument, supported by the Italian delegation, stems partly from the view that any other arrangement would be at once a slur on Euratom and an opportunity for industrial espionage. The objection to this view, held most vigorously by the Soviet Union but supported by a good deal of logic, is that it would be improper to allow membership of a private club such as Euratom to exempt a nation from the rules and regulations of an international treaty.

The new draft of the treaty which has appeared at Geneva is not so much a solution of this problem as a means of postponing it. Instead of spelling out the way in which a non-proliferation treaty would be policed, the new draft merely requires that signatories should accept some form of control and inspection which must be negotiated with the International Atomic Energy Agency beginning within six months of ratification. It is understood that nations will be able to negotiate with Vienna individually or in groups. No doubt they will also be free to settle for whatever system of control the IAEA chooses to specify. On the face of things, this is a clever move. For one thing, it will demonstrate that the IAEA remains ultimately responsible for the approval and design of all systems of control. At the same time, the new form of words will presumably enable the Euratom safeguards organization to assume responsibility for safeguards in much of Western Europe. With luck, no doubt the members of Euratom (with the exception of France) will be anxious for assurances on this point before they are prepared to sign. They would, however, be well advised not to push their luck too far. It is still something of a surprise that the Soviet Union has been prepared to modify in any important way its earlier insistence that the IAEA should be the only organization trusted with inspection.

Elsewhere, it is probably only fair to recognize that the loosening of the inspection clause in the draft treaty will eventually imply a somewhat less rigorous system of inspection than was originally foreseen, which may be a good thing and not the opposite. For if the IAEA delegates control of fissionable material in Western Europe to the safeguards organization of Euratom, it will be exceedingly difficult for it simultaneously to impose on independent signatories a system of inspection operated by its own men. There is evidence enough already that nations like India are exceedingly sensitive about the way in which the proposed treaty would make permanent the class distinction which at present exists between the nuclear powers and the others. They are unlikely to accept arrangements which would create another distinction between two classes of non-nuclear powers—those in Euratom and the rest. In these circumstances, if and when the treaty is ever ratified, the IAEA is likely to find itself encouraging the formation of regional self-inspection systems elsewhere than in Western Europe, perhaps reserving for itself chiefly the right of verification. This is probably a sound development for its own sake, if only because it has never been easy to see how the integrity of the rapidly growing nuclear power industry could be effectively guaranteed in fine detail from Vienna. By playing its cards well in the months following the ratification of a non-proliferation treaty, however, the IAEA could easily establish for itself a commanding position in the supervision of nuclear reactors throughout the world without incurring the trouble, the expense and the risks of a system of inspection which is meant to be thoroughly comprehensive. In other words, a weaker system of inspection than was at first proposed should help not only to bring the non-proliferation treaty within reach but to make international inspection workable.

That said, there can unfortunately be no assurance that an agreed text will emerge in the months immediately ahead from the disarmament committee at Geneva. The representatives of the super-powers have been putting a cheerful face on things, but the conference has not yet begun to tackle what may prove to be the most serious problem of all—the unwillingness of entirely peaceable countries to sign away their freedom to follow a course of military development which has become, as it happens, entirely respectable among the most powerful nations. More practically, there are questions of whether nations such as India can look for some degree of protection against attack in return for agreement to forgo the manufacture of nuclear weapons

If the smaller powers push these arguments strongly in the weeks ahead, the non-proliferation treaty could be held up for another year or more It is also only sensible to acknowledge that the smaller powers would be entirely within their rights in asking that the treaty should show either greater respect for their right to make decisions on defence policy on their own behalf or, preferably, that it should include some restriction of the right of nuclear powers to keep on manufacturing fissionable material for military purposes The willingness of the United States and the United Kingdom to throw their civil nuclear plants open to inspection is a gesture but not a real concession on this point In the same way, the inclusion in the new draft treaty at Geneva of a general undertaking that signatories will press forward to the objective of general and complete disarmament (or GCD as it is known among the specialists) will be most often interpreted as a formality In these circumstances, even the more realistic draft treaty which has now been designed may prove too stiff a dose of segregation for many of the smaller nations The next few weeks should tell

In for a Penny, in for a Pound

THE European Molecular Biology Organization (EMBO) has made a serious claim on public attention and even sympathy in the years since its small beginning in the early sixties. From the start—which is conventionally taken to be a conference at Ravello in September 1963—it has been plain that there is a valuable job to do in moving people from one European laboratory to another. EMBO has done well to collect enough money to start the ball rolling (and the Volkswagen Foundation, which has provided most of the support, deserves not to be forgotten). It has been something of an object lesson for other informal societies seeking some means of influencing events to see how much, in the last resort, depends on good organization Because EMBO seemed, at the beginning, to be as much a cosy self-congratulatory club as a more conventional learned society, it is not surprising that it provoked scepticism and even resentment, one of the indirect benefits of the funds which have been made available for fellowships in the past few years is that EMBO has been given a chance to demonstrate that it is a thoroughly open-minded society That done, it is only natural that most European governments should now be willing to support on a continuing basis the scheme for a mixture of travelling fellowships of various kinds In spite of the devaluation of sterling, even the British Government seems cheerful about this prospect The chances are that an international agreement on continuing support will be signed and sealed in April

The laboratory on which EMBO has set its heart (see page 314) is altogether a different proposition This, at least, is what some governments have been tempted to suppose For one thing, a laboratory employing several hundred people is a much more permanent undertaking of the kind from which governments almost instinctively fight shy It has also inevitably been asked why the molecular biologists are so keen on having a laboratory when there is no ready-made excuse such as the need to operate an expensive piece of equipment in collaboration—the prime justification of CERN In this connexion, the sceptics are well within their rights to point out how easy it is for laboratories which are established in a vacuum to remain in a vacuum more or less indefinitely The world is littered with institutions like that But a more powerful reason why governments have frequently hung back from the creation of an EMBO laboratory has been the fear that the establishment of a new centre of excellence in molecular biology could only serve still further to deplete the scarce supply of molecular biologists in national universities This, of course, is an argument which carries weight only with countries which already have a significant stock of molecular biologists and are anxious to do everything they can to husband it, but even then the reactions of similar governments are not entirely predictable In Britain, for example, the feeling in the Medical Research Council that an EMBO laboratory would thin out still further the laboratories already crying out for experienced men and women has been one of the reasons why the British Government has been conspicuously cautious in its discussions of the laboratory In France, by contrast, there have been no such inhibitions, to tell from some of the things which Mr M Schumann, the Minister of Scientific Research, says, the EMBO laboratory comes next in importance only to the *force de frappe* and the *plan calcul*

What is the truth ? And how should European governments react to the proposals now being made to them ? Perhaps the most obvious thing to say is that the documents which have been prepared in support of the case for the laboratory are an eloquent disproof of a good many of the doubts about the laboratory which have from time to time been raised The need for a concentration of resources is particularly well put For one thing, sheer propinquity is a blessing in a field in which the most skilful operators are often specialists in quite unrelated disciplines But it is also clear that molecular biologists are itching to undertake a number of large scale projects which share something of the monumental character of undertakings on high-energy physics Dr F Crick's "Project K" for making an exceedingly detailed study of the *K*12 strain of *Escherichia coli* is only one of many examples of how concentration may make it possible to tackle problems which have previously been inaccessible. Given this, and the fact that EMBO has at present such a high reputation that it would probably be able to attract the kinds of people necessary to ensure the success of an international laboratory, there is probably no need to fear that the project for an international laboratory would founder on intellectual grounds

The fear that an international laboratory would drain scarce talent from existing institutions is necessarily harder to deal with, if only because so much is bound to depend on estimates of how studies in molecular biology are likely to be stimulated by the creation of an international laboratory. Professor V. Weisskopf (page 317) is able to claim that the growth of CERN has not been accompanied by a decline of high-energy physics elsewhere in Europe, and what he has to say is powerful reinforcement for the case in favour of the European laboratory. At the same time, however, it is only possible to guess at what would have happened to high-energy physics in Europe if CERN had not been built. Most probably, the thirteen member nations would have been egged on by competition to spend more, in aggregate, on this branch of physics, but would not have had such good value for money. And in this spirit, of course, the possibility that a European laboratory for molecular biology may drain away people from national laboratories—unrealistic though it may be—is almost irrelevant. What matters is that the people concerned should remain in circulation as innovators and as teachers. If that could be assured, the EMBO laboratory would be at worst a more economical way of doing business than the present system in which funds for the support of research in molecular biology are dispersed throughout the universities of Europe. In reality, there is probably a good deal in the claim of the EMBO council that a European laboratory would be a means by which contributing governments could gain markedly from quite small extra investments. In the long run, it would even be reasonable for them to expect that a successful EMBO laboratory would restrain the strictly national demand for an expanding budget.

All this, however, is hair-splitting of a kind. The truth is that the sums of money necessary for the funding of the EMBO laboratory, large though they may seem in comparison with the scale on which biological laboratories are habitually financed, are an exceedingly small part of what Europe as a whole chooses to spend on research of all kinds. Even if the EMBO venture should turn out to be a sheer waste of money—and all the evidence runs the other way—no great damage would have been done. In the circumstances it will be a great misfortune if the governments whose representatives are now trudging back from Geneva make too much of the issues of principle involved, and neglect the wider opportunities which the EMBO proposals offer. And these, in the long run, are plain enough. Sooner or later it will be necessary to organize a great deal of European science on a co-operative basis. The sooner it is possible to set about the building of common institutions, the sooner Europeans will begin to profit from their common geography.

In that sense, EMBO and its laboratory are splendid opportunities for experiment.

No Academic Spending Spree

THE University Grants Committee has now published details of the allocations of recurrent grants to universities in Great Britain over the next five years. The figures, which were sent to universities at the end of last year, are published in the UGC Annual Survey for the academic year 1966–67 (HMSO, 3*s*. 3*d*.), together with the memorandum which the UGC sent the universities to explain "the strategic attitude" which the UGC has had to adopt in order to make a division of the resources. Sir John Wolfenden is cheerful about the reception the memorandum received from the universities—at least, he said in presenting the report, there had been "no major explosion from the universities" so far. The grants themselves confirm that the growth of universities is likely to move more slowly in the next five years than it has done in the last five. "Plain living and high thinking" was Sir John's recipe for the next quinquennium.

RECURRENT GRANTS FOR BRITISH UNIVERSITIES

	£ (million)
1967–68	150·79
1968–69	152·85
1969–70	158·57
1970–71	164·82
1971–72	171·10

(From 1968–69 onwards, the figures make no provision for equipment for teaching and research, which will be dealt with by separate grants.)

The memorandum lays emphasis on the need to expand undergraduate numbers, in particular in the arts and social sciences. Sir John defends this decision by pointing out that, in 1964, the actual numbers of science students in the first-year sixth forms of British schools declined. Despite this, the UGC has provided for a slight increase in the numbers of science students at universities. But social science and the arts, where the pressure on university places is greatest, must be allowed to expand the fastest. The UGC has not fixed limits on the number of postgraduates which universities can provide for, but the grants awarded do make certain assumptions about the proportion of undergraduates to postgraduates. As the report puts it, "It is, of course, open to any university to admit more than the number of students indicated in its separate allocation letter, if by internal economies, increased 'productivity' or any other means it thinks it can rightly do so".

The UGC has set in train a survey of the reasons why students entering universities fail to finish the course —the "drop-out" or wastage rate. At present in Britain, the wastage rate is running at about 14 per cent, but there is considerable variation both between departments and between universities. Suspicion has sometimes been voiced that some universities admit more students than they can possibly handle, and use the first year to weed them out. The survey, Sir John said, would try to sort out whether there was any truth in suggestions of this sort, and would try to make some estimate of the reasons for wastage. Vice-chancellors, he added, tended to be difficult about publishing this kind of information, so that discussion would be needed before it was finally decided what form the published survey should take.

In making the allocations to universities, the principal criterion is the number of students in any university. This year, for the first time, the UGC has also taken into account unit costs, and staff : student ratios. Veterinary students come out as the most expensive, with a unit cost of £1,136, and social scientists are the cheapest at £255. The staff : student ratio is most favourable in veterinary science, at 1 : 4·6, and least favourable in education, at 1 : 12·5. Physical science, the report says, has a unit cost of £376 and staff : student ratio of 1 : 11·3, but biological sciences are more expensive, with unit costs of £518 and staff : student ratios of 1 : 8·7.

Superannuated Dons

An alternative arrangement to the Federated Superannuation System for Universities receives consideration in a recent working party report, published by the Department of Education and Science. Headed by Sir George Maddex, the party represented a number of associations and committees and the government departments concerned. The alternative scheme which the committee considered is the terminal salary scheme.

The existing FSSU system is based on policies of assurance so that benefits reflect the actual amounts received as salary during an individual's career. This has led, the report maintains, to inadequate pensions. According to the alternative arrangement, a scheme would be adopted under which pension benefits would be directly related to the teacher's salary at retirement, thus giving weight to economic conditions at that particular time. The rates of benefit would be guaranteed, but the contributions would be fixed on a provisional basis. Because of a variety of reservations from members, however, the working party has been unable to make a clear recommendation in favour of either system.

The report includes an examination of the basic differences between terminal salary and insurance policy schemes, and it also considers the implications of tax and the National Insurance graduated pension scheme; the report compares them by working out the benefits in a number of typical cases. On a salary of £2,000 a year, for example, assuming a contribution of 5 per cent, the net charge borne by a teacher according to the terminal salary scheme would be £67 18*s*. 4*d*., whereas according to the existing scheme it would be £83 10*s*. 0*d*. The saving in net outlay in this case is 0·75 per cent of salary.

Figures of future FSSU benefits which are expressed as a percentage of benefits under a terminal salary scheme show that most teachers entering university service for the first time would do better with FSSU; the figures are, however, based on assumptions, certain of which, the report maintains, are of questionable validity. The working party agreed, however, that, if an alternative to the present system is required, the terminal salary scheme is the best that is possible in existing conditions.

Marriage of Convenience

The announcement that the British Motor Corporation and Leyland Motors are to merge provides Britain with a motor company of international size. It is also a company with several built-in handicaps, the most serious of which may turn out to be the way in which its factories are scattered about the countryside. Although this alone is likely to be a limitation on the amount of rationalization that is possible, Sir Donald Stokes, by common agreement the dominant force in the new company, will have plenty of room left for manoeuvre. His principal limitation in the short term is likely to be a shortage of funds, and the £25 million dowry with which the Industrial Reorganization Corporation blessed the union will come in very useful indeed.

Sir George Harriman (left) and Sir Donald Stokes.

For this reason, it is fortunate that the early decisions Sir Donald, and his Chairman Sir George Harriman, will have to make will involve saving rather than spending money. It is almost certain that BMC's extensive range of cars will be reduced quite rapidly, by the disappearance of the Daimler name and the phasing out of several other models, perhaps including the 1800. It has been said that the ranges of cars marketed by the two companies are complementary, but this is little more than the traditional incantation which is always murmured when two companies merge. In this case it is simply untrue—there is direct competition both in the sports car and saloon car ranges (the Austin 1300 and the Triumph 1300, for example) and since BMC took over Daimler there is also some overlap in commercial vehicles and coaches. So there is little doubt that some models will have to go; others will have to be introduced to challenge Ford's dominance of the middle of the range. Considerable economies are possible in dealerships and in export organization, and the intervention of Leyland makes it seem more likely that BMC will at last take advantage of the economies of scale which have been within its grasp since the formation of the Nuffield organization in 1952.

In research, neither company has anything to match the £1 million research laboratory which Ford has built. In Leyland, research continues to be done by the individual companies, with Leyland itself perhaps doing the lion's share. It has, for example, built a gas turbine truck, and has pooled its knowledge with Rover, which has also done a good deal of work on gas turbine propulsion. The twin problems of pollution

How BLMH Compares (1966 Production)

	Cars	Commercial Vehicles
General Motors	5,557,000	934,000
Ford	3,380,000	765,000
Chrysler	2,118,000	211,000
Volkswagen	1,219,000	84,000
Fiat	1,148,000	66,000
BMC+Leyland	788,000	173,000

and safety have also added to the amount of research necessary, but so far the idea of a central research laboratory for the group is no more than talk. The situation in BMH is very similar, although its body-making subsidiary, Pressed Steel Fisher, did open a central laboratory some months ago. Like most engineering companies, the motor companies have been slow to catch on to the benefits of large scale research. This is not to say that no research work is done, but rather that it is done in a diffuse way, and probably on too small a scale for such an important industry. In the short term there is little chance that this can be avoided—the immediate need for the new company is for some substantial profits.

No Naked Socialists

The Industrial Expansion Bill, heralded by cries of horror from the Confederation of British Industry, was made public last week (HMSO, 2*s*.). And despite the advance publicity—Mr John Davies, Chairman of the CBI, called the bill "mischievous and absolutely childish"—it seems unlikely to allow the Government a very strong hand in private industry. The bill provides in the first place for £100 million to be made available to help private industry in schemes which would benefit the national economy but would not be undertaken without support—the sort of support the Government has already made available to the computer companies, the aircraft companies, and more recently the aluminium smelters. The total amount available could be increased to £150 million if Parliament approved. The effect of the measure will be to allow support of this sort to be given without lengthy legislation, but in each case an industrial investment scheme will be drawn up, approved by the Treasury and finally approved by the House of Commons. The measure is hardly naked socialism, nor is it a licence for what is sometimes called "back-door nationalization".

There will, for one thing, be no power of compulsion vested in the bill, for only plans agreed between the Government and the company involved will be supported. The various ministries involved in the investment schemes will be advised by a committee to be set up by the Minister of Technology, and the bill also empowers the National Research Development Corporation and the Industrial Reorganization Corporation to assist the committee and provide advice of their own. The ministers involved will have to report annually to Parliament on the workings of the scheme.

There is no doubt that the bill enables the Government a measure of discrimination—some companies will undoubtedly be supported while others will have to do without. But this is hardly more than the Government already does through its purchasing function. In the absence of a large space or defence programme, it is argued, purchasing power alone is not enough to support the industries which need support. Hence the bill, which seeks to do in a more direct way what is achieved by space and defence programmes in the United States. Whether the attempt will be successful is uncertain—the intervention of government in private industry has not always been well judged—but even the CBI would hardly claim, for example, that Britain would now have a viable computer industry without Government support at crucial moments in the past.

The bill also provides for a number of measures which had already been announced. Among them is the loan to Cunard of £24 million to complete the Queen Elizabeth II, and the increase of the borrowing power of the NRDC to £50 million. The Shipbuilding Industry Board is to be provided with an additional £15 million, and £1 million is set aside for the purchase of the Beagle Aircraft Company.

Last Word on Torrey Canyon

Ten months after the incident, yet another report on the Torrey Canyon disaster has been prepared—this time by the committee of scientists convened by the Chief Scientific Adviser to the British Government, Sir Solly Zuckerman. Readers will be forgiven for asking whether they have heard it all before. Admittedly the information is clearly presented and very detailed, but there will be many who wonder why it has taken the committee so long to report.

The object is to collect the lessons learnt during the aftermath of the Torrey Canyon incident and to examine the measures to be taken in future, but this also has a familiar ring about it (see *Nature*, **216**, 533, 1967). As outlined in the report, the incident was tackled in six parts: how to deal with the oil remaining in the ship, how to dispose of oil on the sea, how to prevent oil reaching the coastline, how to treat beaches which might be contaminated, how to reduce dangers to marine life and how to co-ordinate the efforts of other bodies dealing with the threat to wild life.

The sequence of events and counter-measures is familiar enough, but it is interesting to note that methods for reducing pollution which were considered impractical in Great Britain were in fact used in France. For example, the French successfully sank oil with powdered chalk in the deep waters of the Bay of Biscay, where there seems to have been no damage to fisheries. Despite the heavy and continuous contamination of the coast of Brittany, detergent was not used and consequently there was far less damage to the flora and fauna.

What are the lessons learnt from the disaster? At the top of the committee's list is the fact that most of the decisions taken during the crisis had a scientific or technical basis. It suggests therefore that if there is ever another disaster on a similar scale, a team of scientists should again be appointed to co-ordinate scientific advice. Another recommendation is that every effort should be made to salvage a grounded vessel, and that the cargo should be removed by pumping wherever possible. Failing that, and if environmental conditions permit, the ship should be set on fire after opening the tanks, if necessary by bombing. The committee hopes that much of the research work which needs to be undertaken could be done on an international collaborative basis, perhaps co-ordinated through the Intergovernmental Maritime Consultative Organization.

Research is considered to be necessary into means of speedy transfer of the cargo from a stranded vessel and methods of firing oil in a stranded tanker and on the sea surface. The committee also recognizes the need to develop more effective but less toxic detergents and to investigate the effects of natural factors in the movement, dispersal and destruction of oil at sea, as well as of the factors determining the stability and formation of different types of oil–water emulsion. Other enquiries, it maintains, should be directed to the disposal of oil by sinking with high density material. The possibility of developing cheap, effective and floating oil-absorbent material and methods of collecting the oil-soaked material in open seas also needs to be examined. Gelling agents are at present expensive and cheaper ones need therefore to be developed. Furthermore, suitable coastal tankers equipped to spray detergent and to ensure that it is mixed with the oil are also desirable. Cheap and effective booms, primarily for protecting harbours and inlets, are not yet available but could prove useful if improved, while mechanical methods for removing oil from beaches and rocks could be reinforced by burning and steam cleaning—the latter having been used successfully in France. Finally, the committee maintains that further research is needed into the effect of oil and detergent on fish and other marine life, sea birds and coastal vegetation.

Too Much Steel

STEEL production capacity is considerably greater than the demand for it in OECD countries. This observation is made in the recently published OECD review of the iron and steel industries in member countries (*The Iron and Steel Industry in 1966 and Trends in 1967*, OECD, 21*s*).

Overcapacity in the steel industry has been a source of increasing concern since 1958 and in Europe in 1966 production of steel was 20 million tons below capacity. This imbalance between supply and demand has had destructive consequences. To maintain large production runs manufacturers have been forced to set export prices at low levels, which has in turn affected domestic prices in many countries. The downward pressure on prices has diminished profits and the ability to maintain a level of essential investment has been seriously impaired.

WORLD PRODUCTION OF STEEL, MILLION TONS

	1965	1966	Per cent change
ECSC	86·0	85·1	−1·0
UK	27·4	24·7	−10·0
OECD—Europe	127·2	124·3	−2·3
Canada	9·1	9·1	0·0
United States	119·3	121·7	+2·0
Japan	41·2	47·8	+16·1
OECD total	296·8	302·9	+2·0
USSR	91·0	96·9	+6·5
Other countries (excluding China)	56·1	60·1	+7·1
World (excluding China)	443·9	459·9	+3·6

World production of steel continued to increase in 1966 but in Europe showed a small decline. Japan is the only large producer whose iron and steel industry experienced a significant increase in production. In the first half of 1967 output in the OECD area continued at about the same rate as that recorded for 1966, the upward trend continued in Japan, but the decrease in the United Kingdom and Germany showed signs of levelling out.

Two basic trends discernible in the international trade in steel are, first, a levelling off or even a decrease in exports to developing countries, and, second, an increase in trade between industrialized countries. Developing countries not only lack the foreign exchange to import steel but in many cases are supporting indigenous industries. The increasing volume of trade between industrialized countries is caused partly by the need to make good shortfalls in production in the countries concerned, and partly by geographical factors, price differences and such competitive conditions as quality, delivery and after-sales service.

Investment expenditure in 1966 again reached high levels in Canada, the United States and Japan, but in Europe was lower than previous years. (In the United Kingdom, at least, the impending nationalization of the industry was probably one of the factors inhibiting investment.) Investment in Europe was usually devoted to modernization and short-term improvements in productivity. The report concludes on the melancholy note that the chronic overcapacity in the steel industry seems likely to continue for many years to come. International efforts to avoid or even alleviate the effects of overcapacity have been unsuccessful. Instead, individual countries have increasingly preferred to take steps to safeguard their own iron and steel industries.

Aluminium from Coal

THE British Government's plan to sell electricity cheaply to aluminium smelters in the hope of starting a new industry in Britain seems not to be going exactly as Mr Wilson intended. Alcan, an aluminium company based in Canada, has decided that it would prefer to buy its coal cheaply and build its own power station. The Government's intention was that the smelters should share the output of a large nuclear power station with the electricity boards, after paying a capital sum equivalent to the amount of electricity the smelter would need. Alcan has lent credence to the National Coal Board's claim that it is still possible to generate electricity more cheaply with coal than with nuclear power, and has at the same time given the electricity boards the uneasy feeling that Alcan is getting better terms than they are. Neither the coal board nor Alcan is revealing the price agreed for the coal, but it will be supplied in substantial amounts—1 million tons a year when the smelter is operating fully.

The Coal Board has also had discussions with another aluminium company, Alusuisse, which announced some weeks ago that it was interested in tendering for a smelter. So far these seem only to have been tentative, and no decision has been reached. But, from the point of view of the aluminium companies, there is much to be said for building a small power station sufficient only for their own needs. This spares them the need to satisfy the stringent demands of the generating boards, and makes the process of running the station very much easier. Moreover, for a small station, coal is likely to be competitive, while in the larger sizes the arguments in favour of expensive nuclear power stations are compelling.

The argument has been further complicated, perhaps deliberately, by the suggestion that Alcan might be willing to pay back to the British Government money it borrowed during the war to build aluminium plants in Canada. The sum involved is £50 million, and half was to be repayed in 1971, the other half in 1974. Repayment of this debt in dollars would be welcome for the beleaguered British economy. The Alcan plan would also be welcomed by the mining industry, which is eager to find new outlets for its products. The Coal Board says that most of the coal for the Invergordon smelter would come from the north-east coal field, and possibly some might come from Scotland.

So far the other aluminium companies which put in tenders for smelters—Rio Tinto Zinc and British Aluminium—are standing by their original intention to use nuclear stations. Meanwhile Alcan has other fish to fry—it is also to build a smelter in Japan, on the island of Hokkaido. The smelter, which will have a capacity of 130,000 tons (more than twice the size of the smelter proposed for Invergordon), is expected to come into full production in 1972. Production will start in 1970, and Alcan says that the Japanese market is expanding more quickly than any other. Although the 20 per cent annual expansion experienced between 1958 and 1967 is unlikely to be maintained, a more modest rate of expansion—perhaps 10 per cent a year—should still make Japan the second largest consumer of aluminium by 1972, after the United States.

Causes of Death

THE Area Mortality volume of the Registrar General's Decennial Supplement gives an analysis of deaths in England and Wales for the five years 1959–63. With the total number of deaths in the period being just over 2·7 million, the annual death rate per thousand of the population was just over 12·5 for males and just under 11·3 for females. Figures known as the Standardized Mortality Ratios (SMR), which are given to aid comparisons, express the actual number of deaths as a percentage of the "expected" number. Thus for the country as a whole the SMR is 100.

Deaths from all causes and from the sixteen most widespread diseases are first analysed into ten regions and conurbations, and then into the nature of the area, whether rural or urban of varying sizes. Then follow analyses for hospital regions, London and county boroughs and finally administrative counties, which are split into urban and rural areas. Seventeen diseases which cause fewer deaths are then listed and the figures analysed into three categories only for region, nature of area and hospital region. Separate tables are given for males and females and, as well as totals for each cause of death, the figures are split into six age groups—under 1 year, 1–4, 5–14, 15–44, 45–64 and 65 and over. A separate table gives infant death rates from seven different causes, as well as the number of stillbirths and the live birth rates for the various areas. For the five year period the total number of live births was just over 4 million, indicating an excess of births over deaths of about 1·3 million for the five years.

This supplement continues the series that has been produced by the Registrar General since 1851. It also continues to show that mortality was highest in the north-western region, as was found in the 1951 supplement. In general, rural districts had the lowest death rates, but density of population did not always produce high mortality. The SMRs for Greater London were below the national average for all causes, although those for lung cancer in the area were very high.

The large number of geological, economic and social factors involved in mortality figures complicate their interpretation. Official comment on the Area Mortality supplement is therefore to be published separately.

Patients in Hospital

THERE was an increase in the number of patients discharged from British hospitals in 1964, and a decrease in the average length of stay in hospital compared with 1962 and 1963. Men and boys stayed in hospital an average length of 18·3 days in 1964; women and girls (including maternity patients) averaged just under two days less (16·7 days). Between 1962 and 1964 there was also a drop in the number of beds occupied per million population. These are some of the findings in Part 1 of the *Report on Hospital In-Patient Enquiry* for the year 1964, which has just been published on behalf of the Ministry of Health and the General Register Office (HMSO, 31*s*.).

The report contains detailed tables prepared from the 1964 ten per cent sample of discharges and deaths recorded by National Health Service hospitals in England and Wales, except those for psychiatric, pre-convalescent and convalescent patients. The hospital in-patient enquiry has two purposes which are closely related—to provide administrative data for the hospital services in terms of diseases treated and of the characteristics of the patients who had these diseases, and to provide information which can be of help in assessing the amount, distribution and effect of illness in the community and in various sections of it. Hospitals collect all the information by completing forms for one patient in every ten on discharge or death.

The tables are a mine of information. They include analyses by sex, age, region of residence and diagnosis, and by source of admission (that is, whether from a waiting list, immediate or other type of admission) and diagnosis. Many of the tables are connected with length of stay in hospital, and from this the average number of beds used daily and in relation to the total population has been calculated. These figures are shown for diagnostic group, age, sex, marital status, region of residence and hospital department (speciality) and certain combinations of these factors. Significant conclusions could no doubt be drawn from these figures and those for 1962 and 1963. A discussion of the tables is in fact to be published later in a separate commentary volume covering the years 1962 to 1964.

An innovation in the tables is the singling out of the place where accidents happened to people admitted to hospital. Injuries, poisonings and the like are all analysed in great detail according to whether they were caused by road traffic accidents, accidents in the home, or "other" mishaps. Not surprisingly, head injuries (excluding skull fractures) account for the highest percentage (39·9 per cent) of the 102,830 victims of road traffic accidents who needed hospital treatment. Fractures of different parts of the body made up most of the rest of the total; burns, however, accounted for only 0·1 per cent of road traffic injuries. Poisons caused a high proportion of accidents in the home—33·1 per cent out of the estimated total of 133,490 home accidents noted in the enquiry. Figures are given for all kinds of poisons—even strychnine and belladonna are included in the results.

Agreement Signed

A TECHNOLOGICAL agreement between the United Kingdom and the USSR which has been talked of for some time was signed last week by the technology chiefs of the two countries (see *Nature*, **216**, 1060; 1967). The Russian delegation, which spent four days in London completing negotiations with the Ministry of Technology, was led by Academician V. A. Kirillin, Deputy Chairman of the Council of Ministers and Chairman of the State Committee of the Council of Ministers of the USSR for Science and Technology. Mr Anthony Wedgwood Benn, the minister, and Mr Fred Mulley, Minister of State at the Foreign Office, signed on behalf of the British Government. The agreement provides for investigation of topics of mutual interest to the two countries at all levels, and is seen as the beginning of a "special industrial relationship". Mr Wedgwood Benn hopes that each side will "discover what is interesting, and pursue it".

The ministers, or their deputies, will meet once a year to review the working of the agreement, with reference to the progress of scientific, technological and economic co-operation. Joint working parties will determine the fields for co-operation and will recommend specific subjects for investigation in the fields of research, development, technology and organization of industry. Contacts at all levels will be encouraged as a means of turning the agreement into action. Exchange visits for studies, training and consultation will be arranged. Facilities will be provided for research and practical experience in each country and scientific and technical information will be exchanged. It is expected that licensing arrangements will be made to suit circumstances as they arise. The agreement places no limit on the joint work that can be done, as it provides for "any form of co-operation in applied science and technology as may be mutually agreed".

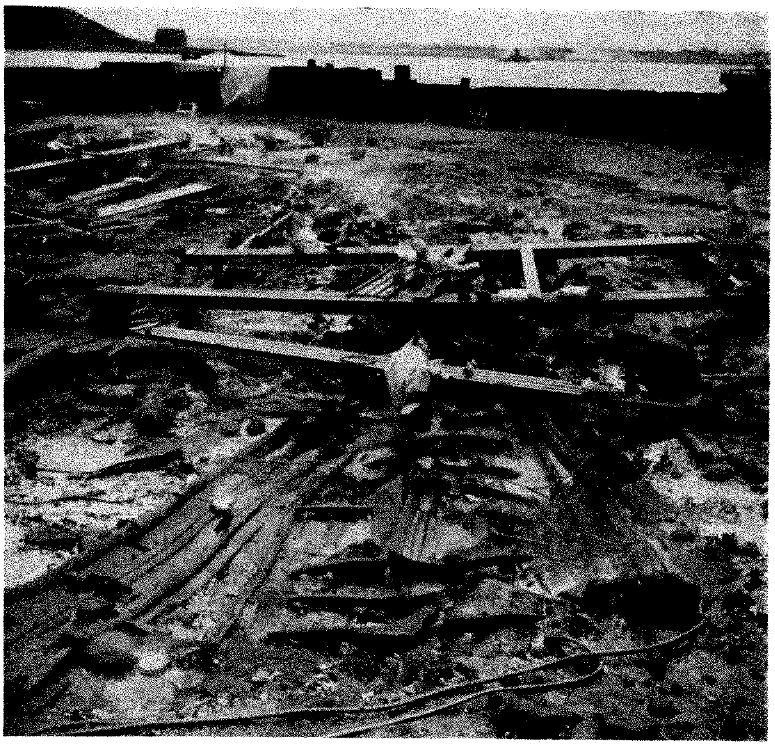
Five subjects which have been agreed, and are to be investigated by working groups, are educational technology, transport technology, materials research, information storage, processing and retrieval and non-conventional methods of food production. The ten items under the heading of industrial technology include the topics already being investigated by the Confederation of British Industry following the visit of a delegation to Russia last autumn.

Viking Ships on the Move

from Angela Croome

SIX years ago the Danish National Museum recovered the timbers of five 1,000-year-old Viking ships from Roskilde Fjord in an intensive and precisely calculated 3-month exercise which followed several years of underwater investigation. The ships, dated by carbon-14 measurements of caulking material, were known to be expendable hulks stripped down to essentials and sunk with stones across the main navigation channel to block access to the rich settlement at the head of the fjord which later became the medieval Danish capital of Roskilde. The fjord was shallow, so that a low coffer-dam was enough to enable pumping out and salvage of the timbers (see picture).

By now the first ship has completed the long and tricky "pickling" process needed to preserve its fragile timbers in air, and the work of turning these back into a ship can begin. This will take place in a specially built ship museum on the banks of the Roskilde Fjord where the first ship to complete processing is to move this week. Museum staff expect reassembly of the first ship to be completed this year when the new museum will be opening to the public. After that, visitors can watch the other ships assembled one by one. The ship being moved to the museum this week is made up of 5,000 individual pieces of wood. These have taken from 6 months to 2 years to be "rehabilitated"—the water-filled gaps must be filled with ethyl-glycol so that the wood, saturated for a thousand years in water, will not shrink when exposed to air. A cycling process in solution tanks heated to 60° C has been employed and has taken longer than originally expected. It may yet be a year or so before the remaining ships are ready for



The skeleton of one of the five tenth-century Viking ships emerges from the mud of Roskilde Fjord. When this picture was taken, in August 1962, the work of clearing the ships of mud and stones was two-thirds complete. Garden sprinklers are in use to keep the exposed wood damp.

reassembly. Each timber must conform to the original tracing in horizontal shape and size before reconstruction can begin. The third dimension can be produced by heating but not the stretching of basic length and breadth.

Each of the five ships is different. The one being moved for reassembly this week is a 40-ft. ocean-going cargo vessel such as was used by Erik the Red and his successors for the early Norse voyages to Greenland and North America—"Vinland" as the sagas called it. This is a stout, decked sailing ship of pine on an oak frame with a heightened freeboard. Another is a classical "longship" such as chieftains used on coastal forays, 90 ft. long and built of oak. Another is the coastal assault craft which is well illustrated in the Bayeux tapestry of the Norman Conquest of England (the Normans were descended from the Norsemen). The best preserved of the Roskilde Viking ships is an oak ship thought to have been used for coastal freighting in the Baltic. And there is a smaller boat which remains something of a mystery—nothing similar has been found in the records. It may have been used for net-fishing. It has neither deck nor oar-holes and is built of pine which at that period was unknown in Denmark. This suggests that it may have originated in southern Norway.

Mr Ole Crumlin-Pedersen, the naval architect who has been responsible for the finds, plans to build a full-size replica of the Atlantic craft with identical materials and a set of Viking shipwright's tools, to see how she handles at sea. He has already done this for the assault craft shown on the Bayeux tapestry and found it quite easy to load and land horses from the foreshore as shown in the tapestry.

Pattern of Research

from Our Special Correspondent

The MRC Metabolic Reactions Research Unit in the Biochemistry Department at Imperial College, London, under Professor E. B. Chain, shows a common pattern of research, as a public visit on Tuesday of this week illustrated. The pattern has four components: a belief that biochemistry done on complete organs or tissues is likely to yield results nearer to the reality of living animals than can be got from enzyme preparations; exceptional resources for making and processing analyses and counts of radioactive tracers in a multiplicity of materials; the facilities for pilot-scale fermentation on which Professor Chain insisted from the start; and the personal dominance which he still exercises. The unit has a scientifically qualified staff of 15 including attached workers and the department some 20. Interesting and potentially promising use of congenital obesity in mice is being made by Dr C. Chlouverakis. His most recent experiment shows a difference in response to insulin between diaphragm muscle and adipose tissue in these mice, and also an age effect. Muscle does not respond to insulin; adipose tissue in five month old animals does. By the age of a year the second response has disappeared and at the same time the weight of the animals levels out. Recent medical evidence on maturity-onset diabetes and obesity suggests that Dr Chlouverakis's research may be relevant to man. He plans next to look for biochemical differences associated with the tissue and age effects. Mr K. R. L. Mansford and others are working on the metabolism of complete hearts. They are interested in the partial revival of activity which follows the initial severe drop induced by oxygen deficiency. Dr H. F. Bradford, Mr K. Corbett and Dr S. P. R. Rose have gone some way towards establishing that the brain of the snail, which has cells at least ten times larger than the human brain, can be used as a simplified model from which a biochemical picture of the working of brains, including the interrelation of neurones and glia, may be in time built up. Other research, at an early stage, follows the demonstration by Dr P. Mantle in the department that agroclavin (closely related to the ergot alkaloids and in particular to LSD) has a central and specific inhibitory effect on lactation. Because agroclavin is much less toxic than LSD, study of the mechanisms by which it produces central effects, some of which appear to be shared by LSD, may give some helpful leads on the latter. This research should be worth doing in any case because of the side effects of agroclavin that may be brought to light. There is also supporting development work on automated instrumentation and data processing applied to biochemical methods of analysis and separation. Because of the opportunities that the unit and department together provide, there will be a case (in better times) for more senior posts in the department.

Applying to See Stars

The Science Research Council has set up a panel, chaired by the Astronomer Royal, to allocate time on the three large telescopes which it will eventually be supporting. These are the 74-inch reflector at Pretoria, leased from the Radcliffe Trustees for seven years from 1967, the 98-inch Isaac Newton telescope at Herstmonceux, now undergoing commissioning trials, and the projected Anglo-Australian 150-inch reflector at Siding Spring in New South Wales, half of the observing time on which will be available to United Kingdom astronomers. Observing time at the Radcliffe Observatory will be shared between the present staff, the Royal Greenwich and Cape Observatories and United Kingdom astronomers in general.

Astronomers based in the United Kingdom who wish to use the telescopes are asked to apply to the Secretary of the Panel, Dr A. Hunter, whose address is the Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, Sussex. The panel's duty is to consider applications on their scientific merits and to allocate time to individual users in accordance with SRC policy. Applications to use the Radcliffe reflector should be made one year in advance, and to use the Isaac Newton telescope six months in advance.

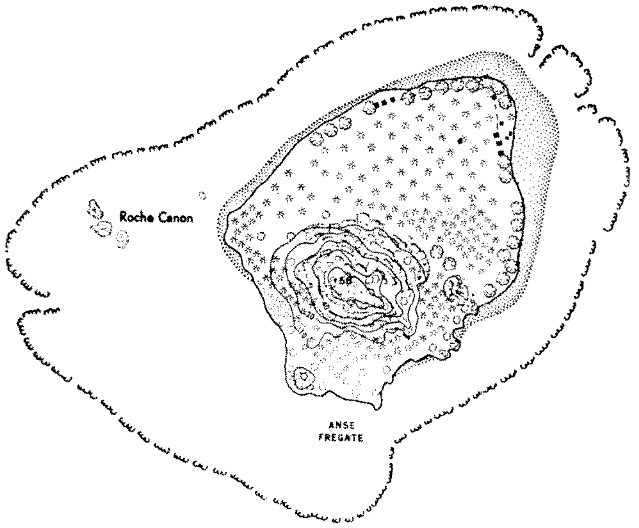
The panel itself disposes only of time, not of money; applications for grant support should therefore be made in parallel to the Science Research Council.

Cousin, not Cousine

Cousin Island is a small island of 67 acres (not to be confused with a neighbouring island, Cousine) in the Seychelles, about 800 miles north-east of Aldabra Island, which is shortly to be bought and turned into a nature reserve. That, at least, is the hope. For seven years the International Council for Bird Preservation has been bargaining to buy the island and now a firm offer for the island has been accepted. With the help of the British national appeal of the World Wildlife Fund, it is hoped that at least £50,000 will be raised to cover the purchase, to maintain the island as a nature reserve and set up a permanent research study centre.

The Seychelles are important because of the large numbers of endemic land birds they support; the fact that the Seychelles are an archipelago has probably had something to do with this. In the early eighteenth century, when the islands were first colonized, there were about a dozen endemic species on most of them. As the human settlements became larger and the islands more cultivated, the birds became rarer. Last century, at least three and possibly four of the species became extinct, and today the remaining endemic species are to be found on only one or two of the islands. The felling of trees and the introduction of rodents and cats by man are thought to have led to the disappearance and restriction in range of these birds.

Cousin Island is still fairly well stocked with endemics and from all accounts it would be ideal as a sanctuary and as a centre for studying the whole archipelago. Unfortunately, pigs are being allowed to run wild in the scrub of the north-eastern plateau with disastrous results for the bird population. It is becoming more urgent than ever, therefore, to buy the island for conservation, so that control can be kept over the vegetation and the introduced animals.



Cousin Island (Crown copyright).

It seems to be agreed that Cousin is particularly important because it is the only remaining home of the brush warbler (*Nesillas* (*Bebrornis*) *sechellanis*), of which only 50 are left. The bird breeds in dense cover, especially over the marshy area in the south-west of the island. The turtle dove, *Streptopelia picturata rostrata*, is also unique to Cousin. This endemic subspecies has been swamped in the other islands by interbreeding with an introduced form, *S.p. picturata*, from Madagascar. On Cousin, however, the endemic characters are retained to a great extent. The island is also one of the three remaining places where the Seychelles fody or toq toq (*Foudia sechellarum*) is found, and it also the only breeding place in the Indian Ocean of the rare lesser noddy (*Anous t. tenuirostris*), which otherwise breeds only on a small group off Western Australia. Apart from these rare birds, there are large colonies of the fairy tern (*Anous alba monte*), shearwaters and nesting tropicbirds (*Phaethon l. lepturus*).

There are also some giant tortoises introduced to the island by a previous owner. These are a different shape from those on Aldabra. Unfortunately the young were removed a long time ago as pets so that today only six adults remain. Apparently each tortoise has to be bought individually along with the island: it is anyone's guess how much each will fetch.

New Units for *Nature*

In accordance with the advice of the Royal Society Conference of Editors that scientific journals should adopt the SI system of units (*Nature*, **216**, 1272; 1967), *Nature* will be using the recommended symbols. This means that some of our abbreviations will be changed, as shown in the table. This will apply to all communications now accepted for publication.

Symbols previously used in *Nature*	Symbols to be adopted

In the article referred to above, giga was shown as 10^6 and not 10^9. One atmosphere should be $1{\cdot}01325$ N m^{-2}.

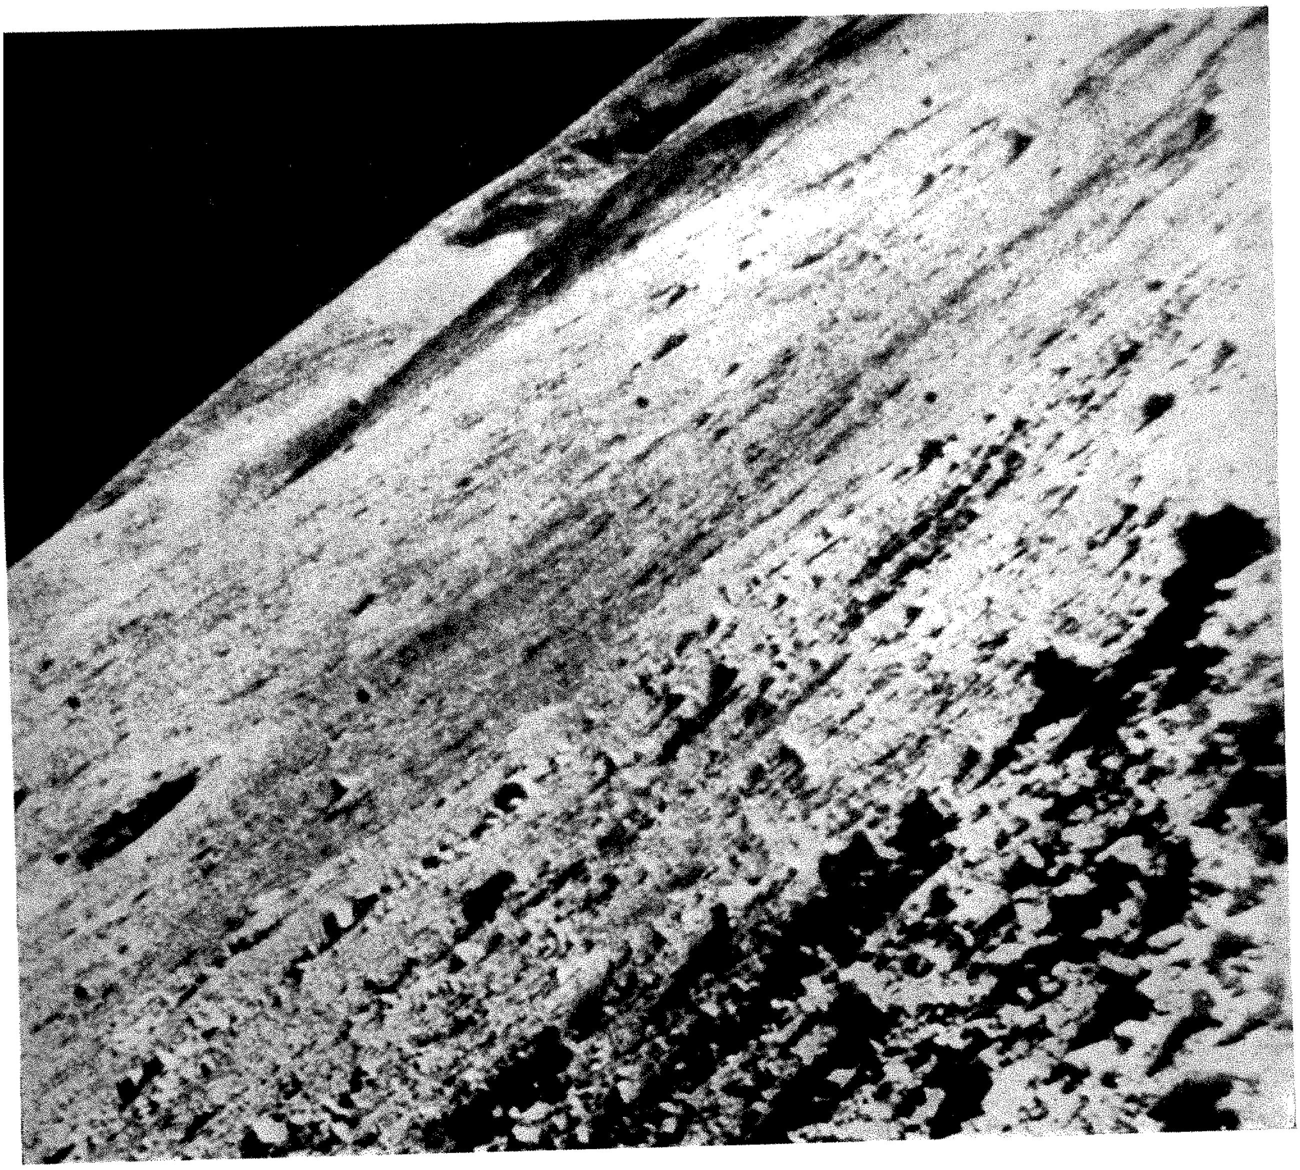
Parliament in Britain

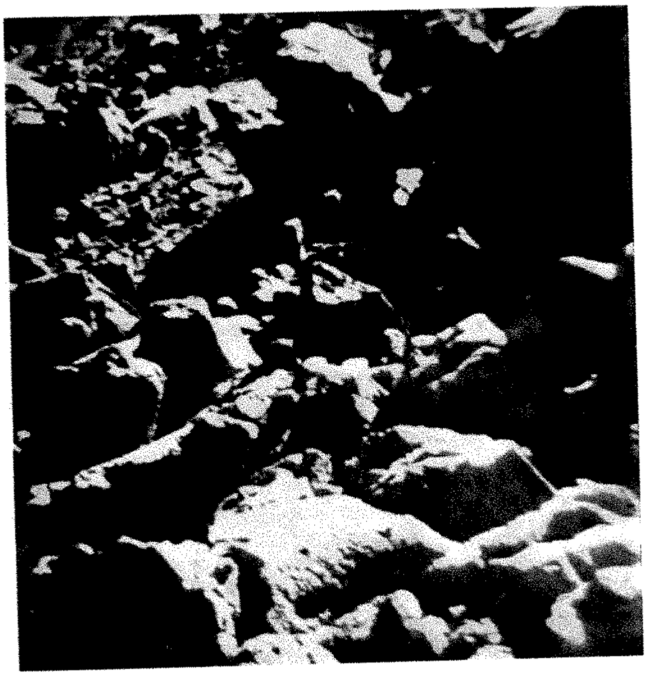
Forestry

Mr Hay, joint Parliamentary Secretary at the Ministry of Agriculture, Fisheries and Food, gave the acres planted by the Forestry Commission in England, Scotland and Wales in each of the ten years 1958–1967. In 1967, of the 52,500 acres planted, 11,200 were in England, 34,500 in Scotland and 6,800 in Wales. Now planting in Scotland was planned to increase to 50,000 acres a year by 1976. The planting programmes for England and Wales were under review. (Written answer, January 17.)

School Leavers

The Secretary of State for Education and Science, Mr P. Gordon Walker, stated that of school leavers in 1965–66, 5·5 per cent went into universities, 3·1 per cent to colleges of education, 1·1 per cent to full-time (and sandwich) degree and HND/HNC courses in further education establishments and 8·1 per cent to other full-time and sandwich courses at further education establishments, most of the latter courses being non-advanced. Between 50 and 55 per cent of boys and girls were expected to remain at school voluntarily in 1969–70 for a full year beyond the minimum statutory school-leaving age. (Written answer, January 17.)





More Moon Pictures

Pictures taken by the last of the United States Surveyor series of space flights have now been published. The spacecraft landed successfully 30 kilometres north of the crater Tycho, and the picture above shows a wide angle view of a cluster of rocks near the craft's landing site. The horizon to the north-east of the vehicle is formed by a ridge characteristic of the topography of the region, which is in the Lunar Highlands. The picture on the left shows rocky fragments in the highlands, and the centre of the picture is about 5 metres from the craft's television cameras.

NEWS AND VIEWS

No Smoking Licence

THERE may after all be some justification for the claim sometimes made by smokers that indulgence in this habit can provide a feeling of wellbeing and increase efficiency. On page 331 Drs Armitage, Hall and Morrison discuss the pharmacological basis for the tobacco smoking habit, and show that, in rats and cats at least, the nicotine in tobacco smoke can have these effects. Small injections of nicotine, in roughly the same dose as the amount taken in by a smoker smoking two cigarettes and inhaling deeply, made thirsty rats, trained to press a lever to obtain water, press the lever more frequently. The effects on the electroencephalogram showed that the activity of the cortex of the cat's brain was increased by a similar dose of nicotine. At the same time there was also an increase in the amount of acetylcholine produced by the cortex. These are both effects which characterize the normal physiological response of arousal; when animals, including people, rouse themselves from a state of decreasing consciousness, cortical activity increases and so does the output of acetylcholine from the brain. As Dr Armitage and his colleagues point out, it looks as though nicotine acts on the central nervous system, at least in small doses, by supplementing this normal arousal response and not by some effect peculiar to itself.

Larger doses of nicotine do not necessarily have the same effects and it would be tempting to connect the seemingly pleasant effects of small doses of nicotine with the finding reported by Professor A. H. Beckett (*Nature*, **216**, 587; 1967) that habitual smokers excrete less nicotine in their urine than non-smokers given the same dose of the drug; the smokers were metabolizing the nicotine to a greater extent than the non-smokers. It is of course impossible to say whether this has any connexion with the fact that it is small doses of nicotine which seem to give smokers their pleasure. There is no evidence that, like humans, cats or rats increase their capacity to metabolize nicotine after prolonged intake of the drug.

It would also be careless to say that these latest data indicate that smoking is at all a good thing. Nicotine is toxic in large doses; chronic poisoning, which usually arises from continued excessive smoking, can cause irritation of the respiratory tract, digestive and nutritional disturbances, narrowing of the blood vessels and increase in blood pressure. The carcinogenic effects of cigarette smoking are, of course, well documented by now. So, too, are the other ill effects of the habit of smoking cigarettes and even the other devices in common use for the production of tobacco smoke. The incidence of various heart ailments, for example, is known to be increased by smoking. Whatever the beneficial associations of nicotine, there is no question that it is best left alone. If that, however, is agreed, there may be great interest in what seems to be the rudiments of an explanation of why nicotine has such a hold on people.

Atomic Oxygen High Up

from our Upper Atmosphere Correspondent

MOST information on the neutral atmosphere of the Earth at heights above 150 km has been obtained from the analysis of the rate of change of the orbital period of satellites. This technique can only provide values of air density, however, and other atmospheric properties have to be inferred by fitting a theoretical model to the density data. Current atmospheric models are constructed by assuming a fixed composition at a height of 120 km, which is taken as the lower boundary, and then adjusting the temperature profile to make the model densities agree with observational values. The densities derived from satellite drag analysis can be reproduced by a wide range of boundary conditions and temperature profiles; it is for this reason that reliable composition measurements are required at heights near 120 km and that a recent review of mass spectrometer measurements of atomic oxygen in the upper atmosphere by von Zahn (*J. Geophys. Res.*, **72**, 5933; 1967) is of interest.

In current models of the upper atmosphere, the ratio of atomic to molecular oxygen at the lower boundary is assumed to be close to unity, which is near the mean of all mass spectrometer measurements. Von Zahn argues that measured argon concentrations imply a turbopause height of about 105 km and an eddy diffusion coefficient of 1×10^6 cm^2/sec; these values suggest that the atomic to molecular oxygen ratio is about 4 at 120 km. The measurement of a non-reactive species such as argon is much simpler than the measurement of atomic oxygen and more likely to be correct. It has been known for some time (*J. Geophys. Res.*, **71**, 4121; 1967) that there is severe loss and not merely recombination of atomic oxygen in "closed" ion source gauges. The use of "open" ion sources reduces the effect, but does not eliminate it. An indication that atomic oxygen measurements are too low can be inferred from the appearance during flight of a mass 44 peak, which follows closely the mass 16 peak. On the basis of laboratory calibration, only a negligible mass 44 peak would be expected and von Zahn concludes that it is produced in flight by atomic oxygen and can possibly be identified as N_2O or CO_2.

The existence of loss processes seems well established and, until they are better understood, measurements of atomic oxygen by rocket-borne mass spectrometers should be regarded as a lower limit. Densities measured by instruments aboard the aeronomy satellite Explorer 17 have been found to be systematically lower than those derived from drag studies. Since the same loss processes can also affect pressure gauges, this latest information reinforces the arguments already put forward (*Smithsonian Astrophys Obs Spec Rpt.*, 217, 1966, *Phil Trans Roy Soc*, A**262**, 172, 1967) to explain this discrepancy in terms of errors in gauge calibration

Ends in Common

from our Cell Biology Correspondent

THE base sequence of the last eleven nucleotides at the 3′-OH termini of the RNA from the closely related bacteriophages *f*2 and *MS*2 is GpUpUpApCpCpApCp-CpCpA Weith and Gilham first reported this sequence for *f*2 RNA last October in the *Journal of the American Chemical Society* (**89** **21**, 5473, 1967), and deWachter and Fiers have now reported the same sequence for *MS*2 RNA (*J Mol Biol*, **30**, 507, 1967) The two groups worked independently, and used quite different methods DeWachter and Fiers used a fairly orthodox approach, whereas Weith and Gilham adapted the periodate oxidation and base catalysed β elimination technique of Neu and Heppel (1964), and used columns of amino-ethylcellulose to absorb the 3′ terminal fragment (Lee and Gilham, 1966)

The outstanding feature of these 3′ terminal sequences is the terminal triplet CpCpA It is well known that all transfer RNAs end with this triplet, and so does tobacco mosaic virus RNA (Steinschneider and Frankel-Conrat, 1966) The 3′ terminal triplet of ribosomal 5*S* RNA from *E coli*, however, is CpApU (Brownlee, Sanger and Barrell, *Nature*, **215**, 735, 1967) and according to Lee and Gilham (1966) the 3′ termini of the majority of the ribosomal RNA from wheat germ ribosomes are GpU, GpG, ApA or ApC It is hard to believe that it is merely a coincidence that all the *t*RNAs and three viral RNAs that act as messengers terminate in CpCpA, and if it is not a coincidence, then the CpCpA triplet must serve some function DeWachter and Fiers speculate about this

They suggest the CpCpA triplet may be a device to protect the phage RNA chains from degradation by exonucleases in the cell, perhaps in the cell the CpCpA triplet acts in the same way as it does in transfer RNA and receives an amino acyl group on its 3′ OH end But it is clear from the work of deWachter and Fiers and that of Sugiyama (1965) that the phage RNA extracted from intact particles does not have an amino acyl group attached If such a group exists, it must be cleaved from the RNA before it is encapsulated It would be of great interest to know whether the CpCpA triplet of *f*2 and *MS*2 RNA is subject to metabolic turnover as is the CpCpA of transfer RNA and whether or not *m*RNAs other than phage genomes terminate in CpCpA DeWachter and Fiers further suggest that, if the CpCpA is not involved in protection from enzyme degradation, it may be part of a signal to DNA-dependent RNA polymerase to stop transcription, in which case viral RNA could be an escaped *m*RNA which has evolved into a bacteriophage but retained this signal

The other outstanding feature of the terminal sequence is the absence of an ochre, amber or UGA chain terminating codon If, as genetic evidence suggests, UAA (ochre) is the normal chain terminating codon, it is perhaps surprising that this codon does not occur at all close to the 3′ terminus In *f*2 and *MS*2 the ochre codon must be at least eleven bases in from the 3′ terminus, and quite clearly the terminal sequence cannot be involved in polypeptide synthesis

Inherited Neurological Disease

from a Biochemistry Correspondent

BIOCHEMICAL pathways in bacteria have been established by the study of mutant organisms in which a particular enzyme is missing In the same way, it is often possible to learn much about normal human metabolism from investigations of human beings who lack some of the active enzymes present in the normal human One of these "inborn errors of metabolism" causes a neurological disease known as heredopathia atactica polyneuritiformis or Refsum's disease

In 1963, more than twenty years after Refsum first described this inherited condition, Klenk and Kahlke showed that the chief biochemical abnormality in these patients was the presence of comparatively large quantities of phytanic acid (3,7,11,15-tetramethylhexadecanoic acid) in the blood The phytanic acid accumulates as a result of the partial breakdown of phytols from vegetable substances in the diet A diet with no vegetables, fruit, butter or meat-fat reduced the serum phytanic acid in two patients who had both been ill for 18 years, but only after they had been on the restricted diet for six months (L Eldjarn, K Try, O Stokke, A W Munthe-Kaas, S Refsum, D Steinberg, J Avigan and C Mize, *Lancet*, i, 691, 1966) The neurological symptoms of one patient seemed to improve as the phytanic acid level fell, but the other patient was too psychotic for neurological changes to be assessed

Animal metabolism normally breaks down phytanic acid by first oxidizing the carboxyl group to form pristanic acid (2,6,10,14-tetramethylpentadecanoic acid) which is then broken down completely by the normal β-oxidative pathway for the degradation of fatty acids The initial oxidation is known as an α-oxidation, and the most recent observations on Refsum's disease suggest that the enzyme for this reaction is present in normal humans but is missing in patients with the disease Steinberg and his colleagues (*Science*, **156**, 1740, 1967) showed that there was practically no production of labelled carbon dioxide when uniformly labelled phytanic acid was given to two patients, while normal human volunteers readily produced labelled carbon dioxide from phytanic acid Tissue cultures of the patients' skin produced labelled carbon dioxide from pristanic acid as readily as tissue culture preparations from normal people, but did not oxidize phytanic acid to form labelled carbon dioxide The authors suggest that since α-oxidation of fatty acids has only been identified in nervous tissues in animals, deficiency of this enzyme may adversely affect nerve metabolism and the phytanic acid accumulation is a secondary effect which does not cause the symptoms

Because Karlsson, Norrby and Samuelsson (*Biochim Biophys Acta*, **144**, 162, 1967) have now described a rapid and reliable method of identification of phytanic acid in the serum triglycerides by thin-layer chromatography, this test should be given to the blood of all patients with neurological symptoms whose origin is in doubt If restrictions on the vegetable intake of these patients do not reduce their symptoms, this would suggest that α-oxidation must be of great importance in nervous tissue, and deserves further investigation

Staphylococcal Responses to Hormones

from our Microbiology Correspondent

An aspect of animal pathology which appears to deserve more intensive investigation is the effect of endocrine secretions on microbial pathogens It has been suggested that hormonal action may be important in the regulation of toxin and antigen production by staphylococci, and evidence exists that reactivation of latent infections can be affected by hormones How do microbial infections interfere with the normal functioning of the endocrine system? What effects, both primary and secondary, do such hormones have on the course of a microbial infection? Answers to some of these questions have been provided recently by Dr William Yotis, who has examined the *in vivo* and *in vitro* response of certain bacteria to synthetic progestins and oestrogens (*J Bact*, **94**, 1353, 1967) The progestational contraceptive norethindrone was studied most fully in this context, but with the ever increasing use of this form of contraception the results are of wider relevance

The growth of *Staphylococcus aureus* was inhibited significantly *in vitro* when cultured anaerobically in the presence of 10–50 μg norethindrone per millilitre The hormone caused a protraction of the lag phase and reduced the maximum population obtained, these effects were severely lessened in the presence of oxygen In a developing furuncle, however, anaerobic conditions will arise rapidly and the maximal bacteriostatic effect of norethindrone, therefore, might be anticipated *in vivo* The synthetic oestrogen mestranol exerted an insignificant effect on the staphylococci, but its combined action with norethindrone was synergistic Although this potentiated activity was not realized with other androgens and oestrogens such as testosterone 17α-oestradiol and 17β-oestradiol, progesterone showed an additive bacteriostatic effect in the presence of norethindrone In contrast to its effect on Gram positive cocci, norethindrone did not inhibit the growth of the Gram negative enterobacteria screened This selective action may be due to differential permeability phenomena, or to transformation of the hormone Bacteria are well known to transform steroids, and the inability of norethindrone to inhibit staphylococci after about 8 h of incubation may be related to such a detoxication mechanism

The *in vivo* activity of norethindrone was tested by intradermal challenge of adult female rabbits with *S aureus* Prior treatment of the rabbits with the progestin produced a marked retardation of lesion development, but once a staphylococcal infection had become established norethindrone was without therapeutic action The prophylactic action, on the other hand, was effective for as long as 6 weeks after infection Precise definition of the bacteriostatic effect of norethindrone and other hormones *in vivo* cannot yet be made, but certainly a complex interaction of factors is involved Considerable evidence now exists linking the suppression of sebaceous gland activity by hormone administration with an improvement in acne vulgaris, while stimulation of connective tissue development is another likely factor in limiting or suppressing furunculosis Further analyses of the norethindrone effect could be important to our understanding of the course of bacterial infections in animals while also providing a useful system for assessing the microbiological properties of oral contraceptives

Classifying Algae

from a Correspondent

An International Symposium, "Algae, Man and the Environment", sponsored by Syracuse University and the New York State Science and Technology Foundation, was held at the Sagamore Conference Center and main campus of Syracuse University, New York, in June last year An international group of biologists who study freshwater algae and engineers who study waste disposal and pollution were able to discuss each other's research and to consider the problems of controlling the growth of algae in a variety of situations

One of the informal discussions was devoted to the classification of blue-green algae and the designation and preservation of algal cultures A meeting under Dr R A Opperman decided that though, like bacteria, blue-green algae are prokaryotic, their classification should continue to conform to the International Rules of Botanical Nomenclature This means that names should be accompanied by formal descriptions, with good illustrations of normal form and range, and that reference material should be preserved in herbaria As additional information becomes available about biochemistry, physiology, fine structure, virus susceptibility or the composition of the DNA, this should be incorporated into the description, and used to improve the classification

The problem of borderline organisms, more or less intermediate between blue-green algae and ordinary bacteria, is unresolved, and further detailed study is needed For practical reasons it seems simplest and best (at least for the present) to consider those organisms which most closely resemble blue-green algae in form—if not in pigmentation—as apochlorotic algae, and to consider flexibacteria, along with myxobacteria and the like, as organisms whose classification should conform to the International Code of Nomenclature of Bacteria

Cultures of algae provide valuable information about the potential range of form which clones may exhibit, and physiological, biochemical and cytological characteristics are best obtained from unialgal or axenic cultures It was therefore decided that critical experiments should be carried out on designated clones The date and source of isolation of strains or clones, accompanied by illustrations, should be included in the first full length publications which report their use

Numerical designation of strains and clones has hitherto been unsystematic and confusing The meeting suggested a unified system which would necessitate a single world register of algal cultures, and is to prepare formal proposals for publication and, it is hoped, adoption at a forthcoming congress

Many clones of algae are maintained by serial transfer in public and private culture collections, where spontaneous mutations may arise and accumulate as sources of variation Cells which have been frozen and maintained at the temperature of liquid nitrogen are now believed to be stable, more or less indefinitely, so that viable cultures preserved in this way are preferable in the interests of reproducibility The meeting recommended that reliable methods for the cryogenic preservation of algae be developed and adopted as soon as they are available

New Ways in the Infrared

from our Molecular Biology Correspondent

THE study of protein conformations in solution has in recent years become harder Except perhaps for proteins containing a high proportion of α-helix, interpretation of optical rotatory dispersion and circular dichroism has become increasingly complicated, chiefly because of the discovery that various side chains can contribute sizable Cotton effects of their own This uncertainty has made the development of other methods of observing polypeptide chain conformation and its changes increasingly desirable The recent resurgence of infrared spectroscopy of aqueous solutions is therefore to be welcomed and, as will be seen, it has already produced some promising results

The new work is by Susi, Timasheff and Stevens (*J Biol Chem* , **242**, 5460, 1967), who have looked at the infrared spectra, primarily in D_2O solution, of several synthetic polypeptides and proteins It is already well known that the so-called amide I frequency of the polypeptide chain is conformation-sensitive, and that the formation of a pleated-sheet (β) structure causes a considerable shift to lower frequency A less familiar observation, which was recently reported by the same group of workers, is the distinct, though smaller, shift which occurs when the chain enters the α-helical conformation Thus, it is shown that poly-L-lysine in D_2O solution can exhibit an amide I band at 1,635, 1,645 or 1,611 cm^{-1}, depending on whether it is in the random, the α-helical, or the antiparallel pleated-sheet state In the latter form there is also a characteristic weak component, due to another vibrational mode, at 1,680 cm^{-1} (In H_2O solution there are corresponding, though displaced, frequencies, but experimental difficulties generated by the high absorption of the solvent in this range are prohibitive) These band positions may vary somewhat from molecule to molecule, and will depend, for example, on the strength of hydrogen bonding In proteins then a certain spread of frequencies is found for each conformation, but this does not appear to be sufficient to cause any serious ambiguity

In a second article Timasheff *et al* (*J Biol Chem* , **242**, 5467, 1967) survey a large number of proteins In the majority of cases the peak of the amide I band lies either at about 1,650 or near 1,637 cm^{-1} The first of these groups comprises those proteins known to have a substantial proportion of α-helical structure—as myoglobin and lysozyme, for example The second consists of proteins known or thought to contain little α-helical, or other regular, structure In almost all cases, however, prominent shoulders are observed which reveal the amide I band to be complex Thus in lysozyme, the inflexion at 1,632 cm^{-1} must reflect the β-structure known to be present, and in many cases shoulders at 1,685 cm^{-1} also indicate the presence of antiparallel β-forms Indeed, in all cases for which crystallographic data are available, the conformation is qualitatively matched by the distribution of amide I frequencies In a few instances partial resolution of components of the band maximum is observed

Some striking effects engendered by denaturation are shown Insulin, for example, has been converted into three different denatured states in methanol solution, the position of the band-peak is unchanged, thus showing that the α-helical structure persists, in alkaline solution it shifts to a position characteristic of a random coil, and on heating at low *p*H antiparallel β-sheets appear These effects are paralleled by changes in the ultraviolet Cotton effects Again, β-lactoglobulin in the native state evidently contains a large proportion of β-structure, addition of methanol leads to denaturation with progressive formation of α-helix, though a different β-structure, associated with aggregation, also appears. Again the transition follows optical rotatory dispersion changes The utility of this approach is obvious it will assuredly find wider use

Algae on Film

by our own Correspondent

"MICRO-ALGAE—a Study of Movement and Multiplication" is the title of a film shown to the Linnean Society at a meeting on January 18 The film, which is intended primarily as a teaching aid, was made by Dr P E Brandham of the Royal Botanic Gardens, Kew

The film is silent, with explanatory captions, and in the twenty-five minutes for which it runs shows some very active fresh water algae Dr Brandham minimized vibration, usually a big problem in cine-microphotography, by standing the microscope on a rubber pad and a sprung base plate For the slower movers and for showing cell division, time lapse photography was used, with apparent accelerations of from 30 to 3,840 times

First, flagellar action is shown in a dinoflagellate, *Ceratium*, and in two euglenoid and three volvocacean genera Dark field microscopy shows the flagella particularly clearly, and in the water around *Volvox* small particles can be seen moving as a result of flagellar action *Phacus* is seen moving by its characteristic rolling motion, and looking like a sting ray doing contortions *Euglena* gives a perfect display of euglenoid movement

Time lapse photography makes it possible to see blue-green algae, including *Anabaena*, gliding around, and, among the Chlorophyta, the very slow movement which brings filaments of *Spirogyra* together for conjugation can be seen Diatoms are shown shunting to and fro—the ease with which they can change direction is clearly seen The desmid *Closterium acerosum* moves by a form of jet propulsion, by secreting mucilage from one end of its thin body, like toothpaste from a tube The mucilage hardens and *Closterium* is pushed forward There are also some fine time lapse pictures of cell division in several genera, including colonial algae and desmids

Crystalline Ribosomes

from our Cell Biology Correspondent

THE spatial organization of RNA and proteins in ribosomes will remain unknown until somebody manages to produce crystalline ribosomes which can be analysed by X-ray crystallography. Techniques other than crystallography, such as electron microscopy, dye binding and spectroscopy, can of course be made to yield limited information about the structure of ribosomes. Cotter, McPhie and Gratzer (*Nature*, **216**, 864, 1967), for example, recently proposed a plausible model of ribosome structure based on spectroscopic studies. Their data indicate that the outer surface of yeast ribosomes is predominantly RNA and from this they suggested what might be called a hedgehog model of ribosome structure, with the RNA looping out on to the surface of the particle and with the protein in the centre. But, because the experimental data are so limited, such models can never be more than sensible speculation.

What are the possible sources of crystalline ribosomes? The discovery in 1966 by Byers, working at Harvard University, that hypothermia *in vivo* induces the formation of crystalline sheets of ribosomes in chick embryo cells, caused great excitement because it raised the possibility that enough crystalline ribosomes could be isolated from these cells to allow crystallographic analysis. Alternatively these ribosomes might be crystallized *in vitro*. Unfortunately both these approaches have so far failed. The ribosome crystals which Byers has isolated from cells are too small for crystallographic work, and his attempts to produce large ribosome crystals *in vitro* have not yet been successful.

Crystalline ribosomes—in this case helices of ribosomes—also occur in the cysts of the amoebae *Entamoeba invadens*. Originally these helical structures were called chromatoid bodies, but since Barker's work in 1963 it has been suspected that they are crystalline ribosomes. In the current *Journal of Cell Biology* (**36**, 45, 1968), Morgan, Slayter and Weller report experiments which firmly establish this, but it is disappointing that they have failed to isolate intact ribosome crystals. Morgan *et al.* find that the ribosomes extracted from cysts of *Entamoeba* under various ionic conditions are dimers, monomers, or 50 *S* and 30 *S* sub-units, but never crystals. They calculate from the yield of monomer ribosomes that the chromatoid bodies must be dissociated into monomer ribosomes during the extraction. Ribosome crystals can only be extracted after fixation of the cysts, and after fixation of this sort the crystals cannot be dissociated into monomer ribosomes. The fixation must irreversibly cross link and denature the ribosomes. Thus although *Entamoeba* and chick embryonic cell ribosomes crystallize *in vivo*, neither material looks like providing a source of crystalline ribosomes for X-ray crystallography.

EMBO's Plan for a Laboratory

This week at Geneva there has been a meeting of the council of the European Molecular Biology Organization (EMBO) and representatives of several European governments to discuss the long-term support of EMBO's activities. The most controversial part of these proposals is that there should be a European laboratory for molecular biology; some countries—France, for example—have come out openly in favour of the laboratory, but others are known to be only lukewarm towards it. The following is an extract from the documents prepared by the EMBO council in support of the case for a laboratory.

MOLECULAR biology is a science rich with promise for the future, with applications to medicine, public health, agriculture and industry. Europe, in its own interests, should play its full part in the development of this field. The idea that we Europeans might rely on advances at a fundamental level made elsewhere and limit our own efforts to application of these is unrealistic and would be a false economy. Effective and competitive applications presuppose a wide base of fundamental knowledge and understanding. In this interdisciplinary field the development of local laboratories and centres in the individual countries is not enough. The establishment of a central laboratory in Europe, of a size and scope beyond the present human resources of any single country, would have an immense effect, not only because of its direct contributions to basic knowledge, but also because of its influence on the local laboratories. It would place European molecular biology in a unique position relative to any other country.

A central laboratory would provide a number of services to the European biological community at large, such as pioneering in the field of high powered instrumentation, the production on a large scale of rare materials such as enzymes and organelles, the maintenance of pure strains of experimental organisms and the sponsoring of special courses and conferences. In this respect, a single laboratory would in the long run be a source of economy by eliminating useless duplication (since it would avoid doing the same thing over and over in different places). Also in the balance it would be a source of far more trained biologists than it would absorb.

We propose a laboratory with an eventual staff of about 150 scientists and engineers (of whom about 20 would be of senior grade and have tenure), 60 visiting scientists, 40 postdoctoral fellows, and 310 technicians and other non-scientific staff. It is estimated that such a laboratory would cost between 8 and 9 million dollars a year to run.

The council's argument starts from the view that the promise of molecular biology is far from exhausted with the working out of the genetic code and the determination of the structures of four enzymes. On the contrary, "this approach to the study of living organisms is still in its infancy".

First of all, many of the apparently simple processes taking place in living cells are in fact of great complexity and are understood only in the barest outline, or not at all, at the molecular level. Thus we know the three-dimensional structure of a few protein molecules, for example, haemoglobin, but not how it expresses itself in the complex functioning of the molecule; we know in great detail the double-stranded structure of DNA, but still very little of the forces involved in the dynamics of its replication. The genetic code is indeed understood, as is the general scheme for its expression in the synthesis of proteins, but the actual mechanics of the assembly of the proteins being coded for is largely uncharted territory, taking place as it does through the intermediary of the ribosome, a cellular particle of very great complexity probably consisting of at least 20 different kinds of protein molecule as well as of nucleic acid molecules of unknown function; about the structure of this complex assembly, let alone its mode of functioning, we know virtually nothing. At present our knowledge of these processes is for the most part purely descriptive and phenomenological; it is easy to draw diagrams with molecules and intracellular particles represented formally by shapes like cottage loaves or twisted hairpins, and with processes shown as ingenious flowsheets full of arrows and feed-back loops, but it is quite another thing to relate these models to an actual physical process or a molecular structure.

When it comes to more complicated systems we are even more in the dark. As human beings our primary interest lies in the functioning of complex organisms like ourselves and the plants and animals on which we depend—that is to say, of organisms characterized by highly differentiated tissues and by the possession of sophisticated inter-cellular organization. Systems of this kind, although they transcend the cellular level of complexity, will demand for their understanding the same kind of thinking and the same experimental approach which has been so successful at the lower level. After all, living beings are all constructed of the same basic ingredients, and the same principles are at work in the behaviour of the most complex as those governing the functioning of the simplest.

As Europeans we believe that Europe, in its own interests, has a particular responsibility to take part in this activity on a regional basis. Many of the key discoveries which triggered these developments were made in European laboratories. Today, the initiative has to a substantial extent passed to America, where the very large resources available for scientific research have been liberally and wisely applied in this field. The intellectual capital of Europe is not being exploited to the full on home ground. EMBO has made a number of proposals to remedy this unsatisfactory situation, some of which (for fellowships, travel grants, summer courses, etc.) have already been implemented on a small scale, and a more extended programme for future activities of this kind has been accepted in principle by the European governments represented at the European Conference on Molecular Biology held in Geneva in April 1967. In our opinion the most important remaining part of our proposals, without which the rest will not come to full fruition, is the establishment of a European laboratory of molecular biology.

Why a Laboratory?

There are good reasons for establishing large laboratories in fundamental biology, both in the interests of good research and in the interests of good training in the methods of research. In this field everyone is a specialist in some particular area or technique; the real advances come from cross-fertilization among specialists, from understanding other people's ideas and techniques, and from day-to-day exchange of ideas—in short, from the interaction of differing attitudes and skills—and all of these are best achieved by propinquity. As to training in research, it may well be argued that at the predoctoral stage the scientist should often concentrate rather narrowly on acquiring a particular set of skills, but after the PhD, when he should be forming his own ideas and developing an independent research programme, the young post-doctoral fellow needs to be in a large laboratory where work is going on in many aspects of the field.

The argument for large institutes of fundamental biology is not the same as that in the case of high-energy physics, where the need (now satisfied by CERN) was for a very powerful and expensive machine which could only be provided in a central institute; in biology the essential "plant" is, rather, an interacting group of differing techniques and talents, each only moderately expensive by itself, but in sum costing so much as to be beyond most national resources, financial or—especially—human.

The EMBO laboratory which we propose on the basis of this philosophy will have the following features:

1. It will provide a centre for the vigorous prosecution of basic research of the very highest quality within the framework of an integrated programme.

2. The senior staff of the laboratory, all of the highest calibre, will consist of a small group of permanent full-time scientists, together with a number of others who agree as a matter of principle to spend a part of each year there over a period of at least several years. The bringing together, even for limited periods, of investigators from several countries will create a real European community of scientists, to the benefit of each individual country. It will make the EMBO laboratory the effective headquarters of a concerted research programme.

3. The laboratory will perform valuable functions in connexion with the recruitment, the training and the employment of scientists and technicians.

There is another role which the EMBO laboratory will play, less fundamental perhaps, but of great practical and indeed financial significance. Because of its size and resources, it will be in a unique position to offer to other laboratories a set of service facilities which at present are for the most part not available at all, or which, if they do exist, are dispersed over a large number of centres, with resulting loss of accessibility and efficiency.

The Scientific Programme

Though it is in the very nature of scientific progress that the precise directions cannot be forecast, we believe that there will be two main areas of attention; on the one hand the following up of what we know today at the simpler level of the macromolecule and the sub-cellular particle, and the extension of the analysis to the integration of the whole cell; on the other hand, a first application of molecular concepts to the problem of the relationship and co-ordination of cells in higher organisms—it goes without saying that this is a subject of far greater complexity and of extreme technical difficulty.

The concept of information lies at the very roots of any understanding of living organisms and indeed of human behaviour, and forms the core of the fundamental problems which we propose as the basis for the scientific programme of the laboratory. However, the whole complex of issues which arises greatly exceeds the capacity of any single institution and it is necessary to be selective. We accordingly propose for the present to limit the programme of the EMBO laboratory to five main assigned themes.

Structure of biological macromolecules. It is of prime importance to explain the functional behaviour of the giant molecules of biology, at present understood only at a phenomenological level, in terms of their three-dimensional structures. Why is it that in different haem proteins the haem behaves so differently depending on its environment? What is the nature of the conformational effects that explain the way in which activators and inhibitors exert their influence on an enzyme so that it may either be brought into play or prevented from going too far? As a result of recent developments in X-ray crystallography we now know for the first time the three-dimensional structure of several respiratory pigments and enzymes at a resolution of about 2 Ångstrom units, and there is every prospect that such knowledge will be extended to many other proteins, nucleic acids, and so on in the course of the next few years. Furthermore, recent dramatic improvements in methods of synthesis of proteins and nucleic acids make it almost certain that we can soon produce long sequences to order

The molecular basis of the immune response The capacity of an animal to develop an antibody in response to a foreign protein, possibly resulting from the presence of a pathogenic organism, obviously represents one of the most important evolutionary adaptations The picture of what is involved here is just beginning to emerge in its main outlines—the way in which certain serum globulins of characteristic size and shape, which have the property of combining specifically with the foreign molecule, are produced selectively Yet we have very little detailed understanding of what is involved, whether, for example, the antibodies are produced in some way *de novo* or whether all contingencies are provided for in the genetic make-up of the animal, and, if so, just what triggers the production of the antibody The antibody problem is in part a genetic one, in part a matter of the relation of structure to function and in part a question of cellular regulation The practical consequences for medicine and public health of a better understanding of this subject can hardly be overestimated

Viruses Closely related to the problem of the immune response, particularly in its implications for medicine and public health, is that of the nature and structure of the viruses Much is now known of the highly ordered structures of these particles, which stand at the dividing line between living and non-living matter, and of the organization of the nucleic acids and proteins of which they are largely composed It is now clear that the introduction of a virus particle into an organism is equivalent to the introduction of a piece of foreign genetic information which takes control and diverts the cells from their normal function The problems presented here are of the greatest interest in relation to control mechanisms both at a genetic and a metabolic level, and on the practical side lie at the heart of an understanding of many diseases Indeed, there is reason to think that a closer study of the viruses may provide a clue to the solution of the cancer problem

Some aspects of the functioning of the nervous system The problem of the genetic code is now essentially solved However, this is only the simplest and most basic of the problems involving information theory presented by the organism The corresponding problem at a more complex and even more challenging level is the storage, transfer, reassortment and retrieval of information in the nervous systems of multicellular organisms Is the basis of these phenomena, lying as they do at the root of adaptation, learning, response and indeed consciousness itself at all the same as that of the genetic code, and if not, what is its basis ? At present we cannot even hazard a reply to this outstanding question The answer will result from still unforeseen developments in a variety of subjects such as the study of membranes and of the control mechanisms which govern their structures, electrophysiology, and the chemistry of the gate mechanisms involved in the transmission of impulses across the synapse

Project K This theme takes its name from a particular strain, known as K12, of the bacterium *Escherichia coli* Today for the first time it is realistic to contemplate embarking on a programme directed towards a total understanding of the working of a single, characteristic unicellular organism—of its chemical make-up, of the many complex chemical processes taking place within it, of the mechanisms of its energy production, of the storage and expression of its genetic information, of the mechanics of its reproduction, and of its interaction with its environment Just because the genetic code is universal, because all kinds of cells use the same chemical pathways mediated by very similar catalysts (enzymes), it follows that this total understanding of one particular cell, even though it be a micro-organism, would throw a flood of light on the whole domain of cellular organization, including the economy and behaviour of a human cell The eventual rewards of such understanding would be the possibilities of practical control of cellular processes, with possible applications in medicine, in agriculture and in industry

Table 1 RELATIONSHIP BETWEEN THE FIVE THEMES AND THE FIFTEEN GROUPS

Working groups	Structure and function of proteins	Viruses	Chemical basis of the immune response	Nervous system	Project K
Protein chemistry	×	×	×		×

Neurophysiology				×	
Immunology	×		×		
Membranes	×			×	×
Computation	×	×	×	×	×
Production	×	×	×		×
Instrumentation	×				×
Animal and plant house	×	×	×	×	×

It should not be thought that these selected problems are fixed for all time, or even for more than a few years They have been chosen on the basis of the present state of biology, as well as their special suitability for attack at an international laboratory They will inevitably give place to others as the subject evolves For example, a problem not yet ripe for study at the molecular biological level is the mode of action of hormones, in a few years this might well find a place among the major objectives of the laboratory.

The council's document goes on to describe how the proposed laboratory would be organized into fifteen working groups of various sizes, and Table 1 shows how these would be linked with the five themes singled out for special treatment in the initial programme at the laboratory

On the staff and site, the council's document includes the following observations

The overriding consideration in the appointment of staff at every level should be ability "the laboratory would not succeed, and would not be worth establishing, unless its staff were of quite first class quality". Only a few senior scientists and engineers, for the most part group heads, would have tenure These would amount to something like 10 per cent of the total scientific population, say, 25 individuals in all The rest would be appointed for limited terms, but there would be possibilities of renewal so that an occasional young man might look forward to making a career in the laboratory.

In addition to regular staff, the laboratory would have a large number of visitors and trainees, who would represent an equally important part of the programme To a large extent these would probably receive support from sources outside the laboratory, including the EMBO Foundation

Among the factors governing the eventual choice of a site for the EMBO laboratory are the following

(1) Intellectual milieu The scientific work of the laboratory would greatly benefit from distinguished intellectual surroundings, both in the strictly scientific and the general cultural sense

(2) Other amenities—climate, housing, international schools, language, countryside Such factors would be important in attracting the senior visitors (and their families) whose presence in numbers would be essential

(3) Attitude of the host country A positive and continuing welcome and enthusiasm by the host country would greatly assist the establishment and subsequent development of the laboratory

(4) Accessibility A reasonably central position and good communications by air are important considerations in view of the constant coming and going of visitors from all parts of the world

(5) Local availability of services and materials The laboratory would benefit greatly from being situated in a place where skilled labour, servicing facilities and normal supplies were readily available locally

On the basis of its estimates of the scale on which the EMBO laboratory would operate, the council has been able to construct a budget for the construction and operation of the laboratory for the first decade or so of its existence (Table 2). It proposes that the head of the laboratory (as at CERN) should be a director-general, and the EMBO council emphasizes that this official should be appointed at the time work is authorized When operating at full strength, the laboratory would employ 122 *scientists as well as* 30 *"physicists and engineers", would have* 100 *or so visiting fellows on the premises and would need some* 300 *people as supporting staff*

Table 2 ESTIMATED BUILD-UP OF EXPENDITURE

Millions of dollars at 1967 prices Year 4 would be the first full operating year, and year 8 that in which the scale of operations reached a plateau

CERN and the Proposed European Biology Laboratory

In support of the case which the EMBO council has prepared, Professor V. Weisskopf, director-general at CERN between 1960 and 1965, has provided the following argument in favour of European laboratories.

IN connexion with the plans for an international biological laboratory in Europe, it might be useful to write down the experiences which we had in running CERN, the international high energy physics laboratory. I had the privilege of being the director-general during the time when the construction period of CERN was over and when the research activities were just about to start I therefore had an opportunity to see the effect of research at CERN on European university life at a most critical time

I remember that at the time of the founding of CERN, university circles in Europe were seriously worried about the effect of CERN on the staffing of their own national laboratories Naturally it was feared that such a well equipped and attractive research opportunity would attract the best and the most productive people away from the national laboratories, and as such deprive the national laboratories of their most important people, and by this means of their most important educational effect on students of the universities It was also feared that the centre of ideas and discussions would be removed from the universities to Geneva, so that the great European research centres would be relegated to a second order position

High Standing

When CERN was developed, these reasons were taken very seriously, but they were set aside by the absolute necessity of having an international laboratory of high energy physics because of the fact that no national institution was able to collect the funds necessary to build accelerators of the size which CERN was able to provide. Although the danger for the universities was realized and appraised, it was thought that there was no other way to bring Europe back into the first line of fundamental physics research—a position which it had indisputably held until the destruction of science in Middle Europe by the Hitler regime

It was one of the most exhilarating and encouraging facts of the development of CERN that this fear did not materialize In fact, it turned out that the existence of CERN has had a positive effect on university life, far beyond any measure which could have been predicted at the outset Let me try to sketch this surprising development

First of all, the construction period of CERN did not take many of the first-class research people away from European universities Clearly a construction of this size mainly involves people of engineering interests who did not play a great part in the process of education of physics itself However, a number of personalities who have been well known and important in physics education were taken away from a few universities, particularly in Switzerland, Germany, Italy and the Netherlands The number, however, was small enough not to make a decisive effect on the educational system of physics in these countries

Young Leadership

When CERN began its research activities, the situation had changed to some extent. It was, however, the conscious purpose of the CERN administration that leadership in that kind of modern research should be mainly in the hands of young people. This is why the additional research members who came to Geneva several years before the actual research—the people who were most active intellectually in the preparation of experiments—were only partly people who had previously taught in European universities (It is clear that research of this kind must be prepared several years before it begins, CERN made the mistake of neglecting this point to some extent and as a consequence productive research started later than might have been possible) To some extent they were people who had previously emigrated to America because of the much better facilities available and who had come back because of the promise of having similar facilities in Europe. The administration put special emphasis on giving these young people the greatest possible freedom of initiative I admit that this was not an easy task because it was against the general European tradition of leaving responsibility in the hands of older persons We therefore did not always succeed, but we tried in many cases to do our best

Slow Beginning

Research at CERN started quite successfully but, as indicated here, somewhat later than would have been possible This delay had the consequence that some of the fundamental discoveries which could have been made at CERN were actually made in the United States at the

Brookhaven National Laboratory However, a few important discoveries, made at CERN but characteristically with the small machine with which the European scientists had had more experience, had lifted morale and given those in the laboratory a sense of being in the forefront of research When, after two or three years of running, CERN had taken its place among the best and most productive institutions of its kind, research was carried out by a large number of groups An important part of the research was undertaken with bubble chamber pictures taken at CERN and evaluated at installations placed at different national universities

National Universities

The influence of this type of research on the national universities was quite remarkable Activity in high-energy physics increased all over Europe The European universities were no longer forced to beg for bubble chamber pictures from American institutions; they could get them directly from CERN The bubble chamber programme was always considered as a collective programme among the European countries, in which all institutions had a voice in deciding what pictures should be taken at CERN Many university people spent a certain time at CERN installing facilities and thus became acquainted with the details of the set-up, an important condition for successful evaluation work In other kinds of experiments, such as spark chamber and counter work experiments, the chief activity was at CERN, where the participation of the universities was, to begin with, relatively small

The increase of interest in high energy physics at all European universities produced a strong demand for new positions and professorships in this field in a surprisingly short time These positions were usually filled by young people who had worked for several years at CERN, either after some period of training in the United States or directly from their home countries For example, we have provided about six full professorships in Germany, two full professorships in the Netherlands and several others in different countries of Europe. More accurate statistics are available, it would be my estimate that at least fifteen positions around Europe were filled by young people who were trained at CERN Most of these people would have ended up in the United States were it not for CERN It should be mentioned that at least three senior physicists with the rank of full professor in the United States have since taken positions at CERN or in Europe

Supplying Professors

This 'invasion" of CERN professors into European universities had a very definite effect These professors did not stop their work at CERN when they joined their universities They spend their free time mainly at CERN and they have sent assistants, graduate students and other younger helpers to CERN in order to continue their lines of research or start new and promising investigations

The effect was that, by the end of my period, more than half of the experimental work at CERN was initiated or prepared by people who had been trained at CERN but who had received professorships at national universities Thus CERN has never been and is less than ever an institution independent of the university life of Europe It is an integral part of it, and it has not only supported but has clearly increased the activity and productivity of elementary particle physics in European universities It has successfully stopped and reversed the brain brain to the United States

Let me add that this effect is by no means restricted to the large and rich countries such as France, Germany or England Quite the contrary, those countries have their own opportunities to perform high energy experiments with their national institutions such as Saclay in France, in Rutherford Laboratory in England and DESY in Germany It is my conviction that the small countries have in fact taken advantage of CERN to a far larger degree—relative to the amount of money which they have put into the centre—than have the large countries Before CERN was active, it would have been almost unthinkable that countries like Norway or Austria could have maintained such a high degree of high energy physics for the amont of money which they actually pay to the CERN laboratory

The narrow collaboration between universities and CERN has had an enormously stimulating effect on the universities and has increased considerably the number of students interested in this fundamental field But it had also created certain administrative problems for the universities Professors had to be absent from the university much more frequently than usual, costs of travel have had to be met, a new way of life for laboratory personnel has had to be created Most universities were not too sympathetic to these innovations They reacted shortsightedly, not realizing that the alternative is no modern science and the loss of their best professors, students and technicians to the United States New solutions must be found, though not much has been done so far I suggested double professorships, where alternatingly one of the pair is at the university teaching and caring for the students and the other is at CERN working at the apparatus This solution has never been tried out in Europe, although it works quite well in my present department at MIT I do not pretend that there are no other solutions to this problem Archaeologists have worked for ages at places far removed from their universities

This report may give the impression of being too sanguine and optimistic I cannot help feeling that one of the most gratifying experiences as director of CERN was to see the stimulating and invigorating effect which that institute had on European physics In comparing CERN with the proposal of a biological laboratory we must beware that the element of building a very large accelerator does not exist To my knowledge, there is no instrument in biology which a single nation could not afford to provide for itself if it considered this was necessary

However, I have tried to show that the advantages of CERN go beyond the provision for European countries of a large accelerator A productive international intellectual centre has been created where young people have found a meeting place equipped with all modern facilities Here they were immersed in an atmosphere of active research, of the highest possible level Such a place is the best breeding spot for professors for national institutions, whose scientific level will by itself adjust to the level of the centre institution

United Europe

It is also important not to forget the importance of such centres for the idea of a united Europe The spirit of CERN and of a future biological institution is the spirit of a cultural European unity which exists but has had only all too few realizations

I would fervently hope that the Biological European Institute becomes a reality, but I also hope that it will be situated in the neighbourhood of CERN These institutions should become the nucleus of a European graduate school The arguments brought forward by these remarks should have amply proved that a European Graduate School of Science would never weaken national institutions It could only have an invigorating effect on each national university by raising the level of research, by providing a pool of potential candidates for jobs, and by reversing the brain drain It is Europe that has created modern science, it is high time that Europe becomes aware of the fact that it still could be the strongest supplier of scientific intellect

Glaciology and the International Hydrological Decade

by
J. W. GLENN
Department of Physics,
University of Birmingham

Snow and ice constitute an important part of the world's reserves of water. What follows is a description of some of the plans which have been made within the International Hydrological Decade for the study of these reserves.

THE great majority of the water on the surface of the Earth is in the form of salt water in the sea, but of the fresh water some 80 per cent is in the form of snow and ice, so that it is not surprising that a study of the snow and ice on the Earth should form an important part of the programme for the International Hydrological Decade. Of course, most of this snow and ice is in the great ice sheets of Greenland and Antarctica, about which much more knowledge has been gained from work started in the International Geophysical Year; in particular, measurements of the depths of ice in these ice sheets have provided some sort of an answer to the question of just how much water there is in this form. This problem is not perhaps of immediate practical importance, but in many parts of the world where streams fed from melting ice and snow are a principal source not only of water but also of hydro-electricity, the problems of just how much snow and ice exists and how much melt water can be expected in any particular season are of great importance in planning future needs.

In order to systematize the study of these problems, the International Hydrological Decade co-ordinating council, through the Scientific Committee on Water Research (COWAR) of the International Council of Scientific Unions (ICSU), has passed several resolutions concerning glaciological problems, and the Commission of Snow and Ice of the International Association of Scientific Hydrology has made plans to put these resolutions into effect. In many cases considerable progress has been made, and documents are available setting out just what should be done in order to provide the necessary information.

Permanent Recording

One important requirement is for all nations which have permanent ice and snow, whether above the surface of the Earth or within it, to record what they have, and for this purpose a working party under Professor F. Muller (McGill University, Canada) has prepared a guide to a world inventory. This suggests that the inventory be conducted at two levels of sophistication, and that the results should be prepared in a digital form suitable for storage and handling by computer.

The technique has been tested by three pilot studies using the suggestions for the glacier inventory in three areas of different nature, and results of these pilot studies were reported at the General Assembly of the International Association of Scientific Hydrology at Bern last autumn. The first area was the south-west part of Axel Heiberg Island in the Canadian High Arctic, a region with moderate mountain relief and many different types of cold glaciers. Some 250 glaciers were included in that study. The second region was in the Waputik Range in the Canadian Rocky Mountains, where a number of valley glaciers descend from three small ice fields and where there are numerous cirque glaciers and glacierets. About 100 glaciers were included in that survey. Finally, there was the region of Mount Everest in eastern Nepal, where most valley glaciers are fed by avalanches from precipitous slopes and where the ablation areas are often thickly covered with debris. Some 450 glaciers were included in this study. For each glacier a data sheet was filled in which identified and classified the glaciers and then gave its vital statistics such as elevation range, length, maximum width, area, elevation of snow-line and so on. This information was then put into a computer format for use on an IBM 7040/7044 computer which allows 131 characters per line; in the lower degree of sophistication each glacier required two lines. On the basis of the experience of these pilot studies and of the comments of other experts on the draft, a final version of this guide has now been prepared.

It is hoped that, with this guide available, there will be a great increase in the available data on glaciers and permafrost. Three volumes of the catalogue of glaciers of the USSR have already been published, and similar work is going on for the French Alps. It is necessary that this work be undertaken by all countries with glaciers or permafrost on their territory. If this can be achieved, we can improve greatly on the present position where estimates of the area outside the polar regions covered by ice vary by more than 20 per cent.

Another obvious requirement is to measure and map seasonal snow cover, and a working group under Dr M. de Quervain of the Swiss Federal Avalanche Research Institute has been preparing a guide to enable people with relatively little experience to make worthwhile measurements which will be comparable from place to place. One of the requirements is to give clear definitions of the terms involved (just what is meant by snow-line, for example), and another is to give simple methods for measuring the total storage of water in a snow cover. A similar problem arises in the case of sea, lake and river ice, and a guide is also being prepared by a working group, under Dr E. R. Pounder of McGill University, to cover these fields.

Glacier Fluctuation

A further resolution of the IHD co-ordinating committee concerns a study of the fluctuations of glaciers. This is a field with a much older history. Observations of the advance and retreat of glacier fronts have been made for many years in many parts of the world, and the gradual development of co-ordination in this field has culminated in the recent establishment of a permanent service under FAGS (Federation of Astronomical and Geophysical Services). Ing. P. Kasser (Swiss Federal Institute of Technology) has produced the first report of this service recently. The chief development since the early international reports has been the increase of interest in changes of thickness and of mass balance of glaciers as well as of their lengths

Another project, in many ways the most ambitious, calls for combined water, ice and heat balance studies at selected glacier basins A working group under Dr M F Meier, the present president of the Commission of Snow and Ice and a member of the US Geological Survey, has selected three chains of stations The first stretches north and south through the Americas and into the Antarctic Peninsula, a second runs east–west from Tien Shan in Soviet Central Asia through the Caucasus and Alps, with further points in Canada and the Pacific Northwest of the United States, while a further chain, also roughly east–west, goes through the Polar Urals, Scandinavia, Iceland, Greenland and the Canadian Arctic to Alaska At each of the selected basins it is hoped to have a comprehensive set of measurements to cover all three balances—of ice, run-off water and heat—so that their interdependence can be studied Some countries are already doing a lot of this, about 30 of the stations being in operation in 1965–66, but often there is one of the elements left out By emphasizing the need for all to be measured on the same basins, it is hoped to encourage national authorities to support a really comprehensive programme

Polar Ice

The worst gap in our knowledge concerns the ice in the polar regions It is not known at present whether the amount of ice in either of the great ice sheets in Greenland and the Antarctic is increasing or decreasing In the case of Greenland, work at present being done by the International Glaciological Greenland Expedition may provide the answer, but for the Antarctic an even larger programme of work will be needed With the aim of preparing a co-ordinated programme for the International Hydrological Decade in Antarctica, the working group on glaciology of the Scientific Committee on Antarctic Research (SCAR) has prepared a document for the hydrological evaluation of glaciological research programmes in Antarctica. This document is also now being considered by COWAR and the IHD Co-ordinating Council

Two future international conferences are planned to discuss scientific matters concerned with these programmes Both are co-sponsored by the Commission of Snow and Ice The first, of which the other co-sponsor is SCAR, will be an International Symposium on Antarctic Glaciological Exploration, it will be held in Hanover, N H, USA, in September 1968 The second, co-sponsored by the Glaciological Society, is on the Hydrology of Glaciers, and will be held in Cambridge, England, in September 1969

It is plain that much of this work is still at the planning stage The manuals are in the final stages of preparation and the stage is set for a big increase in our systematic knowledge of the ice on the Earth The extent to which these plans will result in a completed programme will depend very largely on the extent to which the authorities in different lands realize the great advantages of knowing just what resources of water there are tied up in their seasonal and permanent snow and ice, and therefore make available the relatively small amounts of money and manpower necessary to do the work Persuading people of the importance of this is what the International Hydrological Decade is about

I would like to thank Dr M F Meier and Dr F Muller for commenting on a draft of this report, and also Professor H Hoinkes, the president of the Commission of Snow and Ice from 1963–67, for letting me see the manuscript of his presidential address to the Commission last September, in which he reviewed the position of glaciology in the International Hydrological Decade at greater length[1]

Feasibility in Age Research

by

A. COMFORT

MRC Research Group,
University College,
London

The present state of knowledge and the potentialities of the subject seem to justify fundamental research into the process of ageing.

In several countries investment decisions are now being taken, or are about to be taken, about future support for research into problems connected with the process and manifestations of human ageing The desirability and possible scope of an institute of age studies are under informal discussion with British universities and donors, and a committee of the United States Senate is receiving evidence with a view to planning future research policy

Developed countries have an increasing proportion of old citizens whose medical and social needs require study and palliation, and call for an increasing volume of *ad hoc* research At the same time, where a fundamental process is probably comprehensive and possibly controllable, reasonable support for a radical attack on the biology of that process offers a chance (if the attack succeeds) of shortcircuiting much piecemeal investigation or (if it succeeds to the point of comprehending a process which then appears fundamentally or practically uncontrollable) of avoiding misplaced research.

The aims of ageing research are presumably (*a*) to comprehend and if possible palliate the disorders which affect old human beings, and (*b*) to interfere, fundamentally if possible, with the "clock" which determines timewise loss of vigour either by spinning out the entire process of cradle-to-grave development, so that, without reducing physiological activity, it occupies more years· or better, to produce an effect opposite in sense to the effect produced in mice by chronic low-dose irradiation or a single large dose in early life. These procedures appear to lop off a portion of the plateau of adult vigour proportional to the dose it is an open question whether this represents an intensification of the same processes which are seen in normal ageing, or only a simulation.

An ideal "remedy" for senescence would have the reverse effect, of prolonging the same plateau, so that the vigour and disabilities of a treated individual of 85 would resemble those of an untreated individual of 80, the effect being produced across the board and without reference to particular genetic constitutions or causes of death. While remedies depending on unknown biological facts cannot be synthesized to order, this appears to be the objective of choice provided that it is not manifestly impracticable on a basis of existing knowledge.

Projects based on the prolongation of life by interrupting bodily function (artificial hibernation, cold storage) complete the list of theoretically possible approaches, but have little practical appeal outside the field of long-distance space travel. Current priorities and predictions, for British research at least, should be drawn from less paranoid fields. In these it is desirable not only to plan research for feasibility, but to predict possible changes in demographic requirements which may, eventually, result from the research of others, should we fail to give our own biologists the support needed to make the relevant advances themselves.

Wider scientific and public discussion of the prospects and direction of research into ageing is needed now, because the present state of the subject is not widely known to scientists outside the field, and planning decisions can easily be influenced by the optimistic or pessimistic tone of single theorists or papers. Research planners require to know whether or not there is a reasonable prospect in the near future of identifying a single leading process in mammalian ageing which might be open to useful interference. The consequences would be similar to those observed in the dietary retardation of rodents, that is, a postponement of death from all causes or, better, a generalized retardation of all age-associated deteriorative processes leading to a longer period of adult vigour. If there is not, or if the "leading process" is, for example, one of exposure of un-eliminated late-acting genes, or otherwise an evolutionary or statistical process only, research money would better be applied to prosthetics and geriatrics, the piecemeal alleviation of senile disabilities.

If, as I believe, the first of these alternatives is probable but by no means certain, the highest immediate research priority is to concentrate resources on research designed to distinguish between them.

I suggest that a choice between these hypotheses could be made within a reasonably short period of time, and that in view of the consequences for our long-term planning of age research, this choice should be an immediate research priority.

In the early years of the present century it was a reasonable expectation of medical researchers that the "cause and cure" of cancer (meaning the malignancies in general) might, with reasonable application, be discovered within a short time—on the model of earlier discoveries of the cause of bacterial infections. A Nobel Prize was even awarded for the discovery of such a cause—prematurely, as it appeared. Such expectations, which formed the early years of "cancer research", no longer retain credibility in quite this form against the background of wider understanding.

It is necessary to ask whether there should be a similar reappraisal of the aims of research into the nature and control of human ageing. A less popular topic than cancer research, gerontology too was begotten in simplistic optimism when Brown-Séquard attempted to rejuvenate himself with testicular extract. Although the possibility of a single large-scale influence on the realizable human lifespan cannot be excluded, on the basis of what is now known, most workers would today consider the picture of mammalian senescence to be at least as complex as that of malignant change, and some, on evolutionary or genetic grounds, have suspected that it may be practically or essentially unmodifiable by reason of diversity[1,2]. If the 'loss of programme" which increasingly upsets homoeostasis with age represents the accumulation of postponed genetic effects inaccessible to selection, this pessimism would be justified. It may be that natural selection has increased lifespan where necessary, not by increasing the reliability of cellular stability but by providing fallback "patch" mechanisms to compensate for disadaptive unreliability[3]. Such an expedient would itself result in a divergent system, like the borrowing of money to repay creditors, and one very difficult to stabilize artificially.

Judging by recent congresses and publications, most research gerontologists now have a leading general hypothesis of ageing—that it is a cellular information loss, probably in fixed cells, and originally at the molecular level, dyshomoeostasis of other kinds through loss of neuronal, endocrine and immunological information being secondary. This theory is based on the natural history of ageing in organisms generally, on radiation biology, and on stochastic mathematics applied to the life-table. The information-content of fixed-cell DNA at successive ages has not been measured, and so the theory may be wrong, but it must now be demonstrated or disposed of.

If molecular information-loss is the timekeeper of ageing, there are by consensus two hypotheses to explain its occurrence: (*a*) that it is caused by the random accumulation of chemical noise in the cellular information system, and is itself unprogrammed, (*b*) that it is a built-in consequence of differentiation, caused by the switching-off of synthetic processes which cannot be switched on again without loss of differentiation, or to the evolutionary accumulation of late-acting deleterious genes.

Prediction in age studies is closely involved with these hypotheses, which are not mutually exclusive, and it is now highly important to examine and dispose of them. If human ageing as observed in the intact subject is not timed by genetic information loss, the nature of its leading "clock" and the accessibility of this to interference remain wide open. If it is so timed, and hypothesis (*a*) is correct, the likelihood of successful interference with the underlying random process is reasonably high. Suggested sources of random damage include "hits" by radiation[4,5], cross-linking and colloid changes[6-8], free-radical effects generally[9], and release of lysosomal DNases[10,11]. All these are observable and, in model systems, modifiable. Another consequence of hypothesis (*a*) is that it does not exclude at least a useful identity between the causes of ageing, for example, in insect imagos and those observed in mammalian fixed cells, with an increase in the number of possible test systems available. The identity of low-dose radiation-induced life shortening with accelerated ageing remains a matter of controversy. The resemblance is close but not complete[12], attempts to see whether radioprotectants abolish the life-shortening effect of chronic exposure to low doses run into practical problems of maintaining drug-level with the agents now in use, and no conclusive results have been published. Accumulation of somatic point mutation, which was at one time favoured as an explanation of ageing, is now largely excluded on statistical and genetic grounds[13,14] as well as by the failure of chemical mutagens to produce radiation-like life-shortening unless they are also capable of causing damage more extensive than point mutation—particularly crosslinking[13]. Where, as in numerous papers by Curtis[15,16], "mutation" is adduced as a source of programme noise in ageing cells, the term is used to include breakage, deletion and operon loss generally. Although the rate of increase in chromosomal abnormalities is greater in short than in long-lived strains[17], the only age phenomena which seem likely to be explicable in terms of one or more point mutations are autoimmune divergence[3,11,18-20] and possibly some factors in malignancy[3,11,21]. Radiation-type life-shortening can be induced in adult *Drosophila*, which are resistant to low doses of radiation, by feeding amino-acid analogues during larval life[8,22], before the postmitotic state is reached

Hypothesis (*b*) has been most fully stated by Medvedev[23] It implies that the suppression of information or synthetic capacity which upsets homoeostasis and leads to ageing is itself a necessary process in differentiation. If this is so, the prognostic consequences are considerable. It does not mean that artificial "stretching" of the human lifespan is impossible, but that the only likely way of prolonging vigour will prove to be through stretching the development programme as a whole, on the analogy of rodent dietary restriction Such stretching would be biologically drastic, and would include (or even be confined to) the prolongation of immaturity, rather than the preservation of "adult vigour" as a steady state —which, on hypothesis (*b*), it is not

Medvedev's argument includes a revival of the Weismannian idea that life-limitation might itself be an evolved adaptation, which has provided the organism with a destructor mechanism in the form of noise-generating genes Evolutionary jobbing-backward in relation to observed lifespans is particularly unrewarding, and I have already argued that the Weismannian advantages of senescence to a species depend on a circular argument[24], although a contrary view has been developed by Sacher[25] Noise-generator genes might or might not be accessible to interference, and it seems as likely that the evolved attribute limiting lifespan, if such there be, is the general stability of the informational system to noise-accumulation at this point the argument approaches Pangloss's theorem Leaving this aside, we are left with two questions which influence our expectation of probable interference with the rate of human senescence Is mammalian dyshomoeostasis with age timed by loss of molecular information ? If so, is this loss a result of random noise-accumulation, in fixed or in clonally replicated cells, or of the finitude of the switching-sequence involved in epigenetics, or of both ?

Until these questions are resolved, further research on ageing and the likelihood and extent of any control of the human lifespan can only be assessed "blind", and so the immediate programme of age research needs to be directed to them There is a fair body of evidence in favour of the concept of information loss, and of that loss being random in character, but there is a methodological bias in favour of these conclusions built-in by the involvement of age studies with radiation effects (which may not be analogous to natural ageing) and the mathematical preoccupations of radiobiologists Direct examination of the functioning of fixed-cell DNA by the detection of nonsense-materials[26] or by the evidences of compensatory synthesis to keep up with failing accuracy of copying[27-30] is already in hand, on the lines originally suggested by Maynard Smith[14,27,31] Production of nonsense materials, if demonstrated, would accord better with stochastic damage than with the switching-off of genes The only conclusive short-cut experiments are those which might point the way by demonstrating that cellular information can be protected, through the study of substances which prolong the life of fixed cells The complementary demonstration, depending on life-shortening[22], is inconclusive for obvious reasons Attempts to prolong mammalian life with antiradiation drugs and antioxidants have so far been unsatisfactory[9] in execution rather than in conception Apart from the papers of Harman[32], whose longest-lived mice on antioxidants failed to equal the best untreated performance for the strain, the single, and relatively small, prolongation in lifespan so far reported in mammals followed the administration of an immunosuppressant[33]

There is available a repertoire of treatments which could, if the practical difficulties of administration to a suitable and standardized organism can be overcome, dispose both of the general hypothesis of noise-accumulation, and of sub-hypotheses concerning the parts played, for example, by cross-linking, lysosomal DNase, and consequent autoimmune phenomena

If it could be shown that a theoretically accountable substance (antioxidant, anti-cross-linking agent, DNA ligase potentiator or lysosome stabilizer) is capable of prolonging the mature lifespan of a simple organism beyond the maximum normally observed in outbred individuals, this would in itself constitute a useful advance Demonstration of Medvedev's alternative hypothesis would involve considerably subtler techniques, recent work on serial gene expression in ciliates[34] foreshadows these, and indicates that the hypothesis could be extended from fixed cells to clones Meanwhile the whole question of clonal stability in somatic cells, an old gerontological source of optimism dating from Carrel, remains open.

Concentration of fundamental projects in these questions could at least dispose of them, and a concerted attack on these lines seems desirable—gerontology at the moment has more bricklayers than architects, and the most important new evidence might well come from outside the circle of age researchers, provided the general biologists in other fields are aware of the situation In view of the importance of work on cellular information and epigenetics to biology as a whole, there is little risk of wasting a research investment at such a fundamental level If within 10 years it has become evident that protection of cellular information at the level demanded by "adult vigour", or useful stretching of development to extend that vigour, is fundamentally or practically unlikely in man, researchers on age processes would at least be released to pursue palliative concerns, such as the re-examination of autoimmune divergence or the correction of hormone deficits, traditional topics of gerontology which in any case require re-examination, while the chances of a degree of control over the timing and sequence of age changes as a whole seem at least good enough to merit a substantial and co-ordinated effort on a world basis

Palaeomagnetism, Potassium–Argon Ages and Petrology of some Volcanic Rocks

by
G. BRENT DALRYMPLE
ALLAN COX*
US Geological Survey,
Menlo Park,
California

Geological evidence obtained from samples of rocks from Cocos Island, Costa Rica, seems to agree with the idea that this island could have been a stepping stone for organisms migrating to the Galapagos Islands

Cocos Island lies in the eastern Pacific Ocean on the crest of the Cocos Ridge, a well defined linear bathymetric high with an average depth at its crest of about 1,000 fathoms[1] Extending south-west from Costa Rica to the Galapagos Islands, where it joins the Galapagos Fracture Zone, Cocos Ridge appears to be a fracture zone similar to the Tehuantepec Ridge, which branches from the Clipperton Fracture Zone, and to the Nasca Ridge, which branches from the Easter Island Fracture Zone. The age of Cocos Island is of geophysical interest as an indication of the age of the volcanism associated with the fracture zone, and as a measure of the minimum age of the sea floor in this tectonically active region The age is also of biogeographical interest because of the possibility that Cocos Island served as a stepping stone for plants and animals migrating to the Galapagos Islands from Central America The visit of the Galapagos International Scientific Project to Cocos Island on March 8–9, 1964, gave one of us (A C) an opportunity to collect rock samples in the vicinity of Chatham Bay (Fig 1) The results of potassium–argon age determinations, palaeomagnetic measurements and chemical analyses are reported here

In spite of more than 400 treasure-seeking and scientific expeditions to Cocos, surprisingly little is known about its geology Merrill[2] published a description and partial chemical analysis of an "andesite" collected by Agassis from the vicinity of Chatham Bay Chesterman[3] described two olivine basalts, one latite, one lapilli tuff-breccia and one "oligophyre" composed mostly of oligoclase, collected on earlier expeditions The most complete report of the geology of Cocos is that of Chubb[4], who spent 24 h there in 1924 He noted that the island was composed chiefly of massive lava flows and described an agglomeratic tuff from the south side of Wafer Bay From a study of beach pebbles collected near Wafer Bay, he concluded that the rocks there are principally labradorite–andesite and hornblende labradorite–andesite Chubb presented chemical analyses of two typical specimens and described them as similar to those of the Galapagos and especially of Rapa Macdonald[5], however, recognizing the inadequacy of the geological information from Cocos Island, did not include the Cocos rocks in the mid-Pacific volcanic province

The botanist Alban Stewart found that the flora of Cocos was that of a typical oceanic island, and that there was no botanical evidence for a land bridge connecting Cocos with the Galapagos Islands[6] He concluded that Cocos Island was younger than the Galapagos Islands because the percentage of endemic plants is smaller, an argument that seems tenuous in view of the fact that Cocos is only half as far from the mainland, has a different climate and is in different oceanic and atmospheric current systems Vinton inferred a Pleistocene age for the island from the thinness of the soils, the ungraded character of the streams and the scarcity of beach deposits[7] He further concluded that, during the Oligocene and Miocene, Cocos Ridge was a peninsula extending from Central America to within less than 200 km of the Galapagos Islands but that the peninsula submerged well before the formation of Cocos Island Channels have been discovered on the sides of Cocos Ridge, but Wilde[8] concluded that these were formed by turbidity currents rather than by subaerial erosion Furthermore, the crust underlying the ridge seems to be oceanic rather than continental[9], and the absence of guyots on the ridge indicates that it has remained submerged at least since the time of the volcanic

* Present address Stanford University, Stanford, California.

activity that produced the numerous seamounts on the ridge[10].

The rocks in the vicinity of Chatham Bay, like those studied by Chubb at Wafer Bay, include flows, tuff and agglomerates. East and south of Chatham Creek the flows are thick, massive and nearly horizontal and seem to extend several kilometres along the coast These flows are capped by a thick sequence of volcanic ash in the basin at the head of Chatham Creek In contrast, the flows north of Chatham Creek are thin and are interbedded with crystal lithic tuff probably of subaerial origin. Most of these flows dip seaward away from present topographic highs, suggesting initial dip rather than deformation The northern tip of Cocos consists of bedded tuffs that dip northward Nuez Island is composed primarily of agglomerates, which also dip northward away from the central mass of Cocos, but there the dips are sufficiently steep to suggest the possibility of some deformation

diopsidic augite The plagioclase phenocrysts are complexly twinned and strongly zoned, most of them are labradorite (An$_{55-65}$), but a few are as calcic as An$_{80}$ The groundmass is composed of plagioclase of composition An$_{40-45}$, olivine, diopsidic augite, iron–titanium oxides and apatite. Almost all of the olivine is altered to iddingsite A modal analysis of sample 4C401 gave 56 per cent plagioclase, 18 per cent pyroxene, 13 per cent olivine, 11 per cent opaque minerals and 1 per cent apatite The chemical analyses of these three rocks also do not differ significantly (Table 1). They all contain less than 50 per cent silica, a relatively large amount of alumina and total alkalis, and are oxidized, as can be seen by their high Fe$_2$O$_3$/FeO ratios More than 1 75 per cent titania is present, which is typical for oceanic basalts in contrast to circumoceanic basalts, which usually contain less TiO$_2$ (ref 11).

Sample 4C400 from one of the thick massive flows is a slightly porphyritic, granular trachyte that consists primarily of sodic plagioclase and sanidine with small amounts of olivine (altered to iddingsite), hypersthene, iron–titanium oxides and apatite Petrographically and chemically, it resembles the specimen from Chatham Bay described by Merrill[2] as an andesite

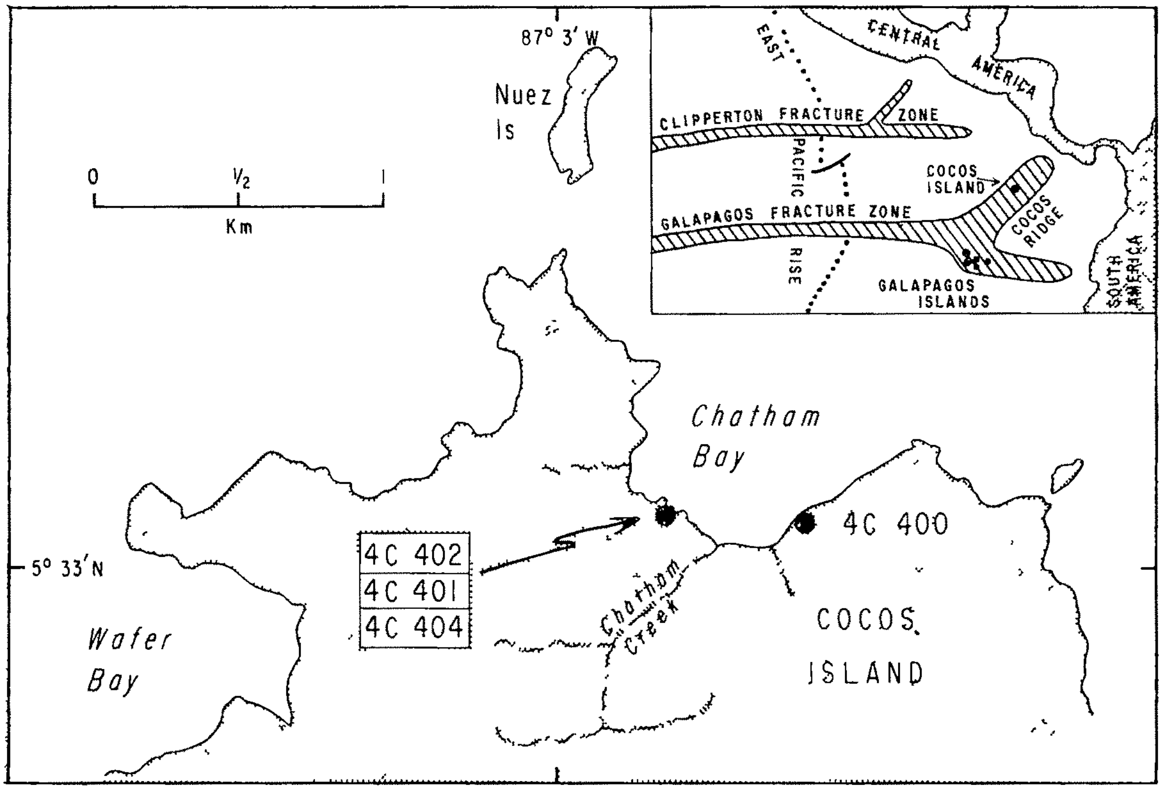

Fig 1 Index map of northern Cocos Island showing locations of analysed samples Samples north-west of Chatham Creek are shown in stratigraphic order Inset shows the relationship of Cocos Island to the bathymetric features discussed in the text

The marks of extremely active erosion characterize the present surface of Cocos Island Despite the rapid growth of vegetation, many landslide scars are present in the vicinity of Chatham Bay Mudflow and landslide deposits clog the lower reaches of the steeply incised canyon of Chatham Creek, and fans containing subangular boulders up to 2 m in diameter extend into the bay at the mouth of Chatham Creek, indicating that there has been recent mudflow activity

For this study, samples were collected from thin flows north of Chatham Creek and from one of the thick, massive flows on the south side of Chatham Bay (Fig 1) Samples 4C401, 4C402 and 4C404 from three of the thin flows are nearly identical alkali olivine basalts These samples are porphyritic with a trachytic texture and contain phenocrysts of plagioclase, olivine and, rarely,

The alkali basalts which were studied are plotted on a K$_2$O–SiO$_2$ diagram (Fig 2) together with previous analyses by Chubb[4] The analyses all fall within the field of the alkali oceanic basalts[12] No tholeite has been reported from Cocos Island The alkali basalts compare closely in composition with average "oceanic" alkali basalt[12], and A E J Engel and C G Engel[13] have pointed out that rocks of this composition predominate on the islands and the upper parts of seamounts associated with the East Pacific Rise Petrologically, Cocos Island is thus

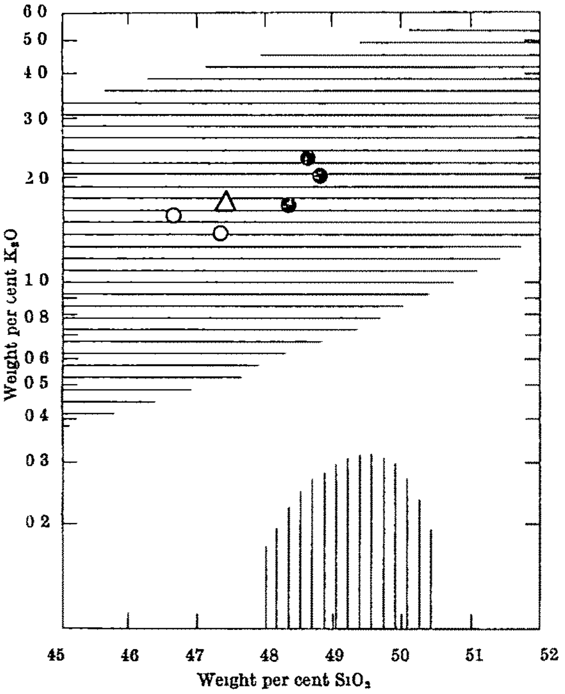

Fig 2 K_2O–SiO_2 diagram for rocks from Cocos Island Solid circles are analyses from this study, open circles are data from Chubb[4], and triangle is average oceanic alkali basalt[13] Vertically and horizontally ruled areas are approximate fields of the oceanic tholeiite and alkali basalt[13]

oceanic, strengthening the conclusion that Cocos Ridge is not a submerged part of the continent

The polarity of four or more oriented samples from each flow was measured in the field with a portable fluxgate magnetometer[14] and found to be internally consistent These field measurements were confirmed by remeasuring the remanence of one sample from each flow in the laboratory[15] and checking its magnetic stability in alternating magnetic fields[16] (Table 2) The three flows north of Chatham Creek are reversely magnetized (Table 2) Two of these, flows 4*C*401 and 4*C*402, are underlain by baked tuffaceous material that is also reversely magnetized, indicating that the reversed remanent magnetism is a result of reversals of the Earth's field and not mineralogically controlled self reversal The massive trachyte flow (4*C*400) is normally magnetized The intensity of magnetization of the alkali olivine basalt samples is typical of basalt[17], whereas that of the trachyte (4*C*400) is much smaller This is probably because the trachyte contains fewer grains of iron oxides

An examination of thin sections showed that three of the four flows were suitable[18] for whole-rock potassium–argon age measurements Argon analyses were by standard isotope dilution techniques using methods and techniques previously described[10] Potassium was determined by flame photometry using a lithium internal standard The ages (Table 3) of flows 4*C*401 and 4*C*402 are consistent with their stratigraphic relations, and the ages of all three flows are tightly grouped near 2×10^6 yr

Recent studies of the history of geomagnetic reversals indicate that the polarity structure consists of polarity epochs, which are periods of time during which the Earth's magnetic field was predominantly or entirely of one polarity, and polarity events, which are like epochs but of much shorter duration[20–22] One of the best documented events is the Olduvai normal event which occurred about 2 0 to 1 9×10^6 yr ago The normal polarity of this event is recorded (Fig 3) in lava flows from Olduvai Gorge, Tanzania[23–24], the Pribilof Islands, Alaska[25], Réunion Island in the Indian Ocean[26] and Victoria, Australia[27] From the polarity and age of sample 4*C*400, Cocos Island also appears to be a locality where volcanism occurred during the Olduvai event The duration of the Olduvai event has been estimated to be about $0{\cdot}14 \times 10^6$ yr (refs 28 and 29), whereas the spread in potassium–argon ages is nearly twice this Although undoubtedly partly caused by dating errors, the spread in ages suggests that the Olduvai event consists of multiple, widely spaced shorter events, for which some evidence has already been found in deep-sea sediment cores[29].

Table 2 PALAEOMAGNETIC DATA FOR ROCKS FROM COCOS ISLAND

Sample No	Original magnetization D	I	J	After partial demagnetization D	I	J	Polarity
4*C*400	003°	21°	$8\ 02 \times 10^{-4}$	008°	24°	$2\ 97 \times 10^{-4}$	Normal
4*C*401	182°	00°	$2\ 51 \times 10^{-3}$	182°	06°	$1\ 61 \times 10^{-3}$	Reversed
4*C*402	173°	−07°	$2\ 41 \times 10^{-3}$	173°	−08°	$1\ 20 \times 10^{-3}$	Reversed
4*C*404	170°	−01°	$4\ 27 \times 10^{-3}$	170°	−01°	$2\ 30 \times 10^{-3}$	Reversed

D, Declination, I, inclination, J, intensity in emu/cc.

Partial demagnetization was in a c field of 400 gauss

Table 3 ANALYTICAL DATA FOR POTASSIUM–ARGON AGE DETERMINATIONS ON VOLCANIC ROCKS FROM COCOS ISLAND, COSTA RICA

Sample No	K_2O (per cent)	Sample weight (g)	Argon Ar^{40}_{rad}/g (moles)	$\frac{Ar^{40}_{rad} \times 100}{Ar^{40}_{total}}$	Calculated age* (10^6 yr)
4*C*400	4 78, 4 81	9 956	$1\ 480 \times 10^{-11}$	62 8	2 09 ± 0 04
4*C*401	2 12, 2 13	10 000	$0\ 637 \times 10^{-11}$	25 9	2 03 ± 0 06
4*C*402	2 22, 2 22	8 624	$0\ 632 \times 10^{-11}$	19 0	1 93 ± 0 09

* $\lambda_\varepsilon = 0\ 585 \times 10^{-10}\ yr^{-1}$, $\lambda_\beta = 4\ 72 \times 10^{-10}\ yr^{-1}$, $K^{40}/K = 1\ 19 \times 10^{-4}$ mole/mole

The ± values are estimates of the analytical precision at the 68 per cent confidence level[26]

Analyses were made on whole-rock samples

In a similar study on the Galapagos Islands[30] we found that volcanism began at least 2 4×10^6 yr ago and has continued to the present time Thus there is at least some overlap between the volcanic activity on the Galapagos Fracture Zone and that on the Cocos Ridge On

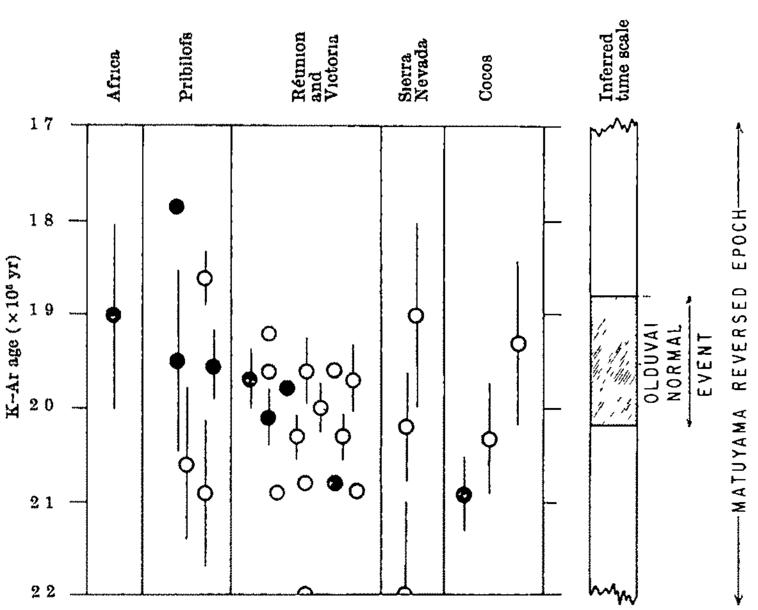

Fig 3 Comparison of data from Cocos Island rocks with worldwide palaeomagnetic–radiometric data from rocks having ages between 1 7 and 2 2×10^6 yr (refs 23–27) Solid circles indicate normal polarity, open circles indicate reversed polarity, and vertical bars are estimates of standard deviation of analytical error where available

both Cocos and the Galapagos Islands, it is possible that older rocks may exist beneath a surface cover of younger flows, so that the time when individual islands first emerged from the sea cannot be determined with certainty The geological evidence, however, does not contradict the idea that Cocos Island may have served as a stepping stone for organisms migrating to the Galapagos Islands, even though it is unlikely that the Cocos Ridge was ever a land bridge

We thank Edward Mankinen and Wilfrid Davis for assistance with the palaeomagnetic and potassium–argon measurements Chemical analyses were under the direction of Leonard Shapiro This work and the Galapagos International Scientific Project were supported by grants from the US National Science Foundation

The opacity of the galaxy to soft X-rays may be less than previously supposed This may permit a variety of extragalactic objects to be observed at ~ 50 Å Some implications of this situation are discussed here

WE wish to discuss in this article some astrophysical implications of soft X-ray observations Our discussion is motivated by new evidence which indicates that the galaxy may be more transparent to X-rays than was previously believed, and that extragalactic radiation of wavelength ~ 50 Å (or even longer) may penetrate to us without severe attenuation

The X-ray opacity of the galaxy is straightforwardly related to the column density of matter along the line of sight It has traditionally been thought that 21 cm radio measurements yield a direct measure of the column density of hydrogen atoms· the optical depth of the galaxy to X-rays can then be calculated, making allowance for contributions from molecular hydrogen, from helium, and from heavy elements in interstellar space This calculation leads to the conclusion that the optical depth at 50 Å $\gtrsim 1$ in almost all directions There is now, however, some evidence which suggests that the amount of hydrogen in interstellar space may be significantly lower than the value inferred from 21 cm data Some recently obtained ultraviolet spectra of stars in the direction of Orion reveal that the Lyman α absorption line is surprisingly narrow[1] Fischel and Stecher[2] have made a proposal which may resolve the discrepancy They show that "pumping" by blue-shifted Lyman α radiation can lead to population inversion in the hyperfine states of atomic hydrogen. Because 21 cm radiation would be amplified by the ensuing maser action, a lower column density of hydrogen is then needed to produce a given intensity in the 21 cm line

Further evidence that the interstellar hydrogen density may be lower than the conventional estimates was recently reported by Bowyer, Field and Mack[3], who have measured the X-ray flux in the 44–70 Å range over a wide area of sky They have discovered a background flux, stronger towards the Galactic Pole, which probably originates outside the galaxy If this flux is truly isotropic (as is the X-ray background at shorter wavelengths), the observed latitude dependence indicates that the opacity of the galaxy should be about three times lower than the usual estimates In consequence, the optical depth at 50 Å would be $\lesssim 1$ over a wide area of sky at high galactic latitudes Although the optical depth goes roughly as λ^3, observations at even 100 Å may be feasible in certain directions where there are "windows" in the hydrogen density. Our aim in this article is to emphasize the potential importance of very soft X-ray observations. While it will clearly be valuable to extend the spectra of non-thermal X-ray sources towards longer wavelengths, the chief interest of such observations lies in the possibility of detecting thermal emission by hot gas. Whereas such gas would need to have a temperature approaching 10^7 °K to be detectable at wavelengths shorter than 10 Å, very soft X-ray observations may reveal thermal sources at $\sim 10^6$ °K. Moreover, absorption by diffuse intergalactic matter may become detectable. We shall also make some tentative inferences from the results of Bowyer, Field and Mack, which provide the only published information on ~50 Å X-rays.

---

* On leave from the Institute of Physics, University of Bologna

Diffuse X-ray Background and Intergalactic Absorption

Bowyer *et al.* observed an X-ray flux near the Galactic Pole of $\sim 5\times10^{-25}$ erg cm^{-2} sec^{-1} ster^{-1} (Hz)$^{-1}$ at ~44 Å (uncorrected for galactic absorption). Even according to the conventional estimates, the optical depth of the galaxy is only ~1 in this direction. Unless this is a serious underestimate, we can set a limit to the intensity of background X-rays incident on the galaxy, and we can infer that, if the density of the intergalactic medium is $n\sim10^{-5}$ particles cm^{-3}, its temperature T must satisfy $T(z)\lesssim 5\times10^5\,(1+z)^\circ$ K at all red-shifts z.

A background flux of X-rays with a spectrum $\nu^{-\alpha}$, with $\alpha\sim1\cdot2$, is known to exist at shorter wavelengths[4]. This background is isotropic to within 10 per cent, and is probably universal. It has been commonly interpreted as inverse Compton radiation resulting from scattering of the primeval black-body radiation by relativistic electrons[5,6]. If this interpretation is correct, the spectrum would be likely to maintain the same slope right down to the very soft X-ray range. (A spectrum which flattens at longer wavelengths could be explained, but a steepening would not be expected.) A straightforward extrapolation of the observed X-ray background spectrum to ~50 Å leads to a flux of the order of three times greater than that observed by Bowyer *et al.* We can therefore conclude that either (*a*) the optical depth of the galaxy at ~50 Å does indeed have the conventionally assumed value ~1 at high galactic latitudes, and we are observing a background flux with a straight power-law spectrum*, or (*b*) the opacity of the galaxy is lower, but the background has a spectrum which flattens at long wavelengths, either intrinsically or because of extragalactic absorption. In both cases it follows that the optical depth of the intergalactic medium to soft X-rays is $\lesssim 1$, out to a red-shift of at least $z\sim1$. As Bowyer *et al.* point out, this implies that, for $n\sim10^{-5}$ particles cm^{-3}, hydrogen and helium must be at least ~99 per cent ionized. If the ionization is collisional, this requires $T\gtrsim1.5\times10^5$ °K at least out to $z\sim1$.

An interesting limit can also be set on the abundance of heavy elements in intergalactic space. If all elements are present with their "cosmical" abundance in a cool gas, Bell and Kingston[7] have calculated that the heavy elements contribute about 50 per cent as much as hydrogen and helium together to the opacity at ~50 Å (and proportionately more at shorter wavelengths). Whereas the intergalactic gas can be hot enough for hydrogen and helium to be almost completely ionized, however, it cannot (if $n\sim10^{-5}$ particles cm^{-3}) be hot enough to strip the heavy elements of their K-shell electrons which are responsible for the X-ray opacity. If the optical depth $\lesssim 1$, heavy elements in intergalactic space must have less than 2 per cent of their "cosmical" relative abundance (with correspondingly weaker limits if n is lower). We would not expect them to be present with their full local abundance relative to hydrogen[8], but this is nevertheless a highly significant result, because it sets a limit to the cumulative contamination of intergalactic space by galaxies and exploding objects during the life of the universe.

If the inverse Compton explanation for the X-ray background is the correct one, it is probable that most of the observed X-rays were emitted at very early epochs corresponding to $z\gtrsim5$ (ref. 6). This is because the black-body radiation would then have been more intense, and also because radio sources (and thus presumably relativistic electrons) may have been produced more profusely in the past[9]. We may therefore be able to set limits on the opacity of the intergalactic gas at these very large red-shifts, which would be especially interesting because all the other direct evidence for the state of ionization of intergalactic gas—the absence of Lyman α absorption in the spectra of quasi-stellar objects[10], and the 21 cm observations[11]—refers only to $z\lesssim2$. In calculating the absorption at very large red-shifts, we must allow for the facts that $n\propto(1+z)^3$, that the cross-section for absorption of a photon of observed wavelength λ by hydrogen or helium atoms is roughly proportional to λ^3 (that is, to $(1+z)^{-3}$) and that the effective path length (in the Einstein–de Sitter model) $\propto(1+z)^{3/2}$. As a result of these effects, we can only conclude that the degree of ionization of hydrogen and helium is >95 per cent for $z\sim2$–5—a rather less sensitive result than for smaller red-shifts. We still obtain an upper limit of ~2 per cent for the heavy element abundance relative to its "cosmical" value, however (if $n\sim10^{-5}$ cm^{-3}), because absorption by these elements is relatively more important at shorter wavelengths.

If an accurate spectrum of the X-ray background between, say, 1 Å and 50 Å were available, we might be able to decide whether the long wavelength flux is reduced by intergalactic absorption, and, if so, where the absorption is taking place. The possibility that the intergalactic gas was highly ionized at epochs corresponding to $z\sim5$, implying that $T\gtrsim2.5\times10^5$ °K, is an interesting further constraint on its permitted thermal history. It would also imply that radio waves from distant sources had an appreciable chance of being Thomson scattered by the gas[10].

Intergalactic Gas in Clusters of Galaxies

It is possible that the intergalactic medium is chiefly concentrated within clusters of galaxies, rather than being distributed smoothly. It has, for example, been suggested that the gas density within the Local Group (which is ~1 Mparsec in extent) may be as high as $\sim10^{-3}$ cm^{-3}. If this quantity of gas is indeed present, its temperature must be below 10^6 °K, otherwise it would emit a flux of soft X-rays in excess of what is observed. If other clusters of galaxies are similar to ours, however, they will, collectively, make a larger contribution to the X-ray background than the Local Group, because there would be several clusters with $z<1$ along any line of sight. We can therefore place an upper limit on the temperature of the gas within a typical cluster, which is slightly more stringent than in the smoothed-out case because the radiative losses per particle are proportional to the gas density. The limits on absorption would, however, be the same.

We consider separately those exceptionally large clusters, such as the ones in Virgo and Coma, which may contain large quantities of intergalactic gas, needed to satisfy the virial theorem[12]. Coma, for instance, would require $\sim3\times10^{48}$ g, and if this mass of gas were spread uniformly through a sphere of ~3.5 Mparsec diameter and had a temperature $\sim10^6$ °K, the 50 Å flux at our galaxy would be $\sim4\times10^{-26}$ erg cm^{-2} sec^{-1} (Hz)$^{-1}$

---

* If we adopted alternative (*a*) we could determine how the apparent discrepancy between the hydrogen column density and the X-ray opacity depends on direction by correlating the observed X-ray flux with the 21 cm intensity. One might thus obtain some insight into the cause of the discrepancy.

This approach contrasts with that used by Bowyer *et al.* who supposed that the X-ray opacity was proportional to the 21 cm intensity—which is equivalent to assuming that the process causing the anomalous 21 cm emission is equally efficient in all directions (the inferred discrepancy being a factor ~3).

The Coma cluster lies near the Galactic Pole, where, according to Bowyer *et al.*, the optical depth of the galaxy is $\lesssim 1/3$, and such a high flux would easily have been detected by these workers, despite the fact that their beam covered ~ 5 times the solid angle subtended by the cluster. Even if the higher conventional estimate for the opacity of the galaxy is correct, this flux would still be detectable. There is no evidence for enhanced emission from the Coma direction on the map published by Bowyer *et al.*, so we can presumably conclude that, if the "missing mass" in the Coma cluster is indeed in gaseous form, its temperature must be $\lesssim 5\times10^5$ °K. The expected X-ray intensity would be even greater if, as Woolf[13] has considered, the gas were concentrated towards the centre of the cluster or were distributed inhomogeneously. If the gas were present, but cool and neutral, its optical depth would be at least 60. The Coma cluster should then cast a shadow on the X-ray background* which would be observable by a detector with two or three times better angular resolution than that used by Bowyer *et al.* In this case, however, the cluster would be observed as a strong 21 cm emission feature and it is not[15]. If the temperature were a few times 10^5 °K, the hydrogen and the helium would be almost all ionized, but there would still be a "shadow" effect caused by heavy elements if they had more than 2 or 3 per cent of their "cosmical" abundance.

Quasars and Radio Galaxies

The only two extragalactic objects which are already known or suspected to emit detectable X-rays at shorter wavelengths are Virgo A and *3C* 273 (refs. 16 and 17). Although it is difficult to identify discrete X-ray sources without better angular resolution than that used by Bowyer *et al.*, a strong source might still be detectable above the background. One of the patches of strong soft X-ray emission on the map published by Bowyer *et al.* seems to coincide with the position of *3C* 273 ($l^{\rm II} = 290°$, $b^{\rm II} = +64°$). Although this may be a coincidence or (in view of the quoted errors) a chance fluctuation, it is worth considering the possibility that the excess flux from this patch of sky does indeed come from *3C* 273. Although this source is at a high galactic latitude, it lies in a direction where the 21 cm emission is rather high: the optical depth of the galaxy in this direction is ~ 1 according to the analysis of Bowyer *et al.* and ~ 3 on the conventional analysis. Taking Friedman and Byram's estimate of the intensity of *3C* 273 at 1–10 Å, we have calculated what spectrum the source would need to have in order to produce ~ 8 counts/sec in the detector used by Bowyer *et al.*, assuming that there is no absorption along the line of sight apart from that caused by the galaxy. We find that, if the spectrum is a power law, the slope has to be ~ -3 if the opacity has the conventionally assumed value, and ~ -1.5 if the lower estimate of Bowyer *et al.* for the galactic opacity is taken.

We do not, of course, know whether the spectrum of *3C* 273 is a power law (as would be likely if the X-rays are synchrotron or inverse Compton radiation) or an exponential thermal spectrum. It does not prima facie seem unreasonable, however, to suggest that the excess counts reported by Bowyer *et al.* in the direction of *3C* 273 are in fact emitted from this source. If this is indeed so, other interesting consequences follow. Koehler and Robinson[18] have reported 21 cm absorption in the radio spectrum of *3C* 273, which they attribute to neutral hydrogen in the Virgo cluster. If these observations are correct, they imply a H I column density of $\sim 1.3\times10^{19}$ T_s atoms cm^{-2}, where T_s is the spin temperature. The optical depth at 50 Å caused by this gas alone is therefore $\sim 4\times10^{-2}\,T_s$, if there are ~ 10 per cent of helium atoms in the cloud. Assuming that the X-ray opacity resulting from the cloud is $\lesssim 1$, we deduce directly that $T_s \lesssim 25°$ K. Such a low value for T_s is not unreasonable (and was inferred by Koehler[19] from other considerations), but this is a significant constraint on the properties of the H I cloud responsible for the 21 cm absorption.

Although Virgo A was found by Friedman and Byram[16] to be ~ 5 times stronger than *3C* 273 in the 1–10 Å wavelength range, there is no evidence on the map of Bowyer *et al.* for enhanced soft X-ray emission from its position. Koehler and Robinson found that the 21 cm absorption from this source was 25 per cent weaker than in *3C* 273. Koehler[19] pointed out, however, that there may be, within the galaxy *M*87, a large amount of gas with too high a spin temperature to contribute to the 21 cm absorption. This material would absorb X-rays, and an extra optical depth as low as ~ 2 would suffice to make Virgo A appear weaker than *3C* 273 at ~ 50 Å, even if its intrinsic spectrum were similar. Soft X-ray observations of extragalactic radio sources would thus not only extend our knowledge of their intrinsic spectra, but also place restrictions on the permitted properties of the diffuse intervening medium. It has recently been reported[17] that the X-ray spectrum of Virgo A is fairly flat at ~ 8 Å. This may indicate appreciable absorption even at ~ 8 Å, or an intrinsically flat spectrum. If either of these alternatives is correct, Virgo A would be too weak to have been detected at ~ 50 Å by Bowyer *et al.*

Accretion Wakes of Galaxies

Another possible source of soft X-rays is the accretion wake of the galaxy (and possibly of other galaxies). Ruderman and Spiegel[20] have discussed the flow pattern which would arise from the galaxy's motion, with supersonic velocity, through the general intra-cluster gas. They show that there would be a weak gravitationally enhanced conical shock behind the galaxy, and that, in a direction opposite to that of the galaxy's motion (that is, along the axis of the shock), there would be a "tail" of enhanced density, where the temperature could exceed 10^6 °K. They pointed out that this "tail" could be a source of soft X-rays. Its position in the sky can be estimated from an analysis of the velocities of galaxies in the Local Group[21], and it turns out to lie in the direction $l^{\rm II} \sim 340°$, $b^{\rm II} \sim +20°$. Bowyer *et al.* do in fact find intense X-ray emission from this direction, as well as enhanced emission from the whole surrounding area of sky. This coincidence is suggestive, although it may, of course, be merely due to chance.

An apparently unrelated coincidence is the following: the centre of the radio feature known as the North Polar Spur also lies in the same direction[22]. The Spur is widely believed to be the envelope of an old supernova remnant[23] (although there are difficulties associated with this interpretation[24]), so an alternative theory to explain the X-rays from $l^{\rm II} \sim 340°$, $b^{\rm II} \sim +20°$ would be to say that they come from the debris of the same explosion which gave rise to the Spur. It would then be pure chance that the centre of the Spur lies in the expected direction of the accretion wake of the galaxy. This last remark does, however, suggest a radically different interpretation, according to which the radio Spur either delineates the conical shock wave predicted by Ruderman and Spiegel[20] or results from the impact on the galactic disk of gas streaming in from the accretion wake. The fact that the centre of the Spur, the observed region of enhanced X-ray emission, and the expected accretion wake all lie in the same direction would not then be accidental. Furthermore, such a theory would account for the strong 21 cm emission from this direction and for the fact that the zone of avoidance seems to extend further from the galactic plane in this direction

---

* Gould and Sciama[14] suggested in 1964 that galaxies might cast shadows on the X-ray background. An angular resolution better than 1 degree would be needed to detect this effect. If it were possible to observe a shadow cast by a nearby galaxy, such as Andromeda, which has been mapped at 21 cm, one would be able to test whether amplification is causing a discrepancy between the 21 cm intensity and the X-ray opacity similar to that which may occur in our own galaxy. Of course such observations would also test whether the X-ray background is truly extragalactic.

High Velocity H I Clouds

Another source of diffuse X-rays near the galaxy might be associated with gas accreted by the galaxy from directions other than that of the accretion wake High velocity clouds of neutral hydrogen have been detected by 21 cm observations in the general direction $l^{II} = 70°–170°$, $b^{II} = +30°–+60°$ (ref 25) These clouds all seem to be falling into the galaxy with typical velocities of ~ -120 km sec^{-1}, and Oort[26] has suggested that they have an extragalactic origin If they have been captured by the galaxy's gravitational field, however, they should now have velocities of the order of 500 km sec^{-1} towards us, unless their speeds have been reduced in some way They may have been braked by cosmic ray pressure[27], but an alternative possibility is that the clouds have been braked by interaction with gas in the galactic halo[26] In the latter case, they would almost certainly impinge on the halo with supersonic velocities, so their motion would lead to the formation of shock waves, in which temperatures of a few million degrees would be attained[28] The gas behind these shocks would then emit soft X-rays The observed clouds lie in directions where the opacity of the galaxy is not too great, and calculations show that, if the gas density in the halo is adequate to produce the required deceleration, X-rays from the associated shocks may be detectable These X-rays may contribute to the flux observed by Bowyer *et al* away from the Galactic Pole, and future observations should enable us to set restrictions on the mass of the clouds, and perhaps to decide whether the braking is more likely to be caused by the halo gas or by cosmic rays The temperatures behind the shock waves are determined chiefly by the cloud velocities, and we would expect only very soft X-rays These would not be detectable except by the long wavelength observations which now for the first time seem feasible if the opacity of the galaxy has indeed been overestimated

Conclusions

Our discussion shows that important information on a variety of extragalactic phenomena could be obtainable from soft X-rays ($\sim$50–100 Å) if the column density of hydrogen in our galaxy were a few times less than is implied by a straightforward analysis of the 21 cm data Preliminary observational and theoretical considerations suggest that this is a very real possibility In view of the importance of the X-ray observations which would become possible, and also of the interstellar questions involved, we would urge that further observational and theoretical studies of this problem be carried out

We thank Dr C S Bowyer for communicating to us before publishing the results of his work with G B Field and J E Mack, and Miss S H Storer for advice on the problem of the column density of galactic neutral hydrogen

Directed Emission Model for Quasars

by
N A PORTER
University College,
Dublin,
Ireland

The difficulties of accounting for the powerful emission of energy from quasars can be resolved if the emission is assumed to be concentrated in one direction

If quasar red-shifts are assumed to be cosmological, considerable difficulties arise in reconciling short term variations with the magnetic and particle energies[1] If, on the other hand, the quasars are assumed to be local[2], it is very difficult to find a satisfactory explanation of the red-shift It would therefore seem that alternative and even somewhat artificial mechanisms may be worthy of consideration The possibility of a directed emission has been informally suggested, but its implications have not been considered in detail Coherent but isotropic emission has been suggested by Ginzburg and Ozernoy[3]

If the radiation is assumed to be isotropic, an energy emission of the order 10^{46} ergs per second is required in the continuum from 10^{7}–10^{15} Hz Mechanisms may exist, however, by means of which a beam of narrow angular spread could be produced We shall assume a number of sources of this type distributed with random orientation throughout the universe and having a characteristic beam width of the order of 0 1 sec of arc, 5×10^{-7} radians We will take account only of those which are directed towards us. The value of θ is chosen somewhat arbitrarily, the beamwidth could in fact be considerably larger than the observed angular diameter of the source In the mechanism which will be proposed, our choice is limited —chiefly by the very small proper motions which are observed

Accepting the specified value, however, the energy requirement for each source is now $E = 10^{46} \times \theta^{2}/4 = 10^{33}$ ergs/sec This is comparable only with the radiation from the Sun, so that the phenomenon becomes stellar in scale, rather than galactic The number of such sources must be very much larger than the number of quasars which have been observed About one hundred have been seen in a volume which is about one-tenth of the observable universe. Assuming that this is not a gross underestimate of the true density, the total number which is now required is about $10^{3} \times 4/\theta^{2} = 10^{16}$. If the phenomenon is intragalactic, 10^{6} sources are required for each galaxy, but the probability of observing one in our own or an adjacent galaxy is only about 10^{-7} because of the narrow beam width Quasar phenomena are therefore rather common occurrences in this model, they are stellar in magnitude, and may be individually quite short-lived

Experimentally, the lifetime of each quasar need only be about 100 years, and large variations in intensity are observed on time scales which are significantly shorter than this The energy requirement per quasar is therefore about 10^{42} ergs, and the power expended in each galaxy is about 3×10^{46} ergs per year This value is independent of the assumed beam width and is modest compared with the cosmic ray energy in our galaxy, which requires an estimated injection power of 10^{48} ergs/yr[4] The similarity of these orders of magnitude is itself striking

A mechanism for such emission presents difficulties which are not insuperable The injection of a stream of high energy particles into a region of uniform magnetic field could possibly produce enough power The expansion of a relativistic gas in the presence of magnetic fields will be along the field lines[5], and it has also been shown that non-spherical expansion of shock fronts from supernovae is possible[6] In these cases, the beam width and energy requirement would be much greater than in the example which is given here, and the number of sources would be correspondingly less

An alternative possibility could be a phenomenon which is analogous to the extensive air shower, developing over distances of galactic order of magnitude and initiated by a single high energy particle or coherent bunch of particles, as suggested by Hayakawa[7] In such a cascade, the medium of development is the isotropic microwave flux[8] Electron-photon development would be determined by the inverse Compton and photon-photon pair production cross-sections[9–11], and the nuclear development by the 3/2, 3/2 resonance cross-section[12] Loss of electrons by synchrotron radiation would be relatively rapid, and the principal directed continuum synchrotron emission would come rather from mesons, nucleons and anti-nucleons Multiple scattering would arise only from irregularities of the magnetic field, so that the disk of particles would remain thin in the line of sight, and lateral spread or curvature would be small The angular beam width would be of the order mc^{2}/E, where E is the typical particle energy, but at radio wavelengths phase coherent dipole emission from the whole disk might occur, modifying both the beam width and frequency spectrum In models of this type, the power requirement is considerably less than 10^{33} ergs/sec This is because, as in the case of Čerenkov radiation from an air shower, the radiation travels with the disk and is deposited in a time short compared with the transit time The effective time contraction factor could, in principle, be as large as $1/\theta^{2}$, but in practice would probably be determined by differences in path length, with a possible contribution from the differential recessional velocity over the path traversed If the phenomenon is confined to galaxies, the contraction factor would be of the order of 1,000 for an apparent lifetime of 100 years For extragalactic emission, it could be as large as 10^{8}, a limit being set by the Hubble constant Large fluctuations in power[13] would be caused by transit through field irregularities, but these would also be contracted in time scale Power output requirements for the continuum are about 10^{23} W for a galactic effect, or for an extragalactic effect could be as low as 10^{18} W

For protons, lower limits on particle energies are set by the requirement that the deviation of the shower paths in magnetic fields must be less than 0 1 sec of arc over the total path length observed With $B = 10^{-6}$ gauss, particle energies of about 10^{25} electron-volts are required, but because synchrotron losses are large, at these energies, even for protons, rapid degradation would occur, both by nucleon-photon collisions[12] and by synchrotron losses, to effective energies in the region 10^{16} electron-volts The critical frequency for protons would be in the soft X-ray region The total energy of the phenomenon must, of course, be about 10^{42} ergs, and a very large number of particles—about 10^{26}—must be radiating at any given time Because of the coherent dipole character of the radiation at long wavelengths, some apparent structure would be expected, but this would arise from the overlapping of coherent wavefronts rather than from a real linear separation

To satisfy observational requirements, line spectra must be excited coherently as the flux which is observed in such lines as Hβ is of the order 10^{42} erg/sec, assuming isotropic emission The inherent diffraction width for coherent radiators, spread over a distance T, is $\theta = (\lambda/T)^{\frac{1}{2}}$, so that, at optical frequencies, phase coherence must be preserved over distances of about 10^{8} cm The short wave radiation of the continuum traversing a galaxy would excite interstellar gas atoms By analogy with the laser, these would then emit stimulated emission as a result of being triggered by the appropriate wavelength of the continuum The continuum consists of wave trains which, although not mutually coherent, would be of sufficient length to constrain the line emission into an angular distribution similar to that of the continuum The power requirement is about 10^{22} W, and emission would be observed from a cylindrical volume of about 10^{63} cm^{3}, which in a normal galaxy contains enough atoms to give the required emission. Because of the time contraction of the continuum, the excitation power is sufficient If the shower disk traverses the galaxy, some excitation would be caused by the particles also, but because the diameter of the disk would only be about 10^{6} cm, the number of atoms which would be affected would be relatively small Line broadening would arise from differential red-shift across the emitting galaxy, and the overall red-shift would be that corresponding to the distance of the galaxy

Not all the quasar lines which have been observed[14] have been found in interstellar spectra, but because the conditions of excitation are unusual, this difficulty may not be serious Rapid changes in line intensities, again time contracted, would be expected, as the continuum traverses interstellar clouds The presence of line emission does not necessarily imply that the continuum is produced in galaxies, for there is a significant possibility that radiation originating at cosmological distances will intersect a galaxy on its path to the observer

The polarization which would be expected in coherent phenomena, or in incoherent radiation from particles traversing the same magnetic field, would remain in this model, but would change rapidly Complete polarization would not be expected at any time as the wave trains from different regions will overlap

There are, of course, very serious difficulties in explaining the acceleration of cosmic ray particles, even to the energies of about 10^{20} electron-volts which have been observed It would probably be necessary to invoke particles such as the magnetic monopole[15], with subsequent production of monopole pairs, to obtain a sufficiently high energy

The possible contributions of monopoles to the primary cosmic radiation have been pointed out previously[16], and it would seem that there is now some tentative evidence for their existence[17] Fermi acceleration mechanisms and production cross-sections for cosmic ray monopoles have been considered by Goto[18] and Alvarez[19]

In the present case, we postulate a cascade proceeding in a region of reasonably linear magnetic field The principal production cross-section for monopole pairs for incident monopoles of 10^{18}–10^{20} electron-volts, in galactic or halo regions, is probably with the microwave flux If ν is the average production multiplicity, and l the distance traversed in interaction lengths, the number of monopoles $N = \left(\frac{\nu}{2}\right)^{l}$, because only one sign of pole will contribute to the cascade Opposite poles will be decelerated, come to rest and initiate individual cascades of their own

The rate of extraction of energy from the magnetic field is $NgBD$ ergs per yr, where N is the number of monopoles, g the pole strength (assumed $3\ 3 \times 10^{-8}$ EMU), B the field and D one light year In a field of 5×10^{-6} gauss, 10^{32} monopoles are required to extract 10^{23} Watts If we assume $\nu = 20$, and a cross-section 10^{-25} cm^2, for interaction with the microwave field, the required value of N will be reached in 3×10^4 yr These assumed values are, of course, arbitrary, but not entirely implausible (Because $g^2/\hbar c = 34$, multiple production is expected, even in electromagnetic interactions) Effects of radiation damping and magnetic space charge are complex, and could slow down significantly the development of the process Individual particle energies greater than 10^{20} electron-volts are not required in this model, for collimation would be preserved by the monopole component, and the electromagnetic radiation would be emitted by a rapidly degraded secondary electron component The diameter of the disk in this model is 10^{16} to 10^{17} cm, and the magnetic field energy swept out is sufficient to provide the observed power As in the proton cascade, time contraction occurs and structural changes may be seen at a speed apparently greater than the velocity of light

If we wish to explain the normal cosmic radiation within our galaxy as the degraded residue of this process, the total number of monopoles required to extract 10^{48} ergs/yr from the magnetic field is about 10^{43} This corresponds to an average density of 10^{-24} monopoles/cm^3, which is compatible with the experimental upper limits[17,20,21]

Pharmacological Basis for the Tobacco Smoking Habit

by

A K ARMITAGE

G H. HALL

CATHLEEN F MORRISON

Department of Pharmacology,
Tobacco Research Council Laboratories,
Harrogate

Small amounts of nicotine injected intravenously usually increased the lever pressing activity of rats and caused a change in the EEG of cats indicative of cortical activation These results in experimental animals are consistent with the subjective impression of some smokers that inhalation of tobacco smoke causes them to be more alert and efficient

ALTHOUGH the pharmacology of nicotine has been studied in considerable detail since Langley[1] first showed that nicotine stimulated and then paralysed ganglion cells, many of the published data are of little or no relevance to the pharmacology of tobacco smoking[2] It is generally agreed that nicotine plays an important part in the tobacco smoking habit, but in spite of much discussion and research the precise action of nicotine remains unknown[3] Johnston[4], however, showed clearly that the cravings of habitual smokers could be successfully appeased by nicotine injections instead of smoking We believe that our findings in recent experiments with nicotine on cats and rats provide an objective pharmacological explanation for the tobacco smoking habit.

Nicotine Absorption during Cigarette Smoking

The nicotine content of a puff of tobacco smoke is dependent on the way in which a cigarette is smoked. As a result of a survey carried out in the United Kingdom on behalf of the Tobacco Research Council, it has been found that most smokers take between one and two puffs

Table 1 NICOTINE CONTENT OF THE MAINSTREAM SMOKE OF STANDARD CIGARETTES

Puff volume (ml)	Average time to smoke (min)	Average nicotine in the smoke per cigarette (mg)	Average nicotine in the smoke per puff (mg)
35	9	2.5	0.25
30	10.4	2.3	0.20
25	10.2	1.96	0.17
20	11	1.64	0.14

The cigarettes, made from a blend of several different tobaccos currently used in the manufacture of British cigarettes, were smoked on an apparatus described before by Armitage[5] to a butt length of 20 mm with a puff duration of 2 sec and a puff frequency of 1/min.

each minute, a puff lasting about 2 sec with an average volume of about 25 ml. We used a pump that would smoke cigarettes in this way and which was capable of introducing any selected puff volume into the lungs of an anaesthetized cat[5]. Table 1 shows how the nicotine content of a puff of cigarette smoke varied with the puff volume when the puff duration and frequency were kept constant. The larger the volume of the puff the quicker the cigarette was smoked, with more nicotine appearing in the smoke each puff. With a 35 ml puff volume there was nearly twice as much nicotine in each puff compared with a puff volume of 20 ml. In this way, a smoker takes into his mouth a total of about 1–2 mg of nicotine during a smoking time of approximately 10 min. A biological experiment is necessary to ascertain how much nicotine is absorbed and how quickly it is absorbed. We therefore compared the rise in blood pressure caused by a puff of tobacco smoke administered to the lungs of an anaesthetized cat with the rise in blood pressure caused by nicotine injected intravenously. Fig. 1 shows the effects of 40, 80 and 120 μg of nicotine injected into a femoral vein on the femoral arterial blood pressure of a cat anaesthetized with chloralose, compared with the rise in blood pressure caused by the third puff of a cigarette (25 ml puff volume, lasting 2 sec). The time course of the rise in blood pressure caused by the puff of tobacco smoke was almost identical with that resulting from an intravenous injection of nicotine. This shows that inhalation of tobacco smoke in man is an extremely efficient way of administering nicotine. The amount of nicotine in the "man sized" puff of tobacco smoke in this and other experiments caused a rise in blood pressure similar to 120 μg of nicotine base injected intravenously, that is, a dose of about 30 μg/kg. If the average man weighs 70 kg, every time he inhales a puff of tobacco smoke he can be expected to receive a dose of nicotine roughly equivalent to between 1 and 2 μg/kg administered intravenously. It is worth noting that someone smoking a cigarette has literally finger tip control of how much nicotine he takes into his mouth; by reducing the puff volume or inhaling less frequently he absorbs less nicotine.

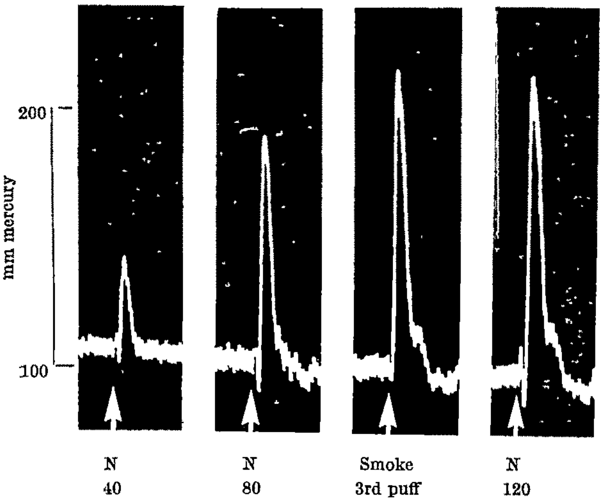

Fig. 1. Record of mean femoral blood pressure of a cat weighing 4 kg, artificially ventilated, under chloralose anaesthesia. In the first, second and fourth panels, nicotine (N) was injected into a femoral vein, the dose being 40 μg, 80 μg and 120 μg, respectively. In the third panel is shown the rise in blood pressure caused by a 25 ml puff of tobacco smoke administered to the lungs by means of a pump.

It seems likely that some people smoke in order to dose themselves with nicotine, and our particular concern has been to find out what effect these small amounts of nicotine have on a smoker. Tobacco smokers have frequently stated that they are either "tranquillized" or "stimulated" as a result of smoking a cigarette, and although this evidence is purely subjective it cannot be dismissed. To investigate this experimentally it was necessary to administer nicotine to a conscious unrestrained animal in a series of small intravenous doses and to observe its effect on some measurable aspects of behaviour. The behaviour of thirsty rats which have been trained to press a lever to obtain water is particularly sensitive to the effects of drugs acting on the brain, and we therefore decided to examine the effects of nicotine on this type of conditioned behaviour which was first described by Skinner[6]. A rat, once trained, gives a consistent day to day performance and thus serves as its own control.

Effects of Nicotine on Behaviour

Small subcutaneous doses of nicotine have been shown to increase the rate at which thirsty rats will press a lever for water rewards[7,8]. This effect is most clearly seen when rewards are made available at varying intervals, under which condition the rats press the lever at a steady rate. In a number of similar experiments, we gave nicotine intravenously as a series of small injections to a conscious unrestrained rat while it was pressing the lever in a Skinner box. For this purpose a cannula made out of polythene tubing was placed in the jugular vein during an aseptic operation and was exteriorized from the back of the neck where it remained undisturbed by the rat[9]. Fig. 2 illustrates the effect of intravenous nicotine on the lever pressing behaviour of a rat which had been trained to press a lever to get water. The lever pressing records of 3 consecutive days are shown and these were charted automatically by a pen recorder which moved upwards each time the lever was pressed. The steeper the slope of the record the faster was the rate of lever pressing. Records *a* and *c* show the lever pressing performance of the rat on 2 control days when for the first 20 min of the 90 min session the rat was given saline intravenously in a volume of 0.005 ml every 30 sec. The rat pressed the lever 558 and 714 times on these 2 days. On day 2 (record *b*) the rat was given 0.5 μg of nicotine every 30 sec for 20 min, that is, forty doses of about 2 μg/kg. Under the influence of nicotine the rat pressed the lever 1,133 times during the 90 min session, an increase of 78 per cent over its average score for the 2 control days. This dose of nicotine (2 μg/kg every 30 sec) increased the lever pressing activity of most of the rats (eleven out of eighteen, mean increase of 62 per cent), had no effect on four rats and decreased the activity of the remaining three.

Not only do the behavioural effects of nicotine vary from animal to animal but they are also dependent on the rate at which the drug is injected. Experiments have been made in which the same total amount of nicotine (80 μg/kg) was administered at different rates over a period of 20 min. In the same rat, 4 μg nicotine/kg injected every 60 sec usually caused less stimulation than 2 μg/kg every 30 sec. In a few experiments, the effects of the two regimes were the same. When the nicotine injections were given more frequently (1 μg/kg every 15 sec) the lever pressing activity of some rats was increased but the behaviour of others was depressed although they had been stimulated when the nicotine was injected more slowly.

It seems probable that the increased activity of these animals under the influence of nicotine is a manifestation of some kind of central stimulation. The effect is similar to that caused by low subcutaneous doses of nicotine, and Bovet *et al.* have shown that these doses can improve the learning ability of rats and mice in several different tests[10,11].

Effects of Nicotine on the Electroencephalogram

MacIntosh and Oborin[12] first showed that acetylcholine was spontaneously released from the surface of the brain. They collected the acetylcholine in a small cup placed on the exposed cortex and measured the amount that accumulated in a given time. This important finding initiated much research into the role of acetylcholine in the central nervous system, as a result of which there is now substantial evidence that one of its functions is that of a transmitter substance for the propagation of nerve impulses in the cerebral cortex. It has also been shown[13] that the rate of release of acetylcholine from the cerebral cortex of the cat can be related to its state of activation—in the awake animal the output of acetylcholine increases and in the sleeping animal it decreases. Simultaneous recording of the brain electrical activity confirms a positive relationship between the rate of release of acetylcholine and states of consciousness.

In an attempt to ascertain whether the increased activity of rats under the influence of nicotine was a manifestation of stimulation, we have made a series of experiments[14] on anaesthetized cats in which acetylcholine was recovered from the cortex, using the technique described by Mitchell[15], with simultaneous recordings of the electroencephalogram.

Fig. 3 shows the result of a typical experiment, on the left the acetylcholine release from the left parietal cortex in ng/20 min/cm² and on the right records of the electroencephalogram from the left and right parietal cortex (LPC and RPC) at various times during the experiment. In this experiment, the resting output of acetylcholine was in the range 2.5–4 ng/20 min/cm² and throughout this period the typical electroencephalogram is shown in *a–d*. The pattern recorded from both hemispheres resembled light sleep and consisted of slow waves punctuated by bursts of spindle activity. At the black bar, nicotine was given intravenously in a dose of 2 µg/kg every 30 sec for 20 min so that altogether forty injections of this amount were given. Shortly after the start of the 20 min injection period the electroencephalogram showed a dramatic change indicating cortical activation. The spindle bursts became less frequent in occurrence and the accompanying slow wave activity was reduced in amplitude. This electrocortical desynchronization was accompanied by an increased release of acetylcholine into the cortical cup which persisted until the end of the experiment. It should be noted, however, that the electroencephalogram had assumed its original pattern while the acetylcholine concentrations were still elevated. When twenty injections of nicotine (4 µg/kg) were given every minute for 20 min, that is, a larger dose given less frequently but the same total dose as in Fig. 3, similar effects were usually observed. In one experiment, however, there was a decrease in the acetylcholine output from about 5 ng/20 min/cm² before the nicotine was given to about 2 or 3 ng/20 min/cm² after the nicotine, and the output of acetylcholine remained at this level for more than 2 h. The electroencephalogram changed from the typical pattern of spindle bursts and slow waves before nicotine to one in which spindle burst activity was reduced and the amplitude of the accompanying slow waves was increased. These changes were indicative of a reduction in cortical activity. In ten experiments in which nicotine (2 µg/kg/30 sec) was given as a series of small intravenous injections, there was an increase in cortical acetylcholine output in seven of these experiments and there was always a positive correlation with the change in the activity of the electroencephalogram. In six experiments in which a larger dose of nicotine was given less frequently (4 µg/kg/min), cortical activation with an increased output of acetylcholine occurred in three experiments, and in two experiments there was a decrease in cortical acetylcholine output accompanied by depression of cortical activity. One of us (G. H. H.) has also shown that nicotine (2 µg/kg/30 sec) causes cortical activation and behavioural arousal in the unanaesthetized *encéphale isolé* preparation and in the conscious unrestrained cat.

It therefore seems that nicotine can have two effects; it can cause either an increase or a decrease in the amount of acetylcholine released from the parietal cortex and can cause changes in the electroencephalogram consistent either with increased or decreased cortical activity. It seems likely that the effect varies from cat to cat, and even with small changes in the dose of nicotine and the rate of injection.

There are good reasons for believing that forty intravenous injections of 2 µg/kg of nicotine given every

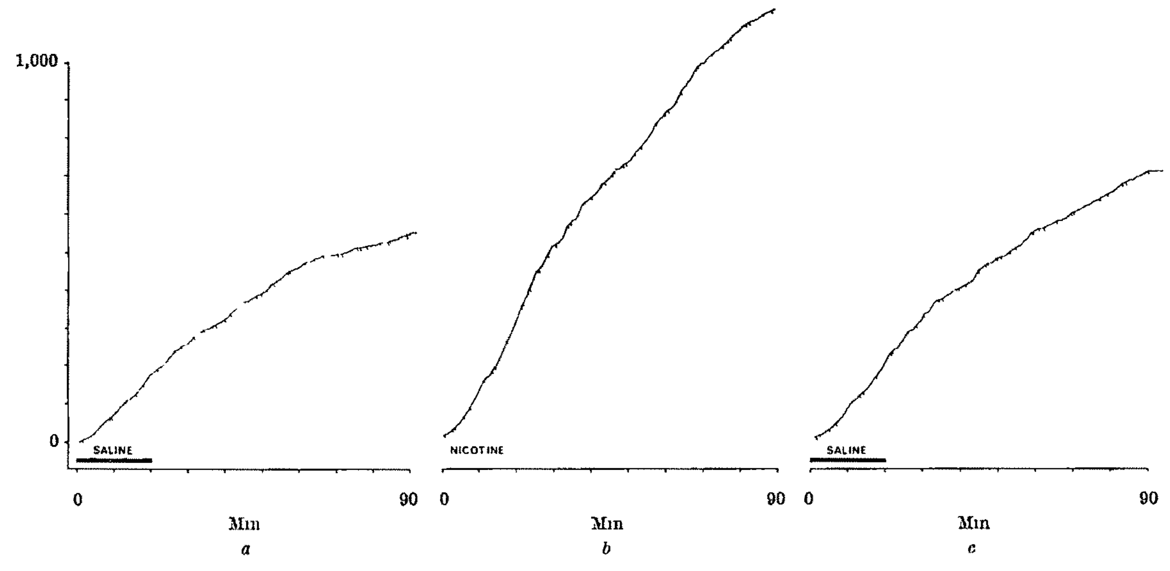

Fig. 2. The effect of intravenous nicotine (2 µg/kg every 30 sec for 20 min) on the lever pressing performance of an intravenously cannulated rat. Ordinate is number of times the lever was pressed, and abscissa is time in minutes. The small blips on the records indicate the occasions on which water was presented to the rat.

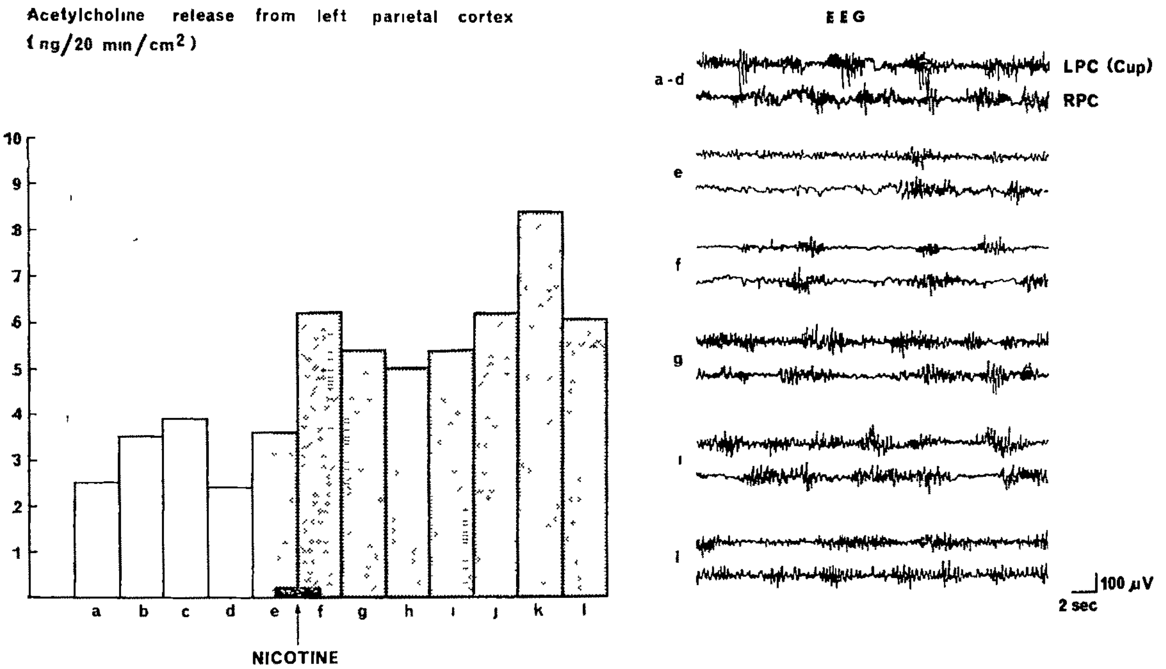

Fig. 3. Records of electrocortical activity and acetylcholine release from the left parietal cortex of a cat weighing 3.5 kg under 'Dial' anaesthesia. At the black bar, nicotine was given intravenously in a dose of 2 µg/kg every 30 sec for 20 min. Note the change in electrocortical activity (*e* and *f*) caused by the nicotine and the more prolonged changes in the amount of acetylcholine released

30 sec for 20 min is roughly the nicotine intake of a smoker, smoking two cigarettes and inhaling deeply. An increase in alertness on smoking a cigarette, that is to say an increase in cortical activity similar to that caused by intravenous nicotine in the cat, might be the explanation of the subjective impression that concentration and efficiency of the smoker are improved. We suggest that such effects of nicotine in man probably depend critically on the dose and rate of self-administration and also on whether he is excited or depressed. In this restricted sense the nicotine probably merely brings about a normal physiological response which can occur without intervention of a drug.

We are aware of the fact that the effects of nicotine that we and others (notably Domino[16] and Bovet[17]) have shown to occur in animals have not yet been conclusively demonstrated in man, and some carefully controlled experiments in human pharmacology are clearly needed.

Formation and Chemical Pumping of OH Molecules

by
P. M. SOLOMON
Department of Astronomy,
Columbia University,
New York

It has been suggested that maser amplification may be the cause of intense OH lines observed in some small sources. An efficient two body pre-association of hydrogen and oxygen may lead to the formation of OH and the population inversion needed for maser amplification.

RECENTLY there have been extensive astronomical observations of four radio lines at 1612, 1665, 1667 and 1720 MHz, arising from transitions between levels of the λ doublet in the ground state of OH. The radiation in the lines is extremely strong and seems to come from small sources with brightness temperatures as high as 10^{12} °K. The line intensity ratios deviate strongly from those expected in conditions of thermodynamic equilibrium and the line width is extremely narrow. In addition, the lines exhibit varying degrees of circular and linear polarization. In order to account for the extraordinary nature of these observations, the existence of maser amplification has been suggested Recent reviews by Barrett[1] and Robinson and McGee[2] discuss the detailed observational evidence leading to this conclusion

In addition to the existence of a mechanism which leads to population inversion (and therefore a maser), there must also be a process producing the OH in appropriate astrophysical conditions In this article I suggest that the process responsible for both formation and population inversion is the relatively efficient two body pre-association of oxygen and hydrogen atoms taking place at moderately high temperatures of the order of 1,000° to 2,000° K The processes of destruction of OH must also be taken into account, for it is precisely the nature of the destruction processes which leads to the conclusion that chemical pumping as opposed to optical pumping must be responsible for the population inversion

The pre-association reaction leading to the formation is

$$\mathrm{H}(^2S) + \mathrm{O}(^3P) \rightarrow \mathrm{OH}(^2\Sigma^-) \rightarrow \mathrm{OH}(^2\Sigma^+_{v=2}) \rightarrow \mathrm{OH}(^2\Pi) + h\nu \qquad (1)$$

The potential energy diagram of the molecular states is shown in Fig 1

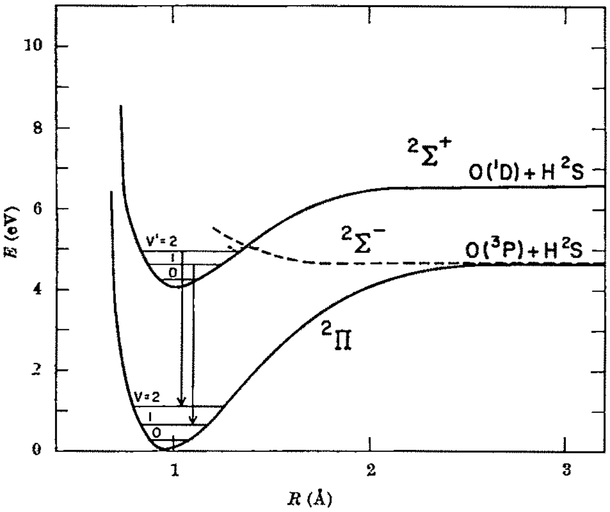

Fig 1 Potential energy curves for OH, showing the formation of ground state molecules by inverse pre-dissociation

Evidence for this reaction was first obtained by Charton and Gaydon[3], when they noticed that in low pressure flames an extremely high emission intensity originated from the $v' = 2$ level of the OH band $^2\Sigma^+ \rightarrow {}^2\Pi$ Many characteristics of an inverse pre-dissociation (pre-association), such as a strengthening of lines originating from f_1 levels and the existence of the effect only at low pressure, led to the conclusion that reaction (1) was responsible This was confirmed in an experiment by Kaskan[4], who found that the intensity of the bands is proportional to the square of the free atom density, and thus proved that a two body reaction was responsible The rate coefficient and temperature dependence measured by Kaskan is $K_1 = 3 \times 10^{-15} \exp(-3{,}700/T)$ cm³ sec⁻¹ where the rate of production of molecules is given by $N_{\mathrm{OH}} = N_{\mathrm{O}}N_{\mathrm{H}}K_1$ It should be noted that while this is slow in comparison to chemical reactions it is two to three orders of magnitude faster than other known radiative association processes[5]

The two basic types of destruction processes are chemical exchange and photodissociation Because of the large cosmic abundance of hydrogen the major chemical exchange reaction will be

$$\mathrm{H} + \mathrm{OH} \rightarrow \mathrm{H}_2 + \mathrm{O} \qquad (2)$$

with a rate coefficient[6] $K_2 = 1\ 0 \times 10^{-11} \exp(-3{,}700/T)$ Formation and destruction of OH by reactions (1) and (2) have the effect of cycling the oxygen atoms through OH and then making them available again for the production of OH Thus at any time the ratio [OH] [H] is independent of the density, but the rate of production of OH per cm³ is proportional to the square of the density There is an uncertainty in the activation energies involved of several hundred degrees, but to within experimental error the temperature dependence is the same In conditions where (2) is the dominant destruction mechanism, the abundance of OH is $[\mathrm{OH}] = 3 \times 10^{-4}\,[\mathrm{O}] = 3 \times 10^{-7}\,[\mathrm{H}]$

Recently Hughes[7] made a suggestion, based on experiments by Spindler *et al* [8], that OH may be formed through pre-association in the $v' = 0$ level The rate coefficient for this process is (see ref 8) 3×10^{-21} cm³ sec⁻¹ This is five orders of magnitude smaller than the pre-association through $v' = 2$ at a temperature of 2,000° K A consistent interpretation of these data is that the level crossing involved in these reactions occurs at an energy corresponding to $v' = 2$, and the much lower rate at $v' = 0$ is a result of the inefficiency of tunnelling through the potential barrier In the analysis of the production of OH in interstellar conditions, Hughes[7] completely neglected any destruction mechanism and thereby concluded erroneously that the OH abundance could build up indefinitely In fact, the production of OH with a rate coefficient of 3×10^{-21} cm³ sec⁻¹ is negligible because the rate of either collisional destruction or photodissociation will be ten orders of magnitude greater

The rate of photodissociation of OH, and the pumping mechanism responsible for the inversion, are closely related questions Optical pumping of OH through absorption and re-emission (at $\lambda = 3080$ Å) in the $X^2\Pi \rightarrow A^2\Sigma^+$ bands has been suggested by Perkins *et al* [9] and Litvak *et al* [10] The total f value for this band, however, is only 8×10^{-4} (ref 11) Considerations of the photodissociation rate in H II and H I regions, near hot stars, show that the molecule will be destroyed more rapidly than it will be pumped If the OH exists in an H II region, it will be exposed to radiation at $\lambda < 912$ Å which is capable of photoionizing it with a total f value of 1 The rate of destruction of the molecule by photoionization in the radiation field of a hot star will therefore exceed the pumping rate by three or four orders of magnitude The lifetime of a molecule after entering the H II region will be only 1 year, it is therefore impossible to have OH molecules in an H II region unless they are shielded from the radiation in a cooler cloud, in which case they will not actually be in an H II region but surrounded by it

The question of photodissociation in an H I region, where there is no radiation at $\lambda < 912$ Å ($E > 13\ 6$ eV), is more complicated because the potential energy curves for the unbound states can only be approximated Fig 2 shows the potential energy curves for the two bound states ($X^2\Pi_{3/2}$ and $A^2\Sigma^+$), the unbound $^2\Sigma^-$ and the $B^2\Sigma^+$ state which has a very low binding energy The curves for the X and A states and the bound portion of B ($r > 1\ 4$ Å) are empirical curves based on the RKR method from Fallon *et al* [12] The unbound $^2\Sigma^-$ curve has been estimated on the basis of a crossing of the A state at $v = 2$, and the portion of B with $r < 1\ 4$ Å has been obtained by extrapolation The shaded area represents the range of internuclear separation in which transitions from the ground state must take place according to the Franck–Condon principle All transitions to repulsive curves in this region will lead to photodissociation (All possible cases for $E > 13\ 6$ eV have been neglected because there are no photons of this energy in H I regions) It can be seen from the diagram that transitions to both $B^2\Sigma^+$ and $^2\Sigma^-$ states occur at about 11 5 eV and 7 eV, respectively In the case of the $^2\Sigma^-$ state, if the identification with the level crossing is correct, there can be no doubt that photodissociation will take place at energies less than 13 6 eV The f value for these transitions is unknown, but the transitions $^2\Pi \rightarrow {}^2\Sigma^+$ and $^2\Pi \rightarrow {}^2\Sigma^-$ are both permitted sub Rydberg transitions and should therefore have similar strength

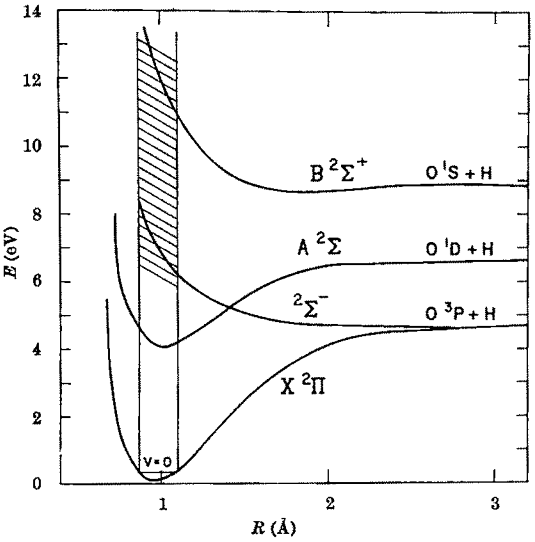

Fig 2 Potential energy curves of four OH electronic states demonstrating photodissociation transitions from the ground state to $^2\Sigma^-$ and $B^2\Sigma^+$

All the strong OH emission regions are observed near hot stars on the borders of H II regions, in these conditions the radiation field will be characterized by a temperature of approximately 30,000° K The rate of photodissociation R, for a molecule in a radiation field of this temperature, with a dilution factor $W = 10^{-16}$ has been calculated for the processes

$$\mathrm{OH}(^2\Pi) + h\nu(7\ \mathrm{eV}) \rightarrow \mathrm{OH}(^2\Sigma^-) \rightarrow \mathrm{O}(^3P) + \mathrm{H}(^2S) \qquad (3)$$

and

$$\mathrm{OH}(^2\Pi) + h\nu(11\ 5\ \mathrm{eV}) \rightarrow \mathrm{OH}(B^2\Sigma^+) \rightarrow \mathrm{O}(^1P) + \mathrm{H}(^2S) \qquad (4)$$

assuming that the f value for each transition is 8×10^{-4}. The total rate of photodissociation $R = R_3\,(1\ 2 \times 10^{-11}) + R_4\,(0\ 6 \times 10^{-11}) = 1\ 8 \times 10^{-11}$ sec^{-1} is greater than the maximum pumping rate $P = 0\ 55 \times 10^{-11}$ sec^{-1} (at $\lambda =$ 3080 Å) calculated in the above conditions for a strong inverting transition, with a strength equal to half of the total electronic f value Actually the dissociating transition is at a higher frequency than the absorption lines responsible for the pumping, and the dissociating f values and rates may even be greater than estimated

The rate for collisional destruction, per OH molecule by chemical exchange (reaction (2)) is $N_{\mathrm{H}} \times 10^{-11}$ exp $(-3{,}700/T)$ This exceeds the ultraviolet pumping and photodissociation rates when N_{H} exp $(-3{,}700/T) > 1\ 8$ For temperatures of 1,000 and 2,000° K, collisions will dominate at number densities $N_{\mathrm{H}} > 70$ and $N_{\mathrm{H}} > 11$, respectively When the rate of chemical reactions exceeds that of photo-reactions the pumping mechanism must also be chemical

An alternative to pumping by ultraviolet radiation is the selective formation of OH in the upper state of the Λ doublet. The ultraviolet pumping mechanism which has been proposed[10,11] works by selective absorption into levels of the $A^2\Sigma^+$ state Because this is the state that the molecule is forming in, a population inversion could result directly from preferential formation in those levels (of $A^2\Sigma^+$) which decay into the upper level of the Λ doublet As an example of the possibilities involved it can be shown by consideration of the selection rules involved that formation into the $J = \frac{1}{2}$, $K = 1$ negative state of $A^2\Sigma^+$ leads to a very strong population inversion with all cascades direct to $^2\Pi_{3/2}$ going into the upper level of the Λ doublet In the ultraviolet pumping scheme[10], absorption in this line leads to very strong anti-inversion because the upper level is depopulated A more complete analysis and theoretical understanding of the formation process are necessary in order to predict the population inversion as a function of physical conditions, but the existence of a mechanism leading to population inversion by selective formation makes it possible to achieve high pumping rates without requiring that all strong OH emission sources be extremely close to unobservable $O5$ stars

In the case of the extremely strong sources such as $W3$, the pumping rate required to explain the observations is approximately 0 01–1 0 cm^{-3} sec^{-1} As has been pointed out by Shklovsky[13], this could not be realized by ultraviolet pumping even if the star were in the centre of the concentration If it is assumed that each formation leads to 0 5 to 1 0 radio photons, then the formation mechanism suggested here requires an average number density of $N_{\mathrm{H}} = 10^8$ to 10^9 cm^{-3} at a temperature of approximately 1,000°–2,000° K One of the predictions that can be made from this requirement is that OH sources should be strong emitters in the infrared. Raimond[14] has pointed out that the OH emission source in Orion is coincident with a strong infrared source

The operation of the OH formation mechanism suggested here implies that the presence of OH is a necessary consequence of high temperature and density in interstellar matter resulting directly from the nature of atomic processes in these conditions The astronomical object which meets these physical conditions most readily is a protostar The highly complex OH emission sources are far more likely to be a result of the poorly understood yet universal process of stellar formation, rather than, as has been suggested by Barrett[1], the completely unknown and rare, later stages of evolution which may be called super-intelligent life

I thank Professor G Field and Dr P Thaddeus for useful discussions This work was supported in part by the US National Aeronautics and Space Administration

Response of Bacterial Spores and *Micrococcus radiodurans* to Ultraviolet Irradiation at Low Temperatures

by
M. J. ASHWOOD-SMITH
J. COPELAND
J. WILCOCKSON

Harwell, Didcot,
Berkshire

At low temperatures, bacterial spores and *Micrococcus radiodurans* show paradoxical changes in sensitivity to the lethal effects of ultraviolet irradiation.

MANY micro-organisms are supersensitive to the lethal effects of exposure to ultraviolet light when irradiated at low temperatures in the frozen state[1]. The possible nature of this supersensitivity has been discussed[2] with the conclusion that damage to the DNA not associated with the thymine dimer was probably involved. The lesion induced by ultraviolet light at low temperatures is not amenable to repair by the normal repair processes present in most bacteria, nor is it photoactivable (ref. 3 and unpublished results of J. Wilcockson). The induction of mutations in *Escherichia coli* when irradiated with ultraviolet light in the frozen state is increased at low temperatures in a manner similar to the lethal response in that there is an increasing number of induced mutations with decreasing irradiation temperature[4].

Ashwood-Smith and Bridges[1] reported that the spores of *Bacillus subtilis* were supersensitive to ultraviolet induced killing at −79° C. Donnellan (personal communication), however, had noted that the spores of *Bacillus megaterium* were much more resistant to ultraviolet radiation at −196° C than at normal room temperature. We confirmed this observation with the spores of two strains of *B. megaterium* irradiated at liquid nitrogen temperatures, but also demonstrated that these same spores when irradiated at −79° C were nearly three times more sensitive than at 25° C. These results led us to examine, in considerably more detail, the effect of temperature in the solid state on the ultraviolet sensitivity of the spores of *B. subtilis* and the vegetative cells of the extremely radio-resistant bacterium, *Micrococcus radiodurans*. The response of *E. coli* in similar circumstances[1,2], although already well known, has been included in the present results for comparative purposes.

The irradiation procedures used in this study were essentially similar to those reported earlier[4]. The ultraviolet source was a low pressure mercury lamp about 98 per cent of the output of which was at 2537 Å. The ultraviolet flux at a distance of 30 cm from the source was 65 ergs mm^{-2} sec^{-1}. All the experiments were carried out in a darkened room as a precaution against photoreactivation. The spores of *B. subtilis* were prepared on Schaeffer agar plates, collected and freed of vegetative cells by treatment with sodium lauryl sulphate and lysozyme according to the method of Yoshikawa[5]. These spores were stored at 4° C in distilled water until used. *E. coli B/r WP2* (tryptophan-requiring) was grown in nutrient broth (Oxoid) at 37° C until the latter part of the logarithmic growth phase had been reached. The cells were collected and suspended in M/15 phosphate buffer (*p*H 6·8) for irradiation. *Micrococcus radiodurans* (National Collection of Industrial Bacteria, Aberdeen, Scotland, NCIB code number 9279) was grown in nutrient broth to which had been added 0·5 per cent glucose, and these cells were also collected and suspended in phosphate buffer when in the latter phase of logarithmic growth. Suspensions of cells or spores were cooled to −196° C as previously described[1] and then warmed to the irradiation temperature. Immediately after irradiation the frozen suspensions were thawed quickly by immersing the irradiation vessel in water at 37° C and colony counts for viable cells were made on nutrient agar plates for all three micro-organisms; 0·5 per cent glucose was added to the plates used for estimating colonies of *M. radiodurans*. Corrections were made for cell death associated with the freezing and thawing procedures. About 70–90 per cent of the cells of *E. coli* survived the freeze–thaw cycle. Survival of *M. radiodurans* and the spores of *B. subtilis* was nearly 100 per cent. Each experiment was repeated three times and complete survival curves were constructed. The D_{90} values were extracted from the curves and the average values in ergs mm^{-2} were plotted on a logarithmic axis against the irradiation temperature for the three bacterial types. Presentation of the results in this manner (Fig. 1) permits easy comparison of the differing sensitivities to ultraviolet radiation and the effect of temperature on these sensitivities.

The survival of *E. coli* suspended in phosphate buffer and plotted as a function of the irradiation temperature is similar to that already published[1] in that there is a progressive increase in sensitivity with decreasing temperature down to about −80° C. At lower temperatures the sensitivity, although still considerably greater than at 25° C, becomes progressively but rather slowly less marked. Similar observations have been made by Smith and O'Leary[3]. The spores of *B. subtilis* are nearly four times more resistant at 25° C than the cells of *E. coli* at this temperature. With decreasing temperature increasing sensitivity in the solid state to ultraviolet irradiation is apparent. At −79° C the spores are 2·5 times more sensitive than at 25° C. The increased sensitivity becomes progressively less marked with temperatures lower than −80° C, and at −140° C the spores possess the same sensitivity to ultraviolet light as they do at room temperature. As the irradiation temperature continues to fall a marked and logarithmic increase in resistance is apparent. This logarithmic increase in resistance, represented by the equation $y = a + bt$ when $y = \log_{10} D_{90}$, would indicate that the resistance of *B. subtilis* spores to ultraviolet light at −269° C would be $3{\cdot}1 \times 10^5$ ergs mm^{-2} (D_{90}), and at −273° C, 4×10^5 ergs mm^{-2} (D_{90}). It is interesting that the resistance of the spores of *B subtilis* at − 190° C is the same as that of the extremely resistant bacterium *M radiodurans* at 25° C

The behaviour of *M radiodurans* at low temperatures is unlike that of any other bacterium thus far studied[1] There is little change in the sensitivity of this bacterium with phase change and low temperatures until an increase in resistance is seen at temperatures below − 60° C The very large increase in resistance between − 60° C and − 196° C follows a quadratic function represented by the equation $y = a + bt + ct^2$ At − 269° C the estimated value for the D_{90} is 1 7 × 10^7 ergs mm^{-2}, and at absolute zero 2 2 × 10^7 ergs mm^{-2} These figures assume no alteration in the shape of the dose response curve at temperatures at or near absolute zero, this assumption may well be incorrect as photochemical events at these very low temperatures could be anomalous A small number of experiments with *Serratia marcescens* indicate that it behaves towards irradiation with ultraviolet light at low temperatures in a manner similar to that of *E coli* in that the supersensitivity at − 196° C is less than at − 79° C The spores of two different strains of *B megaterium* and the spores of the fungus *Aspergillus nidulans* are considerably more resistant to lethal effects of ultraviolet light at − 196° C than at 25° C Rahn[6] has reported that the DNA of *Haemophilus influenzae* irradiated *in vitro* in a purified state is much more resistant to the inactivation of its transforming properties when irradiated with ultraviolet light at − 196° C than at 25° C

Why do the spores of *B subtilis*, the cells of *E coli* and the cells of *M radiodurans* behave so differently to irradiation with ultraviolet light at low temperatures? When *E coli* is irradiated with ultraviolet light at − 79° C fewer thymine dimers within its DNA are produced than at 25° C (ref 3), the lethal damage is much less photoreactivable[3] and there is an increase in the amount of protein cross-linked to DNA[2,3] Many bacteria, several bacteriophages and at least one species of yeast, *Saccharomyces cerevisiae*, are supersensitive to the lethal effects of ultraviolet light at − 79° C and it has been suggested that death is associated with the formation of a photoproduct not amenable to normal repair systems[2] It would seem probable that the lethal effects of ultraviolet radiation at subzero temperatures in the frozen states are dependent on the relative contribution of the three known events previously mentioned and the ability or lack of ability of an organism to repair the qualitatively different damage resulting from low temperature radiation *M radiodurans* is known to possess very efficient mechanisms for the repair of thymine dimer lesions and it may well be able also to repair low temperature lesions as well as to excise the smaller amounts of thymine dimer within DNA formed at low temperature An alternative possibility is that the low temperature lesion formed in most bacteria is not formed in *M radiodurans* We cannot explain the interesting biphasic response of spores It has been reported that a large amount of the thymine in the DNA of spores is converted into a photoproduct which is not of the usual type of cyclobutane dimer (personal communication from J Donnellan) At irradiation temperatures lower than − 80° C it is possible that the formation of the spore photoproduct or products is less efficient than at higher temperatures

Are the results presented in this account of any relevance to problems associated with solar irradiation of airborne micro-organisms? Sunlight is very effective in killing a number of viruses at normal temperatures[7] A recent study has demonstrated that the number of mutations induced by solar radiation at the surface of the Earth is as much as fifteen times greater when *E coli* is exposed at − 60° C than at 30° C (ref 8)

Quantitative analyses of the atmosphere at altitudes ranging from 3 to 27 km for various micro-organisms have been helped by studies with balloons[9] Yeasts, various moulds and several different species of bacteria, with the Micrococci predominating, were found at these heights At heights varying from 9–18 km the average number of micro-organisms is probably 6 per 100 m³ At 18–27 km the average number is 1 5 per 100 m³ At much lower altitudes considerable numbers of micro-organisms may be found Analysis of air over the Atlantic Ocean has revealed fungi to be widespread at concentrations as high as 200/m³ at 3 km above sea level[10] The temperature of the atmosphere decreases in the International Standard Atmosphere by 6 5° C/km up to 11 km At altitudes greater than 11 km the temperatures encountered by micro-organisms will vary in a complex manner At the outer limit of the stratosphere (48 km) the temperature will be approximately 10° C, but at the outer limit of the mesosphere (100 km) the ambient temperature will be as low as − 75° C Micro-organisms exposed to the increased ultraviolet flux, which will include a proportionately larger amount of the very damaging shorter wavelength radiations not filtered by the ozone, will almost certainly be in a desiccated, frozen or freeze-dried condition Little is known about the sensitivity of micro-organisms to ultraviolet light in these conditions The results with *M radiodurans* and bacterial spores suggest that great caution must be exercised before speculating on the ultraviolet sensitivity of airborne micro-organisms when a number of factors such as temperature and the state of the cell water are not considered

ASTRONOMY

Microwave Background in a Steady State Universe

It is widely believed that the microwave background radiation[1–10] discovered by Penzias and Wilson had its origin in a hot, early phase of the expanding Universe. The possibility has recently been considered[11,12], however, that it is instead a result of the thermalization of starlight by interstellar dust grains. It is claimed that this could explain the fact that the energy density of the 3° K radiation is very close to those of starlight, magnetic fields, turbulent gas motions and cosmic rays, all measured in the galactic disk, and also of the energy produced[13] by the conversion from hydrogen to helium of one-third the mean density of visible galaxies—a fraction which corresponds to the ratio of helium to hydrogen in young stars[14]. A paper by Zeldovič and Novikov[15] has already, in fact, considered and discounted this possibility, and the purpose of this communication is to draw attention to some difficulties particularly associated with the suggestions of Hoyle and Wickramasinghe[11] and of Narlikar and Wickramasinghe[12].

One obvious problem is that of accounting for the detection of the radiation at decimetre wavelengths because interstellar dust grains are likely[16] to have graphite cores surrounded by ice mantles with a diameter of about 10^{-5} cm. These grains would not usually be expected to radiate efficiently at wavelengths about 10^6 times their physical dimensions. Hoyle and Wickramasinghe[11], however, note that certain doped alkyl halide crystals have[17,18] narrow absorption bands at frequencies near 300 GHz and they suggest that interstellar dust grains would also be expected to contain impurities which might radiate at these or lower frequencies. Narlikar and Wickramasinghe[12] develop this train of thought and claim that dust grains in a galaxy could absorb optical and ultraviolet radiation from stars and re-emit the energy as strong infrared radiation in frequency bands at about 300 GHz with an intensity equivalent to about one-third of the entire luminosity of the galaxy. The observed microwave radiation is then, in their view, attributable to the integrated and red-shifted infrared emission from all the galaxies in a steady state universe. It is, in any case, apparent from the observed isotropy[19] of the radiation and the absence of any detectable galactic absorption in the microwave spectra of radio sources that the microwave background radiation cannot be merely a phenomenon confined to our galaxy. They show that such an integrated radiation component would have a spectrum $\mathcal{J}(\nu)\propto\nu^3$ and they believe that the difference between this and the observed spectrum $\mathcal{J}(\nu)\propto\nu^2$ could be a result of distinct impurities oscillating at particular frequencies such that the observed spectrum depends in a fortuitous manner on the frequencies of observation.

There are serious weaknesses in this interpretation which must be overcome before it can be regarded as a remotely plausible model for the origin of the radiation.

(1) Narlikar and Wickramasinghe carry out a calculation intended to show that the observed brightness is not inconsistent with the integrated thermalized optical radiation from galaxies in a steady state universe. Because the total energy density of the microwave radiation is about 6×10^{-13} erg cm^{-3}, it follows that the total optical radiation from galaxies in a steady state universe would have to be of at least this value if there were no thermalization. A calculation of this quantity is to be found in a recent review by Davidson and Narlikar[20] and is given as 2.4×10^{-15} erg cm^{-3}, that is, more than two orders of magnitude less than that of the microwave radiation. This discrepancy was noted in the review where it was said to be "by a factor of at least 400" (p. 587) but is not mentioned by Narlikar and Wickramasinghe. They do, however, suggest that because of the present uncertainty in the ultraviolet output of a galaxy it may be that the total ultraviolet emission of young spiral galaxies exceeds that of the visible emission by a factor of 10 to 100. Subsequent thermalization, it is suggested, could produce microwave radiation and the "microwave power could exceed the visible power by a factor of about 100". If this is so for our own galaxy, then the microwave frequencies emitted must avoid all frequency bands in which observations have so far been carried out. Penzias and Wilson[21], for example, have measured the brightness of the microwave radiation from the galactic disk at a frequency of 4.08 GHz and have shown it to be entirely consistent with lower frequency observations which set a value of $\approx10^{39}$ erg/sec on the total galactic radio emission, at least four orders of magnitude less than the total optical emission. An upper limit on the galactic radiation at 9.4 GHz can also be set from the measurements by Partridge and Wilkinson[19] which are again consistent with this value. At still higher frequencies ($\approx10^3$ GHz) Hoffmann *et al.*[22] have put low upper limits to the brightness temperature of any discrete source in the northern sky, that is, $<10°$ K for a black-body subtending 2° or more and $<0.6°$ K for an optically thin "grey-body" which gives a Rayleigh–Jeans (ν^2) spectrum in this frequency range. Any substantial increase in the energy density of microwave radiation in the galaxy would be extremely difficult to reconcile[23] with the observed energy spectrum of cosmic ray electrons which interact with radiation quanta by the Compton effect and would also, of course, destroy the agreement with the various energy densities of starlight and cosmic rays which the theory was put forward to explain in the first place.

(2) Neither paper includes a discussion of the obvious and vital differences between the optical properties of alkyl halide crystals and of interstellar dust grains of the ice coated graphite type proposed by Wickramasinghe[16]

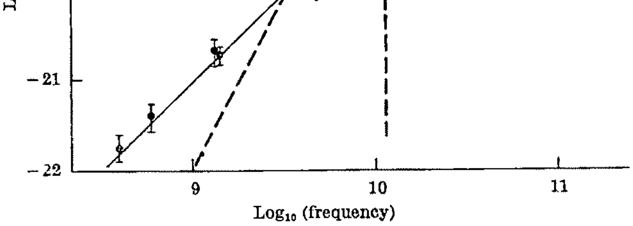

Fig. 1. The plotted points show the measured values of the brightness of the "excess" microwave background radiation[1–10]. That at 115 GHz is derived from cyanogen excitation[25,26]. The solid line is a Planck spectrum corresponding to a temperature of 2.68° K and the dashed lines[12] show the type of emission which Narlikar and Wickramasinghe believe could originate in interstellar dust grains. The units of brightness are W m^{-2} Hz^{-1} ster^{-1} and of frequency are Hz.

Because graphite is a semi-metal with a low resistivity[24] at the temperatures[16] of the grains, these will behave as Hertzian dipoles in this frequency range and radiate with power $\propto\nu^4$ rather than in discrete bands or lines. There may, of course, be impurities in the ice coating, but if these behave as do the impurities in the potassium chloride studied by Sievers[17], the absorption coefficient ($\approx 2·5$ cm^{-1}) is negligible compared with that of the graphite.

(3) At the time of submission of the communication by Narlikar and Wickramasinghe, measurements of the brightness of the microwave background had already been published[1–6] for five wavelengths, two of which were, admittedly, very close. In trying to fit the observed ν^2 spectrum with the calculated ν^3 spectra reference was made to two of these only. At the present time, measurements[1–10] at twelve wavelengths over a frequency range of 90:1 (or 280:1 if the cyanogen excitation results[25,26] are included) are available. They are all, with one possible exception[8], consistent with a Planck spectrum[7] at a temperature of 2·68° K (see Fig. 1). It would clearly require a very special distribution of impurity oscillators, each producing a spectrum $\mathcal{J}(\nu)\propto\nu^3$, to fit the observed values.

We conclude with Zeldovič and Novikov[15] that radiation from dust grains is not a satisfactory alternative to the primordial origin of the cosmic microwave radiation.

We thank Professor J. C. Phillips for a helpful discussion on the optical properties of crystals.

3C390·3, a Second Variable *N*-Galaxy

Oke[1] and Sandage[2] have shown that the *N*-galaxy 3*C*371 is variable. This communication reports the discovery that the similar system 3*C*390·3 has been varying by up to about 1·5^{m} during the past 70 years. This is interpreted as showing that at least some quasars are cosmological.

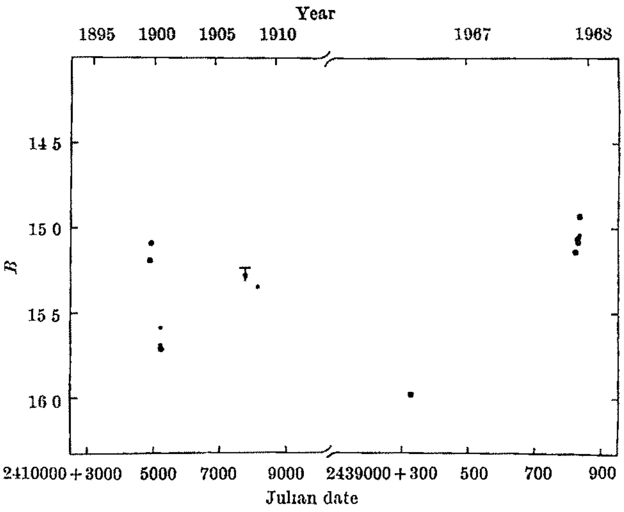

Fig. 1. Light curves of 3*C*390·3 for 1894 to 1910 and for 1966–67. The larger points have errors of less than 0·07^{m}, the smaller ones have larger errors. The arrow denotes a lower limit to the magnitude.

The radio source 3*C*390·3 is listed by Wyndham[3] as being identified with an *N*-type galaxy. Sandage[4] has obtained a spectrum of the galaxy which shows nine emission lines, some of which are 50 Å broad, giving a red-shift of 0·0569. It also shows a large ultraviolet excess similar to those found in other *N*-galaxies and quasars. We obtained one plate of the galaxy during August 1966 on the 26 in. *f*/10 refractor at Herstmonceux. Following the discovery that 3*C*371 was variable, we have obtained a further series of plates of 3*C*390·3 on the same instrument. These showed that 3*C*390·3 had varied by about 1^{m} in 16 months. This discovery prompted a search for old plates of the field of 3*C*390·3. We discovered a number of plates taken on the 13 in. astrographic refractor at Greenwich between 1894 and 1908 in connexion with the astrographic charts, eight of which were of sufficient depth and quality for photometry. These showed that 3*C*390·3 had also been varying at that time. A photographic transfer plate taken on the same 13 in. refractor, now at Herstmonceux, was used to transfer the photoelectric standards set up by Sandage[5] in the nearby field of the cluster *NGC* 188 into the field of 3*C*390·3. Past experience[6] shows that this technique yields comparison sequences good to about 0·1^{m}. All plates were measured on a Sartorius Iris diaphragm photometer. The resulting measures were reduced to give magnitudes for the galaxy by a computer programme fully described elsewhere[7].

The full results of this reduction are listed in Table 1 and displayed in Fig. 1. The modern plates were taken on Eastman Kodak IIaO emulsion without filter which gives approximate *B* magnitudes. The old plates were taken on a variety of blue sensitive emulsions, so there may be small differences of system. The observed variation, however, is so large that it is not in doubt, particularly because plates taken on different emulsions in the same month agree within their errors. Some modern plates (marked with an asterisk in Table 1) were taken deliberately out of focus in order to show that the non-stellar nature of the galaxy does not affect our results. That this is so can be seen from the agreement of plates taken on the same night. In fact, 3*C*390·3 and other *N*-galaxies are only just non-stellar on the Palomar Observatory Sky Survey (POSS) charts. Also listed in Table 1 are the photoelectric *B* magnitude published by Sandage[4] and a magnitude estimated by eye from the blue POSS chart. The most rapid variations we have recorded are 0·6^{m} in 10 months during 1899–1900 and 0·8^{m} in 16 months

during 1966–67 It is also probable that the 0 1^m increase during November and December 1967 is real

Sandage[2] has published a two colour diagram which shows that the variable *N*-galaxies 3*C*371 and 3*C*390 3 are the two *N*-galaxies which most closely resemble quasars in their observed colours He also points out the similarity of colours and spectra of 3*C*390 3 and the quasar Ton256 (ref 4) These similarities and the so called "continuity" arguments of Heeschen[8] and Ryle and Longair[9] raise the question of the relation between quasars and *N*-galaxies In Table 2, we present the properties of 3*C*390 3 and 3*C*371 together with three sources listed as quasars by Barbieri *et al* [10] and Burbidge[11] These three quasars lie nearest to the Hubble relation in the magnitude–red-shift diagram.

We give the observed galactic latitude (b^{II}), red-shift (z), B magnitudes—at maximum for the *N*-galaxies—and flux density at 178 MHz (S_{178}) We also present B' and S'_{178}, the B magnitude and flux density at 178 MHz which would be observed if the other sources were in the same position in space as 3*C*390 3 To compute B' we have assumed that the red-shift is cosmological, that the *K*-correction for quasars given by Sandage[12] applies and that the absorption in the galaxy is given by $A_B = 0\ 12^m$ cosec b^{II} We have computed S'_{178} similarly assuming a cosmological red-shift and a *K*-correction based on a straight spectrum ($S \propto \nu^{-\alpha}$ for 3*C*47 $\alpha = 0\ 82$ from Conway *et al* [13], otherwise no values of α are available in the literature and we have assumed $\alpha = 0\ 7$) Note that for Ton256 and *PHL* 1194 the limit $S_{178} < 2$ is based on the absence of these sources from the fourth Cambridge catalogue of radio sources[14,15]

It is noticeable that the values of B' of all these sources are closely similar If the *N*-galaxies were at a distance given from the red-shifts of the quasars by the Hubble law, they would probably not seem to possess any nebulosity Indeed, one might otherwise ask why we have not observed *N*-galaxies at much greater distances Thus it is quite possible that the "quasars" listed in Table 2 are at cosmological distances and if brought closer would appear very similar to the *N*-galaxies We note that a very deep plate of another quasar, 3*C*48, by Sandage and Miller[17] does show nebulosity but beyond the range of the Palomar Observatory Sky Survey plates

The situation is not so clear in the case of S'_{178}, nonetheless it is apparent that the flux density of 3*C*390 3 is bracketed by other sources hitherto regarded as quasars It is also interesting that both 3*C*390 3 and 3*C*47 are radio doubles with very similar physical separations[9]

It seems that the arguments for the continuity of quasars and radio galaxies understate the case We propose that these three "quasars" and possibly others are, in fact, *N*-galaxies and so are at cosmological distances It is perhaps particularly provoking that 3*C*47 is an archetypal quasar, being the third[16] to have had its red-shift determined It may be, however, that quasars comprise more than one type of object so that whether the red-shifts of all quasars are cosmological is still an open question

We thank Miss Rosemary Brett for assistance in measuring the plates and Dr D. Lynden-Bell for directing our attention to the old astrographic plates We are also grateful to Mr M Rowan-Robinson for first directing the attention of one of us to the problem of *N*-galaxies

Alfvén's Critical Velocity Hypothesis

IN his theory on the origin of the solar system[1], Alfvén makes an assumption which is central to the entire theory[2] This assumption is that when there is a relative velocity between a plasma and a neutral gas in the presence of a magnetic field, a strong ionization process will set in when the relative velocity reaches a critical value U_{crit} such that

$$\tfrac{1}{2} m_g U^2_{crit} = eV_i$$

where m_g and V_i are the mass and ionization potential of the gas atom Using this assumption, Alfvén has been able to predict fairly accurately the mass distribution of the planets and satellites in the solar system A study of the ionization mechanism leads to some difficulties, however, first, the threshold energy for ionization in a collision between a gas atom and an ion of the same gas is $2\,eV_i$ (ref 3) and, second, the ionization cross-section of ions is very small compared with that of electrons, except at very high energies It has been suggested[4] that the ionization must be caused by the electrons and that energy is transferred from the ions to the electrons by some kind of space charge mechanism which is not discussed in detail The purpose of this communication is to point out three simple ionization mechanisms which lend support to the critical velocity hypothesis

In Alfvén's theory the situation considered is that of a plasma held stationary by a magnetic field in a stream of neutral gas The electrons in the plasma will be heated by collisions with the gas stream, and the equipartition principle shows that with elastic collisions only the average energy of the electrons is given in terms of the gas stream velocity U by

$$\tfrac{1}{2}m_e \langle v_r^2 \rangle = \tfrac{1}{2}m_g U^2$$

Inelastic collisions will tend to reduce the electron energy, but this relationship shows that when U is near U_{crit} the electron energy is an appreciable fraction of eV_i and consequently ionization is to be expected By using an equivalent field technique[5] which is closely related to the equivalent pressure technique of Blevin and Haydon[6], the electron ionization frequency can be found as a function of U alone from the data available on the electrons' drift velocity and ionization frequency in the absence of a magnetic field The electron ionization frequency for helium is shown in Fig 1, which also gives U_{crit} for helium

The relative kinetic energies of interest measurements[7] show that the charge transfer collision cross-section for atomic helium ions in helium is much larger than the elastic cross-section, and at these energies elastic collisions show pronounced forward scattering[8] For these reasons, charge transfer collisions are the most important, and it is a characteristic of these collisions that after the collision the ion has very nearly the same velocity, that is, U, as the atom had before it The ion will then move through its Larmor orbit in the magnetic field with a constant velocity and the ion energy relative to the gas stream will then be $(m_i = m_g)$

$$m_g U^2 (1 - \cos \omega_i t)$$

The average ion energy is $m_g U^2$ and this equals the threshold energy for ionization $(2\,eV_i)$ when $U = U_{\text{crit}}$ The peak energy is $2m_g U^2$, which is 98 eV in helium when $U = U_{\text{crit}}$, and these high energies can lead to appreciable ionization by the ions The ionization frequency of the ions can be averaged around the orbits[5] of the ions and the result, based on Rostagni's[9] ionization cross-sections, is shown in Fig 1 It can be seen that the ionization frequency of the ions is greater than that of the electrons although the ionization cross-section of the ions is much smaller than that of the electrons This is because the energy of every ion is above threshold in part of its orbit, if U is large enough, while only the small fraction of electrons in the high energy tail of the electron energy distribution can ionize

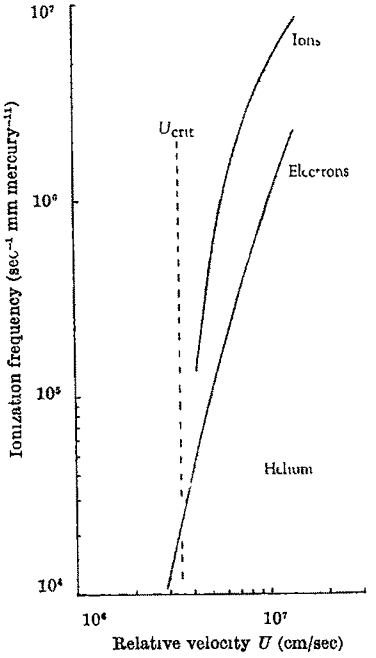

Fig 1 Plot of ionization frequency against relative velocity U between the plasma and the neutral gas for electrons and ions of helium

The atoms formed in charge exchange collisions will move in straight lines with almost the same velocity as the ion had before the collision This means that these atoms will have on average an energy, relative to the gas stream, which is roughly equal to the ion energy (In the constant mean free time approximation the "new" atom and ion energies are equal[5]) Also the ionization cross-section for atom–atom collisions[10] is similar to that for ion–atom collisions, so that the ionization frequency of the "new" atoms is similar to that of the ions The "new" atoms may contribute more to the total ionization than the ions, depending on the density of "new" atoms in comparison with that of the ions

It is suggested that the critical velocity hypothesis is a consequence of the fact that the ionization frequencies of the electrons, ions and atoms formed in charge exchange collisions all become appreciable and increase rapidly with U when U is near U_{crit} By lending support to the critical velocity hypothesis these results indirectly support Alfvén's theory of the origin of the solar system, but it is pointed out that the details of Alfvén's theory might have to be modified to take account of the possible effects of the ionization caused by the ions and atoms formed by charge exchange

Results from experiments with partially ionized crossed field homopolar discharges[11,12] can be explained if the relative velocity between the gas and plasma is limited to a value near U_{crit} (ref 12) If the theory of Drobyshevskii[13] is extended to include the effects of ionization by the ions and atoms formed by charge exchange collisions, fair agreement with experiment is obtained[5] It turns out that in these experiments the density of "new" atoms is higher than the ion density so that most of the ionization is caused by the atoms formed by charge exchange

PLANETARY SCIENCE

Northward Drift of India—Examination of Recent Palaeomagnetic Results

Initial surveys[1-3] of the palaeomagnetism of the Deccan traps showed that there is an apparent decrease of palaeomagnetic inclination with altitude above sea level This was interpreted[2,4] as indicating a continuous northward movement of India during the time when the traps were being extruded It was pointed out however, that the observations could also be explained in terms of partial magnetic instability causing the directions to be pulled towards the present geomagnetic field Sahasrabudhe[5] has now made a very extensive palaeomagnetic study of the Deccan traps using magnetic cleaning techniques His aim was to try to use the palaeomagnetic directions for stratigraphic purposes and he did not attempt to

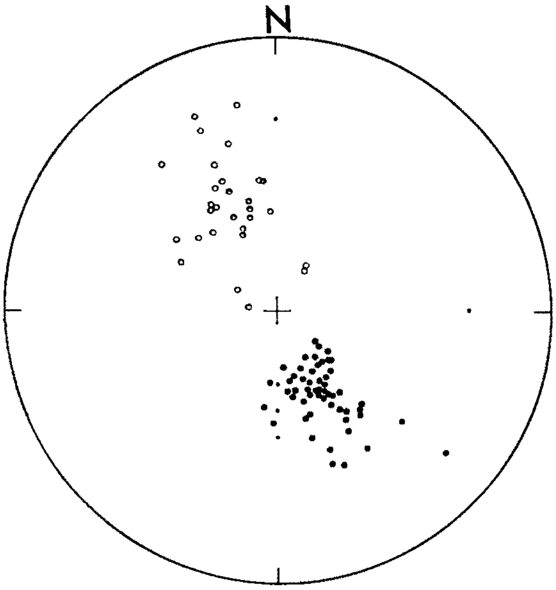

Fig 1 Stereographic projection of directions of magnetization at ninety-two sites in the Deccan traps ●, Lower hemisphere, ○, upper hemisphere

analyse his data for normal palaeomagnetic purposes I have made a complete analysis of his data and the purpose of this communication is to demonstrate that the earlier results are more likely explained in terms of viscous magnetization This conclusion leads to some consequences regarding the northward drift of India during the Tertiary

Approximately a thousand samples were analysed by Sahasrabudhe from seventy-one sites in a minimum of thirty flows and from thirteen dykes intruding them The sites were spread over the length and breadth of the area at present covered by the traps and over the entire thickness of about 4,000 ft Flows below an altitude of 2,000 ft were usually reversely magnetized (positive dips) and those above this level were usually normally magnetized (negative dips) The more detailed collection coupled with magnetic cleaning studies shows that there is no systematic change in inclination through the sequence as was suggested by the earlier results The lower (reversed) traps range in inclination in no systematic manner from +70° to +27° and the upper (normal) traps likewise range from −77° to −19° Normally magnetized dykes intrude both the lower and upper traps, but reversely magnetized dykes were not found intruding the normal ones Because the normally magnetized traps always overlie the reversed ones and are therefore stratigraphically younger, a distinction can be made between the lower and upper traps on the basis of polarity and the overall means for the two groups are given in Table 1 This analysis was not carried out by Sahasrabudhe, and for completeness I have also included results from eight sites in four areas not sampled by him[6,7] In each case, magnetic cleaning techniques were also carried out

Table 1 shows that ninety-two sites have been sampled in the flows and dykes of the Deccan traps and this is now one of the most thoroughly sampled formations in the palaeomagnetic literature The means of the two groups differ by 172 ± 8°, so that they both represent the same axis of rotation within the experimental errors The directions of magnetization are illustrated in Fig 1 The scatter of directions can readily be explained in terms of secular variation[8,9], and in neither case can it be shown[10] that the distribution of directions is non-Fisherian[11] The data therefore strongly support the contention that little or no polar movement took place during the period of extrusion of the Deccan traps and that the centre of the Indian subcontinent was situated about 30° S throughout this time

Table 1 PALAEOMAGNETIC RESULTS FROM THE DECCAN TRAPS, INDIA

	Directions						Pole position		
	No of site	Declination	Inclination	Resultant of N unit vector	Estimate of precision (ref 11)	α_{95}	Lat N	Long E	A_{95}
Upper traps (negative dips)	29	335	−45	27 185	15 4	7	37	102	8
Lower traps (positive dips)	63	152	+53	61 105	32 7	3	30	101	3
Overall mean	92	153	+51	88 114	23 4	3	33	102	3

α_{95} and A_{95} are the radii of 95 per cent circles of confidence

Recently, some potassium–argon age determinations have been made at the Department of Terrestrial Magnetism, Washington[12] Although the five determinations range from 42 to 65 × 10⁶ yr, the oldest age is from the overlying Pavagarh basalt, so there is the possibility of argon loss from some of the samples Assuming the age to be represented by the oldest determination, this places the traps at the Cretaceous–Tertiary boundary[13] Some clue as to the time covered by the extrusion of the traps is given by the fact that in spite of very detailed sampling only one reversal of the geomagnetic field is recorded in the 4,000 ft sequence Recent observations from magnetic anomalies and ocean-floor spreading since the late Cretaceous have led Heirtzler and his colleagues[14] to deduce a possible geomagnetic time scale back to 75 × 10⁶ yr. This analysis suggests that periods of normal or reversed polarity have persisted for no longer than 2 × 10⁶ yr at a time since the late Cretaceous If this is the case, then it seems unlikely that the Deccan traps cover a period of much longer than 5 × 10⁶ yr

Polar movement with respect to India since the Upper Permian is illustrated in Fig 2 It is not clear from the available data whether there is any real difference between the Upper Permian and Jurassic poles, although there is a significant difference between the Jurassic and Cretaceous poles It is quite clear from Fig 2, however, that the important polar shift with respect to India occurred between Deccan trap times and the present During this time the central part of India moved from latitude 30° S to 20° N If India had reached its present position by the time of formation of the Himalayas in, say, the Miocene, then this 50° change of latitude took place over about 50 × 10⁶ yr This corresponds to an

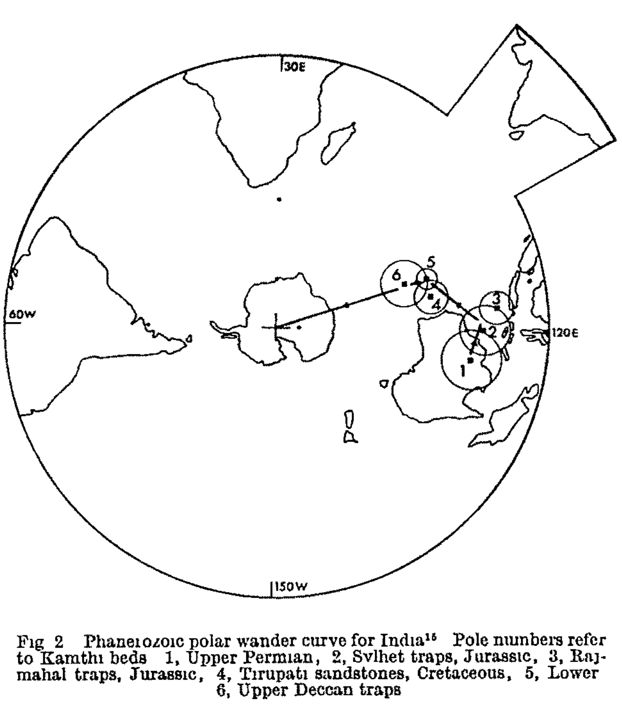

Fig 2 Phanerozoic polar wander curve for India[15] Pole numbers refer to Kamthi beds 1, Upper Permian, 2, Sylhet traps, Jurassic, 3, Rajmahal traps, Jurassic, 4, Tirupati sandstones, Cretaceous, 5, Lower 6, Upper Deccan traps

average rate of drift of India of 10 cm/yr during the Tertiary This is considerably greater than the average rate of about 5 cm/yr which I suggested[15] occurred between the Gondwanic continents during the break-up of Gondwanaland since the Upper Cretaceous It will be interesting to see in future whether these palaeomagnetic deductions of drift rates are substantiated by sea floor spreading rates south of India

Glasgow University Exploration Society Expedition to Inishtrahull

A GLASGOW University Exploration Society expedition to the island of Inishtrahull (lat 55° 26′ N, long 7° 14′ W), which is 5 miles from the northern coast of Donegal, was made during June 23–July 4, 1967, under the leadership of John Smart The rocks of the island have been both compared and correlated with the Lewisian gneisses of north-western Scotland[1,2], and the geological investigations carried out by the ten members of the expedition, under the direction of Dr D R Bowes and Dr A M Hopgood, are in continuation of Lewisian investigations being carried out in the Departments of Geology of the University of Glasgow and the University of St Andrews The island is approximately 1 mile long, in an E N E–W S W direction with almost uninterrupted clean coastal exposures on a broad wave-cut platform or on accessible cliffs Inland elevated parts (up to 141 ft above sea level at the western end), with outcrops of gneiss and related rocks, occur on either side of a low central area The island is less than 200 yd across in part of this central area and the gneiss complex largely covered by post-glacial bedded raised beach deposits (at approximately 40 ft O D) and soil On the high ground at the western end of the island stands the Inishtrahull Light

Quartzo-feldspathic and related gneisses make up much of the rock outcrop Some are strongly foliated and have a well developed mineral lineation other lithological units show little expression of planar or linear fabric elements One massive unit of calcium-rich epidote-bearing gneiss has a chemical composition similar to that of a calcareous pelite Its occurrence among a lithologically layered assemblage of gneisses suggests that the metamorphic complex largely represents a supracrustal series, possibly of sedimentary derivation There is evidence of metamorphic reconstitution at amphibolite facies, but over large areas the results of retrogressive deformation accompanied by considerable cataclasis constitute the dominant fabric elements of the rocks Among these crushed units are long narrow zones of cataclasite and small veins of pseudotachylite have been observed

Amphibolite occurs as small lensoid rock masses and in parts as fragments in agmatite A narrow, elongate lens of mafic rock with relict pyroxene and a ribbed outcrop, resembling that of layered ultrabasic bodies in the Lewisian of north-western Scotland[3], suggests that there was igneous activity before the development of the dominant foliation There are minor intrusions, including two sets of pegmatite veins Their respective times of emplacement in relation to the history of the gneiss complex can be determined from the various effects of metamorphic reconstitution and deformation exhibited In one case the evidence is based on the presence of an exceptionally well-displayed set of folded joints A number of unmetamorphosed dolerite dykes with an approximately easterly trend cut the gneiss complex They are presumed to be of Tertiary age

The effects of six phases of folding and associated deformation have been observed in the gneiss complex Of these, the earliest recognized was broadly co-eval with the formation of the gneissose foliation The structures which exert the dominant control on the distribution of the lithological units, and with which the development of the strong retrogression and cataclasis are related, were formed during the second deformational phase These structures deform both lithological layering and gneissose foliation The effects of the third and fourth deformational phases include some new mineral growth as well as the warping of the major structures while the final two phases are only locally expressed as very open folds In summary the sequence of geological events shown by the gneiss complex is as follows

(1) The formation of a lithologically layered sequence, possibly as the result of sedimentary processes

(2) The emplacement of mafic-rich igneous masses

(3) The development of gneisses associated with tight isoclinal folding of the lithological layers and tectonic disruption, in parts with the formation of agmatite Metamorphic reconstitution took place and the dominant foliation developed parallel to the axial planes of the isoclinal folds, hence generally parallel to the lithological layering

(4) The emplacement of basic igneous minor intrusions

(5) The formation of folds of varying style (isoclinal, asymmetrical, chevron, open) which fold the foliation and exert the most important control on the distribution of the lithological units Statistical analysis of fabric elements confirms field observations that the folds have sub-vertical axial planes and indicates that they plunge at approximately 15° towards 055° The style of the structures and the related cataclasis indicate deformation at a relatively shallow level in the crust Subsequent uprise of quartzo-feldspathic pegmatitic material from deeper levels was controlled by the axial planes of these folds

(6) Successive emplacement of acid and intermediate minor intrusions at the close of the second deformational phase Quartzo-feldspathic sheets, much sheared parallel to their margins, are cut by more mafic material which shows some planar alignment of minerals parallel to the intrusion walls

(7) The development of open folds with sub-vertical axial plane cleavage which trends N N E–S S W and cuts the minor intrusions of (6) These structures were superimposed on an already deformed foliation, and so the angle of plunge of the folds varies

(8) The formation of open folds with sub-vertical axial planes which trend N W–S E These folds are expressed on map scale as warps on the steep limbs of the 55° trending structures and have an associated fine planar mineral growth In one place a fold of this phase has been observed to deform the axial plane of a fold formed during event (7)

(9) The localized development of open concentric folds with sub-vertical E -W trending axial planes No related linear or planar fabric elements have been observed but crescent-shaped patches of quartz occur in some fold crests and troughs

(10) The localized development of very open folds plunging at low angles towards the north-east These folds are apparent only where they are superimposed on parts of the principal structure with flat-lying foliation

Quartzo-feldspathic pegmatite veins and, more commonly, quartz veins, occur and these follow the foliation on vertically disposed limbs of second generation folds They seem to be unaffected by events (7) and (8) but their relationships with events (9) and (10) are not clear

In the absence of radiometric dates, the absolute age of the gneiss complex of Inishtrahull cannot be determined There is, however, great similarity, both in rock types and also in tectonic and metamorphic histories, to the Lewisian of parts of the north-west Highlands of Scotland[4] and particularly to the Lewisian of Barra[5] and Mingulay[6,7] in the Outer Hebrides In each case (*a*) the earliest recognized phase of tectonics is associated with intense shear folding and the development of the dominant foliation and of autochthonous granitic rocks, (*b*) the principal structural pattern is related to deformation of the dominant foliation, the development of asymmetrical folds by a combination of concentric and shear movement and the later uprise of pegmatitic material along the axial planes of these folds Also (*c*) the open folds, formed largely by concentric movement, but with related development of fracture cleavage, deform both the dominant foliation and the major structures, and in the case of Inishtrahull, Mingulay and Barra, precede the further uprise of pegmatitic material Also in the case of the gneiss complexes of the three islands, the final tectonic phase is shown by very open concentric folds

While such similarities do not constitute definite proof of a correlation, and comparable features have been observed in other metamorphic terrain, it seems likely that there is general correspondence of geological histories of the Lewisian gneiss complex of the southern regions of both the north-west Highlands of Scotland and the Outer Hebrides[8] and the gneiss complex of Inishtrahull If this is proved to be the case, both the existence of Lewisian rocks as far south as Inishtrahull and the distinctive features of the gneiss complex there (particularly the evidence for a moderately shallow depth during the second deformational phase) will add considerably to our knowledge of the Lewisian.

The expedition received financial assistance from the University Court of the University of Glasgow and help from the Commissioners of Irish Lights We thank the British Egg Marketing Board, Erin Foods, Ltd , Guinness Group Sales (Ireland), Ltd , I H Lavery and Co , Ltd , A Massey and Sons, Ltd , Thos Mitchellhill, Ltd , J Paterson and Son, Ltd , Unigate, Ltd , A Wander, Ltd , and the University of Glasgow Student Health Service for their assistance

Characterization of Carbonaceous Material from the Puerto Rico Trench of the Atlantic Ocean

Samples of two types of rocks containing organic material were collected from 65° 41′ 24″ W , 20° 15′ 58″ N during a cruise of the R V *Chain* of the Woods Hole Oceanographic Institution to the north wall of the Puerto Rico Trench (Fig 1) One of the samples is soft material, predominantly organic (*Ch* 34–*D*3) The other sample is hard material, a mudstone into which organic material seems to have migrated and subsequently been silicified (*Ch* 34–*D*3–182) This organic material and the associated basalts, limestones, cherts and siliceous mudstones were collected from depths of between 3,350 and 3,450 fathoms[1,2] These are the first organic samples obtained from ocean depths of this magnitude The limestones collected in the same dredge haul are Cenomanian in age[3], however, the age of the organic material is unknown

Characterization of the carbonaceous material is interesting because of its possible relationship to the principal types of terrestrial liquid and solid carbonaceous material such as coal, petroleum, and shale oil Characterization of the organic material may present clues to its origin It may have been transported to the site of deposition by living organisms, such as marine worms, which live in the deepest part of the Puerto Rico Trench, or it may have been deposited concurrently with the other sedimentary rocks, however, the carbonaceous material present in the siliceous mudstone indicates that the organic material postdates the sedimentary rocks

Another point of interest is the possible economic value of the carbonaceous materials at the bottom of the ocean, although it is very unlikely that such materials will have economic value in the foreseeable future

The original sample of semi-consolidated substance (soft material) was 15 cm × 8 cm × 3 cm in size, light in weight (real specific gravity of 1 50), porous, brown to brownish black in colour and easily ignited Thin-section analysis indicated that inorganic particles the size of clay made up 2–4 per cent of the sample X-ray diffraction analysis showed that the clay mineral was montmorillonite (expanded to 17 Å on treatment with ethylene glycol, but gave a broad peak indicating that the montmorillonite is poorly crystalline) The total content of minerals is appreciable, as indicated by the ash yield

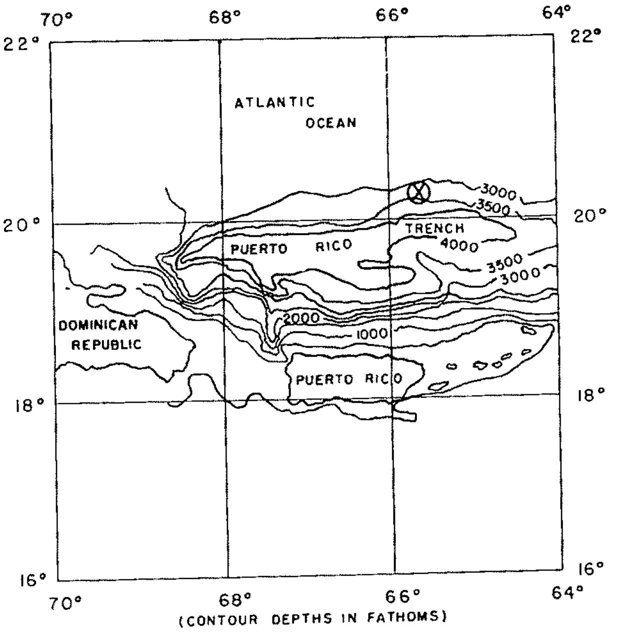

Fig 1 Location map, ⊗ shows collection site

Table 1 EMISSION SPECTROGRAPHIC ANALYSIS OF SOFT MATERIAL (SEMI-QUANTITATIVE)

Element	Weight per cent
Silicon	5
Magnesium	1–5
Aluminium	1
Iron	1
Calcium	0 5
Sodium	0 05
Titanium	0 05
Vanadium	0 05
Manganese	0 05
Chromium	0 01
Copper	0 01
Boron	Trace

determined by combustion, 27 5 per cent The metallic elements determined by emission analysis are given in Table 1

The original sample of silicified carbonaceous mudstone (hard material) was 13 5 cm × 10 cm × 2 5 cm in size was very fine grained and black to olive grey in colour, with the dense black portion (real specific gravity of 2 25) being surrounded by porous olive grey material which was poorly consolidated (real specific gravity of 2 42) The carbonaceous material within the black portion appeared to have disseminated into the siliceous mudstone and was then concentrated there as a hard, dense material as a result of subsequent silicification of the central portion of the sample The mineral portion of this sample consisted of 45 per cent quartz with minor tridymite, 1 per cent calcite that was less than 0 002 mm in size and subhedral in shape, 1 per cent smectite which was disseminated throughout, and 1 per cent chlorite which occurred as stringers and blebs Infrared spectra of the original rocks substantiated part of the X-ray diffraction analyses, but added no further information The carbonaceous material representing about 10 per cent of the sample was yellowish brown in plane light and isotropic between crossed polarizers Poorly preserved microfossils consisting of radiolaria, which were replaced by quartz, comprise 20 per cent of the sample Unfortunately, the microfossils were too poorly preserved for identification

Of several solvents investigated for extraction in organic studies, pyridine seemed to give the best results The yield of pyridine extract was 1 5 per cent for the soft material and 0 82 per cent for the hard material Dioxane extraction of the portion of the soft material soluble in pyridine gave a yield of 80 per cent of material suitable for ultraviolet spectral measurements Ultraviolet and visible and infrared spectra were obtained from the original and extracted material

Ultraviolet and visible spectra for the extracts of the soft and hard materials were identical The spectrum of the soft material is given in Fig 2 Two strong bands at 412 and 658 mμ were observed in the visible spectrum (pyridine solvent) Moderate bands were found at 695, 600 and 502 mμ, and a weak band at 557 mμ In the ultraviolet region moderate bands occurred at 250 and 301 mμ (dioxane solvent) Because of the strong bands observed in the visible spectrum an attempt was made to obtain a visible spectrum of the original rock The spectrum obtained (Fig 2, curve *C*) indicates that intense absorbers are present, it is not usual to obtain structured visible spectra directly on carbonaceous rocks

The spectra seem to be similar to spectra of porphyrins, or the related bile pigments[4] or the metal complexes of these The strongest band, 412 mμ, is the Soret band familiar in spectra of porphyrins and related materials Semi-quantitative measurements based on pure compound spectra for metal complexed bile pigments and porphyrins yield results in the range of 1 per cent for the content of the material producing this spectrum The bile pigments and the porphyrins have similar structures, both involving a group of four pyrrole rings[4] The nitrogen content of the carbonaceous materials is high enough to accommodate such structures as shown by the ultimate analyses (Table 2) A high sulphur content is also indicated in Table 2

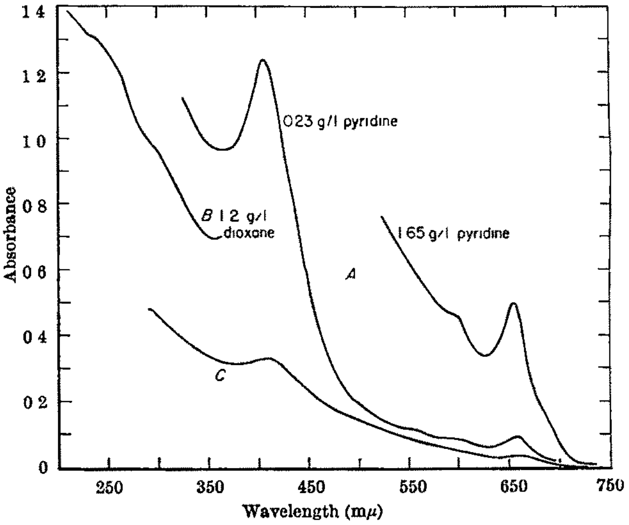

Fig 2 Ultraviolet and visible spectra of carbonaceous materials from the Puerto Rico Trench, curve *A*, pyridine extract of soft material, 1 cm path, curve *B*, dioxane solubles from pyridine extract of soft material, 2 cm path, curve *C*, potassium bromide pellet of original soft material

A visible spectrum of the kerogen concentrate from oil shale (not shown) also shows weak bands at 412 and 270 mμ and very weak bands at 637 and 312 mμ The specimens do not fluoresce under mercury 2537 Å light

Infrared spectra of extracts of the ocean rocks initially indicated some interference caused by traces of mineral matter From dilute solutions of the extracts the mineral matter was allowed to settle out, the solutions were decanted and spectra nearly free of mineral interference were obtained These spectra, shown in Fig 2 along with a spectrum of kerogen from oil shale (kerogen sample supplied by J Cummins, Bureau of Mines, Petroleum Research Center, Laramie, Wyoming), indicate intense OH absorption (about 3,400 cm^{-1}), intense aliphatic CH (about 2,900 cm^{-1}), very weak aromatic CH (3,030 cm^{-1}), strong carbonyl absorption (1,700 cm^{-1}), strong absorption caused by $-CH_3$ groups (or $-SO_2-$ groups or both) (1,375 cm^{-1}), strong absorption in the region indicating carbonyls in either acids or esters (1,200 to 1,250 cm^{-1}) and weak absorption in the aromatic band region (650 to 900 cm^{-1}) There is some indication of aromatics but the spectrum is principally that of aliphatic substances The infrared spectra of the original rocks were also recorded (not shown), the spectra of the rock samples are apparently identical to the spectra of the extracts obtained from them For the soft material it was possible, in spite of the spectral interference of the minerals, to observe all the principal spectral bands produced by the entire carbonaceous

Table 2 ULTIMATE AND PROXIMATE ANALYSIS OF CARBONACEOUS ROCKS* FROM PUERTO RICO TRENCH (SPECIFIC GRAVITIES)

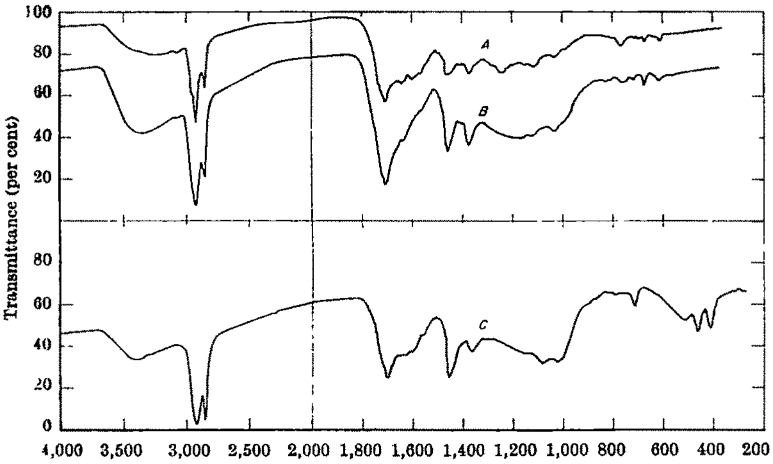

Fig 3 Infrared spectra of potassium bromide pellets curve *A*, pyridine extract of hard material, curve *B*, pyridine extract of soft material, curve *C*, kerogen concentrate from oil shale

sample For the hard material only the very intense absorption bands of the carbonaceous material were observable

Mass spectra of the rocks and of their pyridine extracts were obtained, but they were not informative Mass peaks of nearly equal intensity were observed at all masses investigated

The organic material obtained from the Puerto Rico Trench seems to be more nearly similar to kerogen from oil shale than to petroleum or coal This conclusion is based on the infrared spectra of both the extracts and the original carbonaceous rocks Neither petroleum nor coals possess intense absorption bands at the carbonyl position, 1,700 cm^{-1}, which are shown by the spectra of the ocean samples and the kerogen concentrate The highly aliphatic character of the ocean samples and the kerogen also differs from the more aromatic character of petroleum and coals The material is in a highly oxidized state, as shown by the oxygen contents and the intense OH and C=O bands in the infrared spectrum There does not seem to be any large amount of oxygen in ether type or heterocyclic structures according to the infrared spectra Two surprising findings are (1) there are many methyl groups or $-SO_2-$ groups or both, and (2) there is no indication in the infrared spectrum of the absorption characteristic of long, unbranched chains; the typical spectral band at 720 cm^{-1} does not appear The 1,375 cm^{-1} band in the spectra of carbonaceous materials is usually assigned exclusively to $-CH_3$ groups For curves *A* and *B*, however, the assignment is questionable because the 1,375 cm^{-1} band is unusually strong relative to the $-CH_2-$ band at 1,460 cm^{-1} The band shoulder at 2,950 cm^{-1} partly substantiates the assignment of 1,375 cm^{-1} to $-CH_3$ groups But, because of the presence of appreciable concentrations of sulphur and oxygen, plus the spectral indication of many oxygenated groups, it is believed that the 1,375 cm^{-1} band is partly produced by $-SO_3-$ groups

	Ocean	Kerogen
Aromatic CH	Greater	
CH_3 groups (or $-SO_2-$ groups or both)	Greater	
Long alkyl chains		Greater
OH	Greater	
Aromatics	Greater	

The infrared spectrum (Fig 3) of the soft material curve *B*, resembles somewhat the infrared spectrum of a kerogen concentrate from oil shale, curve *C* This resemblance, however, cannot be considered definitive The infrared absorption bands of both substances are too broad and ill-defined to be considered as proof of structure There are distinct differences between the spectra of the ocean samples and those of the kerogen concentrate, comparison of the spectra shows the chemical entities that predominate in the spectra of the ocean and kerogen materials

When the visible spectra of the ocean samples were compared with spectra of porphyrins, chlorins, bile pigments, and the metal complexes of these, the substance found to have a spectrum most similar to those of the ocean samples is pheophytin *a*[5], a chlorin which is a well known degradation product of chlorophyll *a* formed by the simple loss of magnesium This indicates that the organic material in the ocean samples is closely related to degradation products of plants, rather than of animals The discovery of a high magnesium content in the soft material (Table 1) tends to substantiate the close relationship of the organic portion to chlorophyll *a*

Trend in the Harmonic Energies of the Diurnal Variation at Two British Observatories

SEVERAL workers, the earliest of whom seems to be Schuster[1], have extensively analysed the world-wide distribution of the daily magnetic field variation, in order to obtain estimates of crustal electrical conduc-

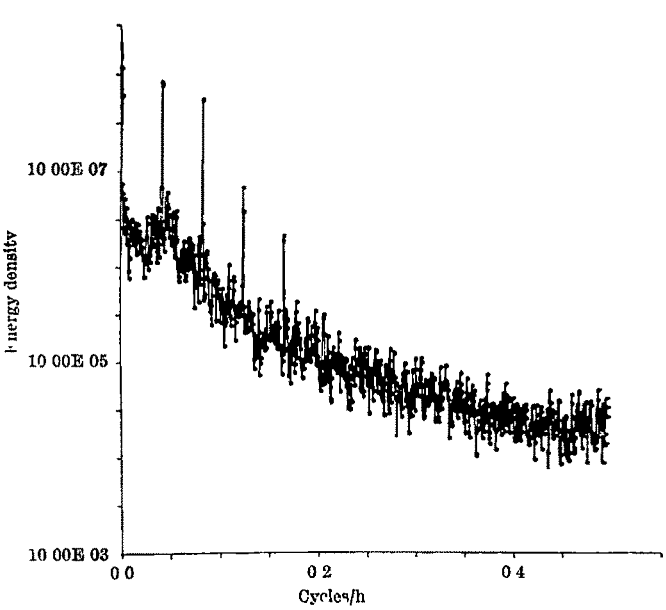

Fig 1 A spectrum of energy for variations in the vertical magnetic field for Eskdalemuir The peaks for 24 12, 8 and 6 h can be seen clearly

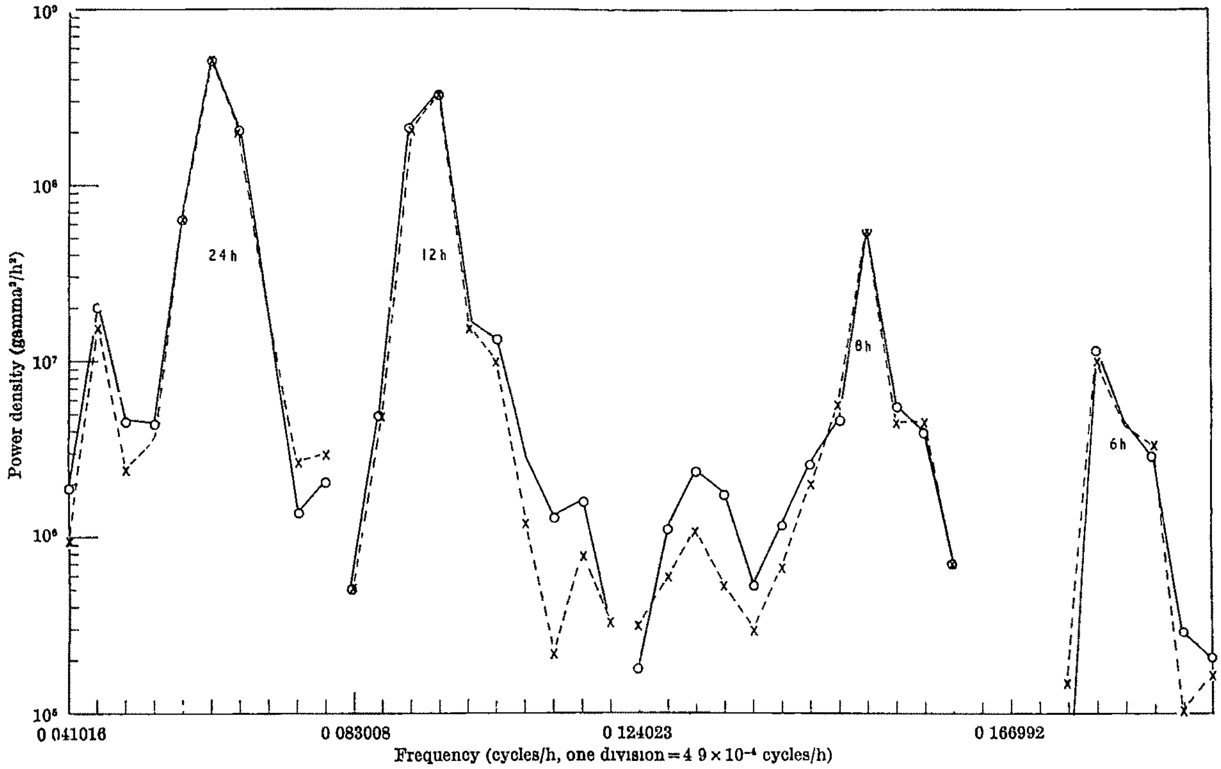

Fig. 2 The shape of the 24, 12, 8 and 6 h peaks in Fig 1 at full spectral resolution ———, Eskdalemuir, - - - - , Stonyhurst

tivity Much of this work was done before the advent of high speed computers, and may have been affected by subjective errors. The object of this communication is to present the results obtained by a full Fourier analysis of a year's data from two British observatories Comparison of these allows the errors in amplitude and phase of the spectral peaks to be estimated

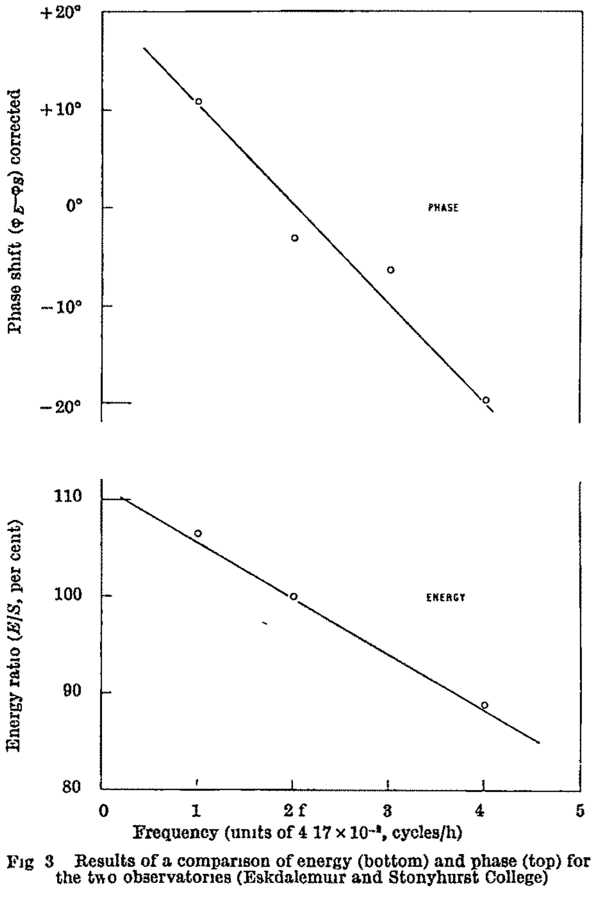

Fig 3 Results of a comparison of energy (bottom) and phase (top) for the two observatories (Eskdalemuir and Stonyhurst College)

The year 1964 was chosen as the most recent for which results are readily available The values used were (J D Jacobs and Father V E Worthy, private communications) measured at Eskdalemuir (lat 55° 19′ N , long 356° 48′ E) and at Stonyhurst College (lat 53° 51′ N , long 357° 32′ E) which are separated by 200 km along a line running N N E Both are removed from the coast, and so should be free from tidally generated fields The data used were the hourly values of the vertical field variation, and all the values taken during a year were used except for those on the disturbed days This gave a total of 7,344 hourly values A Fourier transform programme due to A Douglas (private communication) was used, and this gave estimates of energy and phase at frequency intervals of 1 22 x 10⁻⁴ cycles/h A smoothed spectrum is shown in Fig 1, the only lines which are clearly distinguishable from noise are those at periods of 24, 12, 8 and 6 hours The shape of these lines at the full spectral resolution is shown in Fig 2 It is apparent that there is good agreement between the estimated component energies, so that a detailed comparison between the two observatories should be meaningful The results of this comparison, in energy and in phase, are shown in Fig 3, where a correction has been applied to the phase estimates to allow for the 0 7° West relative longitude of Eskdalemuir

The first point about this comparison is the good consistency obtained .This is particularly striking in the case of the phase The phase zero for each frequency occurs at the time of the first reading each year and the individual phase estimates vary rapidly between ± 180° despite this the differences between the phases at the observatories are small and vary regularly It is estimated that the relative standard deviation of the estimates at the peak energies is ± 1 4 per cent in energy, ± 1 2° in phase

Riddihough[2] has shown that the variation with 24 h period in 1957 was higher at Eskdalemuir than at Stonyhurst, and the present work confirms this It is interesting that this difference falls to nothing for the 12 h variation and becomes negative at shorter periods Although the effect of oceanic edge currents would be expected to be of shorter range at shorter periods, this would not give a negative gradient in variation energy, it would only reduce the excess at Eskdalemuir The effect might be caused by the presence of a more highly conducting region beneath Eskdalemuir, which would reduce the coastal energy enhancement at all periods

PHYSICS

Circulation within Monolayer Films on Aqueous Substrates at Low Surface Pressures

ALTHOUGH at high surface pressures, up to about 20 dynes/cm^2, films of long chain fatty acids on water form uniform monolayers, at zero surface pressure the film is no longer uniform but has been described by some authors as consisting of "islands" held together by the van der Waals forces of cohesion between the hydrocarbon chains[1] An examination with an electron microscope of surface films of stearic acid prepared at a surface pressure of 3 dynes/cm^2 has provided some evidence that these irregularly shaped islands exist[2]

Radio-tracer studies of oleic acid and other films on water have revealed an interesting phenomenon lending credence to the existence of islands An apparent circulation of large film elements in a regular periodic manner has been observed Although oleic acid is usually considered to be "insoluble" in water, surface films after spreading to a pressure of 5–20 dynes/cm^2 do proceed to dissolve at a rate which is a function of the surface concentration As the diffusion process continues the surface pressure drops substantially and radioactive counting of the remaining surface film gave the results shown in Fig 1

The experiments were conducted as follows A 'Pyrex' glass dish 9 cm in diameter was cleaned and placed in a polyethylene holder Distilled water (50 ml) was then added to give a water depth of 0 8 cm A Baird–Atom model 821*B* counting tube, 3 cm in diameter, was placed over the dish, and the background radioactivity counted for 1 h in 10 min intervals The entire apparatus was suspended on a heavy steel plate attached by springs to a frame in order to block out vibrations Finally, a measured amount of radioactive oleic acid in hexane was spread on the water surface with an Alga micrometer syringe The counting rate was monitored for 24 to 170 h

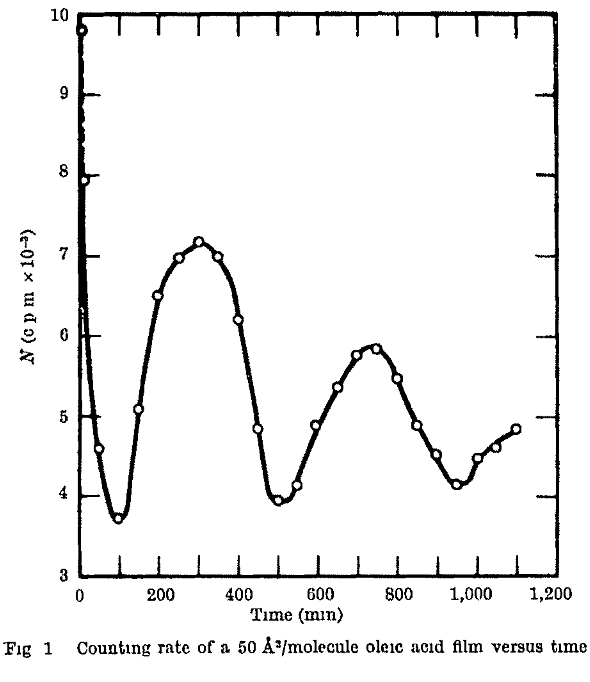

Fig 1 Counting rate of a 50 Å^2/molecule oleic acid film versus time

In many of the experiments, such as that shown in Fig 1, an oscillatory character was discovered in the counting rate The oscillations were attributed to an instability in the system termed the Marangoni effect[3] As the surface film diffuses into the water, the film remaining on the surface begins to form islands, a process which simultaneously gives rise to tension gradients engendered by the following mechanism

At equilibrium there would be islands but no surface tension gradients, because the islands would be surrounded by surface active molecules and smaller islands acting more or less individually, but nevertheless present in sufficient numbers so as to maintain a constant surface pressure over the entire surface Thus at the start of the experiment we have a picture of islands amid a distribution of smaller film segments without surface tension gradients If we permit molecular transfer by diffusion from the surface into the bulk, then it is easy to picture a situation in which the loss of a few molecules from an island into bulk will have little effect on the local surface pressure whereas the diffusion into the bulk of some of the individually acting molecules will result in a local increase in the surface tension, thus inducing a gradient Indeed, it is our opinion that the diffusion from the surface into the bulk of surface active material existing as a configuration of islands surrounded by molecules will be inherently unstable and always exhibit the Marangoni effect

Transport Processes and the Chemical Potential

MELEHY[1,2] has proposed a theory of transport phenomena, based on a claim that the chemical potential for each constituent is not a constant everywhere in a system which is in thermodynamic equilibrium He argues that the usual proof of its constancy everywhere is invalid, and that, in any case, its consequences are contrary to experiment For example he states[1] that the net work in transferring a particle between two points, whatever the gravitational or electrostatic potential difference may be, would be zero on the usual theory, that is, the transfer would be at constant energy Some consequences would be the denial of the existence of such effects as the Peltier effect and the necessity in thermal equilibrium for the conduction bands to line up throughout a crystal containing a non-degenerate p–n junction

I criticized[3] his theory, using a new method to validate again the constancy of the chemical potential, $\mu_i+\varphi$, throughout a system at thermodynamic equilibrium, μ_i

being the intrinsic chemical potential and φ the potential energy per unit mass of the long range gravitational or electrostatic forces I also showed that, in considering the work done in transferring a particle from one point A in the system to another point B, Melehy had neglected the contribution to the work done in changing the volume occupied by the particle from that at A to that at B

In a further communication[4], Melehy has applied his theory to obtain a formula for the current–voltage relation at a *p–n* junction His formula undoubtedly gives good agreement with the experimental results quoted. His reply to my criticism of his theories however, consists of the statement that his theory does account for the work contribution mentioned earlier He gives two reasons for this, the first that it is accounted for in the "subtle arguments" used in developing his theory, the second that his formula gives good agreement with the experimental results used Both reasons clearly do not assist scientific discussion, especially as in his arguments he postulates an expression for the diffusion force (see equation (28) of ref 1)

No comment is made on my defence of the constancy of the chemical potential at equilibrium, which is basically important because his theory is explicitly based on a contradiction of this well known result

In section (6) of ref 2 the following statement is made "The conclusion that $d\mu \neq 0$ whenever $dP \neq 0$ in the two preceding examples is an inevitable consequence of equation (16)

$$\{d\mu = -s dT + (1/n) dP\}$$

It might be of historical interest to state that the example of an atmosphere in thermal equilibrium happens to have been treated by Gibbs[21], who also has concluded that for that case $d\mu \neq 0$ in thermal equilibrium Clearly, it may now be stated that, under thermal equilibrium conditions, $d\mu$ will never vanish in any system wherever $dP \neq 0$, that is wherever $dn \neq 0$ "

On further study of ref 2, and taking into account especially this passage and the two examples cited, it is certain that the principal error has been a confusion between what Gibbs[5] called the intrinsic chemical potential and the chemical potential of a system under long range forces, which, for electric forces, is known as the electro-chemical potential It is, of course, well known that this latter quantity $\mu_i + \varphi$ is a constant everywhere at equilibrium and that its constancy determines the lining up of Fermi-levels It is also well known (see, for example, ref 3) that in a quasi-static isothermal displacement $\delta \mathbf{r}$ of a mass element m the work done is

$$\begin{aligned} \delta W &= \delta \mathbf{r} \, \{\nabla(Pv) + \nabla\varphi\} m \\ &= \delta \mathbf{r} \, \{\nabla(Pv) - \nabla\mu_i\} m \\ &= -m \delta \mathbf{r} \, \nabla f_i \qquad (1) \end{aligned}$$

where μ_i, f_i are the intrinsic chemical potential and intrinsic Helmholtz free energy per unit mass

Thus at equilibrium

$$\nabla\mu_i = -\nabla\varphi \qquad (2)$$

and $-\nabla\mu_i$ may in some way be regarded as a fictional force balancing that caused by the long-range forces The work done in a quasi-static isothermal displacement however, is not solely that arising from these forces but is given by (1) If ∇f_i is regarded also as a fictional force it is, of course, irrotational

A further confusion occurs in section (8) of ref 2 concerning the thermodynamic pressure and the pressure obtained from the Virial theorem in liquids and vapours It is claimed that in liquids if P is calculated by the Virial theorem it could be magnitudes higher than in the vapour This is wrong, as reference to any good text (for example, Hirschfelder, Curtiss and Bird[6]) on liquid theory would show, in fact the pressures according to either kinetic theory or thermodynamics are the same and this does not conflict, as implied, with the fact that, in the classical case, Maxwell–Boltzmann statistics applied

The agreement with experiment of the formula obtained by Melehy for the current–voltage relation of a *p–n* junction is interesting and this communication is written in the hope that a valid explanation may be made of the new terms introduced in the formula

CHEMISTRY

Simplification of the Synthesis of Tetramethyldipicrylamine

BECAUSE the antibacterial agent, tetramethyldipicrylamine, which we reported recently[1] has aroused wide interest we have developed a modification in the synthesis of the intermediate, 3,3′,5,5′-tetramethyldiphenylamine, which will make it possible for research workers to prepare experimental quantities of pure material in good yield without the necessity of elaborate equipment The methods reported previously involved heating 3,5-dimethylaniline and its hydrochloride in either a glass[2] or metal[3] autoclave at 235°–250° C or heating a mixture of 3,5-dimethylaniline and 3,5-dimethylphenol at 300°–400° C under 50 to 300 atmospheres pressure[4]

It was found that a sealed tube reaction was feasible when a slurry of equal amounts of 3,5-dimethylaniline and its hydrochloride, not exceeding a total of 7 g, was packed into a glass tube by means of a glass wool plug The tube, selected to have a volume of 3 ml /g of material, was sealed and heated in a constant temperature oven for 72 h at 230°–240° C A 74 per cent yield of good quality 3,3′,5,5′-tetramethyldiphenylamine was obtained This was washed with warm 7 per cent hydrochloric acid, extracted with either benzene or ether, dried over anhydrous sodium sulphate and nitrated without further purification to give a 72 per cent yield of the antibacterial agent, tetramethyldipicrylamine, melting point 232° C dec , reported 231° C dec We have extended the use of this simplified sealed tube method to the synthesis of 3,3′-dimethyldiphenylamine in 64 per cent yield and to 3,3′ *bis*- and 3,3′,5,5′-*tetrakis*-trifluoromethyldiphenylamine in lesser yields

BIOCHEMISTRY

Action of Atomic Hydrogen on Aqueous Bacteriophage T_7

WE have examined the action of hydrogen atoms on bacteriophage T_7 in aqueous suspension, and found the mechanism of inactivation to be premature release of the DNA.

The experimental procedure for treating with hydrogen atoms, using simple compounds and enzymes, was described earlier[1-6]. Hydrogen atoms produced in a 30 Mcs electrodeless discharge in pure hydrogen gas at 27 mm of mercury were swept through the solution at 4° C. The hydrogen gas flow of about 50 l./min excluded oxygen from all experiments. Control experiments showed that bubbling hydrogen alone did not produce significant effects.

The dose rate of hydrogen atoms, of about $1·5 \times 10^{-4}$ moles/l. min, was exactly determined before and after each experiment using the ferricyanide dosimeter[7,8].

Bacteriophage are more sensitive to ionizing radiation when they are in dilute aqueous suspension than when protected by gelatine or broth from the action of radicals formed in the water[9]. The protective action of oxygen in these conditions suggests that the reducing species produced in water may be responsible for bacteriophage inactivation[10], and preliminary experiments by Shapira and Stein on the effect of hydrogen atoms on phage T_7 indicates that this is so.

We used bacteriophage T_7 because Freifelder[13] has already shown that the DNA extracted from this phage has an extremely uniform sedimentation coefficient. Damage to the DNA can easily be measured with an analytical ultracentrifuge.

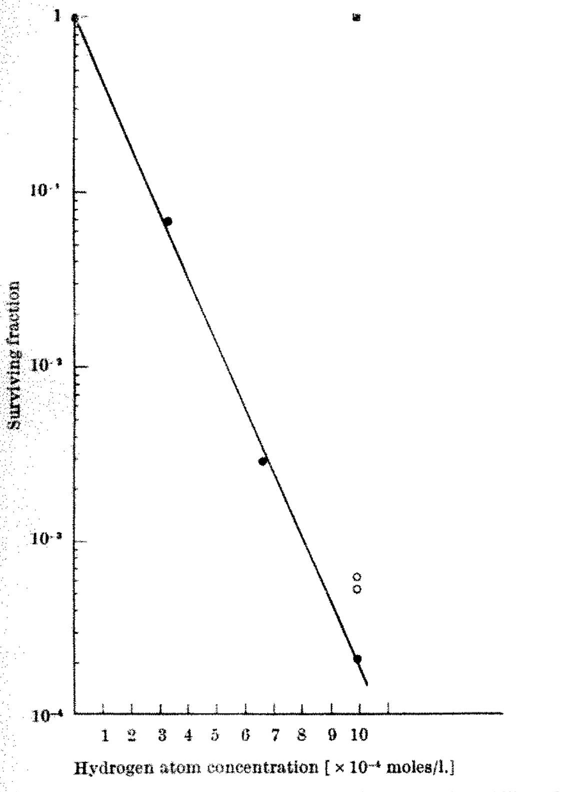

Fig. 1. The effect of hydrogen atoms on the plaque forming ability of phage T_7. Solid circles indicate the survival of phage suspensions given successive small doses of hydrogen atoms. Two large single doses are represented by hollow circles. The fact that these are above the line may be caused by small droplets thrown from the suspension by the gas bubbling and not falling back till after the irradiation. The lack of effect on phage in 1 per cent nutrient broth is indicated by the solid square.

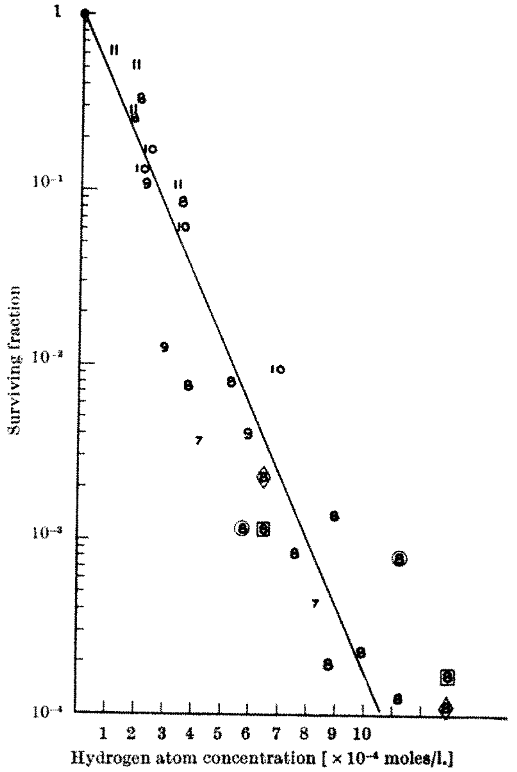

Fig. 2. Phage T_7 at various concentrations treated with hydrogen atoms. The numbers are the log concentration of phage/ml. For example, 8 represents the surviving fraction after treating a phage suspension containing 10^8 phage/ml. The enclosed numbers refer to treatment of the phage in the presence of added magnesium sulphate. ○, 10^{-4} Molar magnesiun. □, 10^{-3} molar magnesium; ◇, 2×10^{-2} molar magnesium. The line is taken from Fig. 1.

The experimental details of growing, purifying and assaying the phage on *E. coli B* have been described[11,12]. The bacterial debris was removed by centrifugation at 4,000*g* for 10 min. Phage was recovered by treatment at 75,000*g* for 2 h; the caesium chloride buoyant density purification procedure was carried out at 150,000*g* for 14 h.

Figs. 1 and 2 show the effects of atomic hydrogen on T_7 at various concentrations with and without 1 per cent broth and with and without various concentrations of added magnesium ions. It will be seen that phage T_7 in 0·01 molar phosphate buffer at *p*H 7·8 and 0·1 molar NaCl was inactivated in triple distilled water by atomic hydrogen with a strict exponential relationship between survival and dose. The results in Figs. 1 and 2 show clearly that there is no initial shoulder which has sometimes been observed with X-rays by others[13]. The absence of a shoulder is consistent with a mechanism of inactivation which involves only one crucial event per phage. This does not exclude the possibility that some of the hydrogen atoms reacted at a number of inessential sites on the phage.

The almost complete protection by broth (Fig. 1) is consistent with competition for the available atomic hydrogen. In our system, hydrogen atoms are introduced into the liquid from the gas phase and their reaction with phage (Ph) competes with their reactions with other substrates (S), and also with the recombination of hydrogen atoms

$$H\cdot + Ph \rightarrow HPh\cdot \rightarrow \text{unknown products}$$
$$H\cdot + S \rightarrow HS\cdot \rightarrow \text{unknown products}$$
$$H\cdot + H\cdot \rightarrow H_2$$

As shown in Fig. 2, the D_0 for the loss of plaque-forming ability is about $1·2 \times 10^{-4}$ moles of hydrogen atoms/l., and is independent of phage concentration between 10^7 and 10^{10} phage/ml., with possibly a very slight increase at 10^{11} phage/ml. We considered three

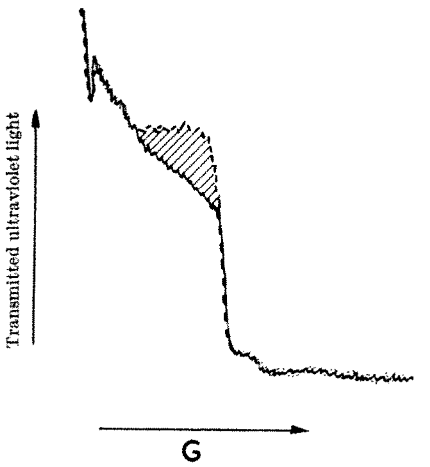

Fig. 3. Tracings of the ultraviolet absorption patterns of the DNA from phage T_7 in an analytical ultracentrifuge. The control DNA (dotted line) has been superimposed on the DNA from phage treated with hydrogen atoms (solid line) after suitable adjustment of magnification to allow for differences in concentration and differences in film development. The shaded area shows where the two lines diverge because of the slower sedimentation rate of some of the broken DNA released from phage treated with hydrogen atoms.

possible mechanisms of action of hydrogen atoms on phage. (*a*) Damage to the DNA. This assumes that atomic hydrogen penetrates the protein coat or that one electron equivalent is transferred to DNA from the protein after hydrogen atoms have been added to the protein coat. (*b*) Bond formation between protein and DNA. This might prevent efficient injection of DNA into the host bacterium. (*c*) Action on the protein coat only. This might either inhibit the injection mechanism or cause premature release of DNA in the absence of a host bacterium.

To distinguish between these possibilities we studied the sedimentation patterns of the DNA from T_7, using an ultracentrifuge. Phage T_7 was induced to release its DNA by heat treatment in the presence of 0·001 molar EDTA (ref. 14). Very sharp Schlieren boundaries were obtained and the microdensitometer traces of ultraviolet absorption photographs also indicated a single sharp moving boundary consistent with the presence of only one component.

By spinning down the sample which had been treated with hydrogen atoms and which had not received the heat release treatment, we found indications that material had been released from the phage. A very diffuse Schlieren picture was obtained, and the microdensitometer traces of the ultraviolet photographs were consistent with an inhomogeneous population of smaller molecular weight fragments, which might have resulted from the breaking up of released DNA. Finally, when samples which had been treated with hydrogen atoms were also heat-released in the absence of magnesium ions (to release any DNA still retained within the protein coat) a mixed population was obtained in the ultraviolet microdensitometer trace, indicating the presence of both intact and broken DNA. The ratio between intact T_7 DNA and broken fragments was approximately the same as that between surviving and inactivated T_7 in the particular treated sample (Fig. 3).

Further evidence to suggest a mechanism of DNA release actuated by hydrogen atoms was obtained by studying electron microscope photographs of untreated and hydrogen atom treated T_7 phage. The results, shown in Fig. 4, are consistent with the view that after treatment with hydrogen atoms we are observing hollow shells of the protein coat, from which DNA has been ejected into the solution in the absence of bacteria.

To correlate our results with the effect of ionizing radiations in similar conditions of water purity and absence of competing scavengers, we examined the action of caesium-137 gamma rays on T_7 phage. If gelatine or broth is present to remove the effects of radicals formed in the water by ionizing radiation, high doses are needed to inactivate phage T_7 (ref. 13). At the low doses used in these experiments the direct target type action is negligible. The results are shown in Fig. 5. The D_0 for the 0·6 MeV gamma rays is about 500 rad. Thus in our experimental conditions the sensitivity to radiation is higher than previous data in the literature[13]. For the radiation experiments, too, the strict exponential relationship holds and there is no shoulder.

The calculation of reaction velocities and rate constants of a very large molecule, such as T_7 phage, with hydrogen atoms in our experimental conditions cannot be justified, because of the many assumptions required. Qualitatively, however, the number of radicals needed to inactivate phage irradiated with gamma rays and with hydrogen atoms, respectively, are comparable, when allowance is made for the non-homogeneous kinetics in the case of hydrogen atoms[1].

There is a slow spontaneous release of DNA from phage T_7 which is prevented by the presence of magnesium ions[11]. To see whether the only action of hydrogen atoms is to speed up the rate of spontaneous release, we examined the effect of added magnesium ions on the effectiveness of hydrogen atoms. There was no effect of added magnesium, as Fig. 2 shows. Thus the role of hydrogen atoms in inactivating phage T_7 is not connected directly with magnesium ions as a stabilizing factor, although it may have to do with that part of the protein responsible for the binding of magnesium.

To determine the sensitivity of *E. coli* bacteria to treatment with hydrogen atoms, compared with the sensitivity of phage T_7, bacteria grown on Difco nutrient broth were twice centrifuged, washed with triple distilled water, and brought to a concentration of 10^5 bacteria/ml., in 0·01 molar phosphate buffer at *p*H 6·8. A dose of 6×10^{-4} moles/l. of hydrogen atoms gave no measurable effect. The same dose reduces phage T_7 to less than 1 per cent of its original value. This shows that phage may be selectively inactivated by a method which has almost no effect on *E. coli*.

Hydrogen atoms act in the systems now investigated

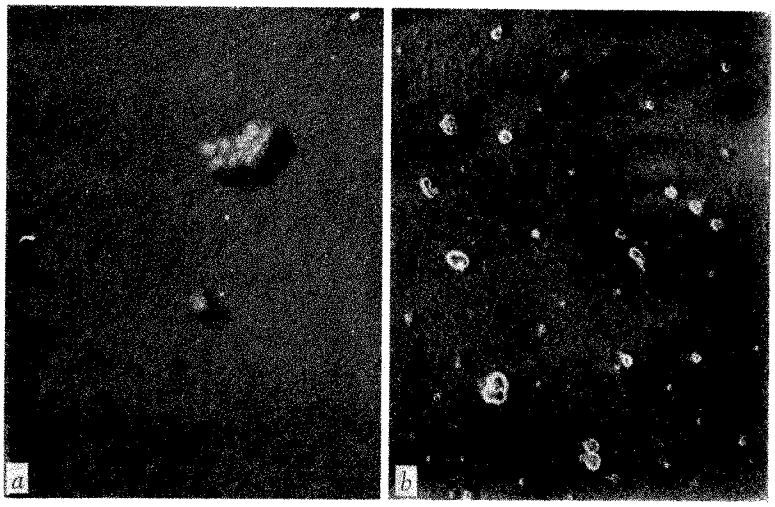

Fig. 4. Photographs of uranium shadowed phage T_7 taken on an RCA electron microscope at 100 kV. (× 47,600.) *a*, Control untreated phage; *b*, after treatment with hydrogen atoms ($3{\cdot}6 \times 10^{-4}$ moles/l.).

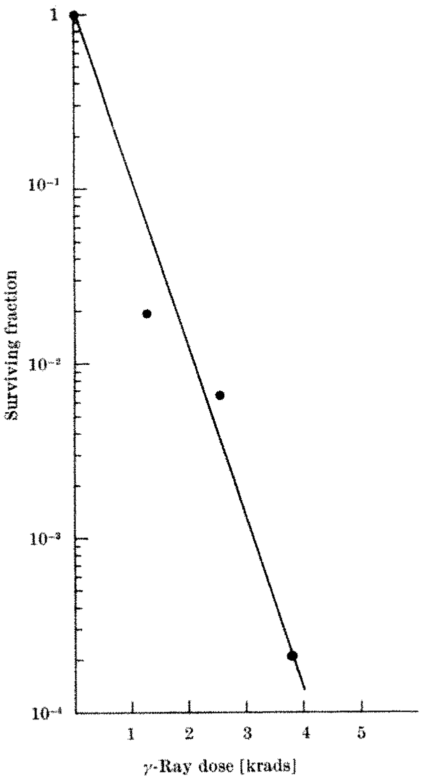

Fig. 5. Inactivation of phage T_7 by caesium-137 gamma rays. The phage were diluted to 10^8/ml. in phosphate buffer *p*H 7·8 using the same triple distilled water as was used for the hydrogen atom experiments. The samples were saturated with hydrogen gas before irradiation.

as simple one electron equivalent reagents. Other one electron equivalent chemical reagents as well as electrolytic reduction may be expected to behave in the same way. An advantage of hydrogen atom treatment is that at the end of the experiment no additional chemical other than inert hydrogen gas remains in the system.

Gene Conversion: Temperature Data from *Sordaria fimicola* on the Correction of Mis-paired Bases

CORRECTION of mis-paired bases in hybrid DNA is a basic postulate of current models of gene conversion and recombination[1-5]. Although some models invoke different origins of hybrid DNA, they involve similar repair processes. At each heterozygous site in a region of hybrid DNA, there are three possibilities: repair to wild type, repair to mutant and non-repair.

The temperature dependence of correction processes in gene conversion has been studied by obtaining data relating to these possibilities from visual scoring of asci with different ratios of wild type (+) to mutant (*m*) spores in crosses of the ascospore-pigmentation mutants grey (*g*) and hyaline (*h*) in *Sordaria fimicola*. These mutants were crossed with their respective wild types at different temperatures, at 2·5° C intervals, for the range 10°–31° C, using methods already described[6]. To test for phenocopies as a cause of apparent conversion, spores were isolated from crosses made at 10° C, 20° C and 30° C: *h* spores were inviable but none of about 200 *g*, g^+ and h^+ spores which germinated to produce fertile colonies were phenocopies. Large changes in total conversion frequency with temperature were observed but will be discussed elsewhere, for they are not directly relevant to the correction data.

Effects of temperature on the direction of correction (that is, whether correction is to wild type or to mutant) were determined from the observed frequencies of correction to wild type (one such event in 5+ : 3 *m* asci and two in 6+ : 2 *m* asci) and of correction to mutant (one such event in 3+ : 5 *m* asci, two in 2+ : 6 *m* asci). The relative frequencies of these two kinds of correction did not change significantly at any of the temperatures used for either locus, although the ratio differed for each locus (Table 1). The constancy of these relative frequencies indicates that the direction of correction of mis-pairing is independent of temperature. If there is one enzyme that can excise a base from any of the eight possible pairs of mis-paired bases, this evidence would suggest that the affinity of the excising enzyme for one base rather than another is unchanged by temperature; this applies both to conversion at the hyaline site, where correction in either direction was equally frequent (heterogeneity $\chi^2_1 = 0{\cdot}4$, $P = 0{\cdot}5$–$0{\cdot}7$), and to the grey site, where a preferential correction to wild type was found ($\chi^2_1 = 12{\cdot}5$, $P < 0{\cdot}01$). Alternatively, if there is more than one enzyme, each excising different bases, then the present data indicate that their relative effectivenesses—which would depend on their relative concentrations, rates of action and affinities—are unaffected by temperature. The one enzyme hypothesis seems more probable than the multienzyme hypothesis because the former requires fewer variables to be independent of temperature.

Table 1. EFFECT OF TEMPERATURE ON RATIOS OF ABERRANT ASCI IN CROSSES OF *Sordaria fimicola*

* The same trend is shown if this value is calculated separately for 5 : 3 and for 6 : 2 asci.

There are three frequencies pertinent to the efficiency of correction: that of no correction (giving post-meiotic segregation in 4 : 4 asci), that of correction in one chromatid (giving 5 : 3 asci) and that of correction in both chromatids (giving 4 : 4 and 6 : 2 asci). Post-meiotic segregation was not distinguishable from spindle overlap at the third division in the ascus, so the first of these frequencies could not be determined. The 4 : 4 class from correction in both chromatids is not distinguishable from other 4 : 4 asci, so the 6 : 2 class can only be used here as a measure of correction in both chromatids if the proportions of 6 : 2 and 4 : 4 asci from correction did not vary with temperature. If the direction of correction is independent in both chromatids, these proportions will depend solely on the relative frequencies of correction to wild type and to mutant, which were here independent of temperature. Changes in the relative frequencies of 6 : 2 and 5 : 3 ratios can therefore be used as a measure of changes in the relative frequencies of correction in both chromatids, or in only one chromatid, respectively. For the grey locus, no consistent change with temperature was observed for this value (Table 1) but at the hyaline locus it was highest over the range 17·5°–22·5° C and lowest at the two temperature extremes. Although the data are not heterogeneous as a whole for this value ($\chi^2_5 = 4{\cdot}9$, $P = 0{\cdot}8$–$0{\cdot}9$ for hyaline, $\chi^2_5 = 5{\cdot}0$, $P = 0{\cdot}7$–$0{\cdot}8$ for grey), hyaline values at high temperatures are significantly different from those at medium temperatures ($\chi^2_1 = 4{\cdot}0$, $P = 0{\cdot}02$–$0{\cdot}05$ for pooled values at 30° and 31° C versus pooled values for 17·5°, 20° and 22·5° C). These results suggest that correction at the hyaline site is impaired at extreme temperatures but a similar trend was not found for the grey site. The difference observed between loci could possibly result from the different genetic backgrounds in the two sets of crosses, or perhaps correction is not independent in both chromatids.

Another difference between conversion at the two sites is that for grey 5 : 3 asci are significantly more frequent than 6 : 2 asci ($\chi^2_1 = 5{\cdot}7$, $P = 0{\cdot}01$–$0{\cdot}02$), while the reverse is true for hyaline ($\chi^2_1 = 33{\cdot}4$, $P < 0{\cdot}01$). If allowance is made for undetected conversion resulting in asci with 4+ : 4 *m* ratios, correction in both chromatids is more frequent than correction in only one chromatid for grey as well as for hyaline, but the difference between the two sites in the relative frequency of the two kinds of correction becomes still greater. This suggests that correction is more efficient at the hyaline site than the grey site. Allowance for this undetected reciprocal conversion class would also result in values closer to unity for the ratio of correction to + : correction to *m*.

From these studies it is concluded that the direction of correction of base mis-pairing is independent of temperature; in other respects, different trends were observed for conversion at the grey and at the hyaline sites. These differences may result from different bases being mis-paired in hybrid DNA at each site but other explanations are possible.

Indospicine, a New Hepatotoxic Amino-acid from *Indigofera spicata*

Indigofera spicata Forsk (previously *I. endecaphylla* Jacq.) would be a useful tropical pasture legume without its toxic properties (for review, see ref. 1). It has been shown to be hepatotoxic to sheep, cows and rabbits, and has caused abortion in pregnant animals[2]. Hutton *et al.*[3,4] showed that the leaf and seed were hepatotoxic to rabbits and mice and that β-nitropropionic acid, which occurs only in the leaf, did not account for these liver lesions. Britten *et al.*[5] found that β-nitropropionic acid or a compound closely associated with it in the leaf was toxic to chicks, which were not affected by the hepatotoxin(s) present in the seed.

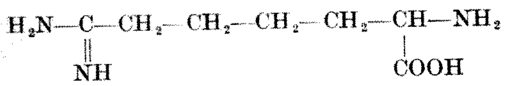
We report here the isolation from seed and leaf of a new amino-acid, designated indospicine, which produces characteristic liver lesions in mice. Indospicine is shown to be L-α-amino-ε-amidino caproic acid, corresponding to structure (I).

A rapid, semi-quantitative bioassay in mice was developed for testing the hepatotoxicity of the various extracts and fractions. It was based on the accumulation of fat in the liver produced by a single subcutaneous injection of a toxic aqueous extract of seed[6]. Further experiments were carried out in which groups of four female mice were injected with graded doses of the same extract and then killed at intervals. Frozen sections of the livers stained with sudan IV for fat were examined microscopically in random order and fat accumulation was graded from 0–4. Based on this method of grading, the maximum accumulation of fat occurred about 48 h after injection and was related to the amount of extract used. Repeated tests showed that the results were reproducible. This bioassay was then used to compare the hepatotoxicity of various extracts and fractions from extracts during the isolation

Earlier work[6] showed that the hepatotoxin behaved as a cation on ion-exchange resins, and further experiments indicated that the hepatotoxicity was associated with the strongly basic fraction of the seed. This fraction was isolated from the ground seed on a preparative scale by a modification of the adsorption-dialysis method[7,8] in which Zeokarb 226 (H) was used inside the dialysis tubes. The bases were eluted with 2 normal acetic acid and the extract concentrated to a small volume (1 ml. = 10 g of seed). Some of the bases present were tentatively identified by paper chromatography in several solvent systems and by the use of a wide range of detecting reagents[9]. Canavanine, arginine and several unidentified guanidino-compounds were present, but the principal ninhydrin-positive substance was an α-amino-acid with properties different from those of the known amino-acids. The ninhydrin-positive substances present in the extract were isolated by one-directional chromatography of aliquots of the extract (0·25 ml.) on 400 sheets of Whatman 3 MM paper. Isopropanol/2 normal hydrochloric acid (78 : 22 v/v) was used as the solvent. The various bands, located by ninhydrin treated test strips, were cut from each sheet; corresponding bands were bulked and extracted with water. The separate extracts were concentrated and excess hydrochloric acid was removed. Part of each extract was assayed for hepatotoxicity. The toxicity of the original extract was almost quantitatively located in one band which contained the new amino-acid, now named indospicine, and a small amount of arginine. Indospicine was isolated from the remainder of this extract as the sparingly soluble monoflavianate which, after repeated recrystallization from water, was converted to the hydrochloride which still contained a small amount of arginine. This was removed by ion-exchange chromatography[10]. Indospicine was also isolated from an aqueous extract of leaf by a modification of the method of Awapawa *et al.*[11]. The flavianate and hydrochloride were identical with the corresponding derivatives from seed.

Indospicine monohydrochloride crystallized from aqueous ethanol as white needle-like crystals of the monohydrate, melting point 131°–134° C, $(\alpha)_D^{22} + 18°$ in 5 normal hydrochloric acid (C, 1·1). (Found: C, 37·4; H, 8·1; N, 18·5; Cl, 16·0 per cent. Calculated for $C_7H_{15}O_2N_3.HCl.H_2O$: C, 37·0; H, 8·0; N, 18·5; Cl, 15·6 per cent). Analyses of the monoflavianate and monopicrate completely supported the empirical formula $C_7H_{15}O_2N_3$ for the free base. The picrate ion absorption at 380 mµ indicated a molecular weight of approximately 175 for indospicine. It gave a purple colour with ninhydrin on paper chromatograms and behaved as an α-amino-acid when treated successively with cupric acetate and ninhydrin. With the nitroprusside–alkaline ferricyanide reagent[9] it gave a yellow colour similar to that given by acetamidine and quite different from the red colours shown by mono-substituted guanidines. It moved as a positively charged ion on paper ionophoresis in the range *p*H 2–10·5 and decomposed at higher *p*Hs.

The free base, prepared by chromatography on a column of 'Dowex 2', was degraded to distilled water at 120° C or in 0·1 molar sodium carbonate at 40° C to ammonia (1 mole) and a neutral α-amino-acid $C_7H_{14}O_3N_2$. This compound was shown to be an amide by hydrolysis in 1 normal hydrochloric acid at 120° C to ammonia (1 mole) and L-α-amino-pimelic acid (APM). Indospicine was also degraded in 6 normal hydrochloric acid at 120° C to APM (1 mole) and ammonia (2 moles). APM and its amide were identified by melting point, optical rotation, elemental analysis, infrared, nuclear magnetic resonance and mass spectra. The chemical and spectroscopic evidence is in agreement with formula (I) for indospicine.



$$H_2N-\underset{\underset{NH}{\|}}{C}-CH_2-CH_2-CH_2-CH_2-\underset{\underset{COOH}{|}}{CH}-NH_2 \quad (I)$$

Indospicine hydrochloride produced liver lesions in mice identical with those produced by various crude extracts of the seed. Canavanine and arginine did not cause fat accumulation in the liver, nor did they interfere with the indospicine assay. Pearn[12] has recently demonstrated the presence of a new type of cleft palate teratogen in the same seed extract from which we isolated indospicine. The teratogenic activity of the extract is caused by indospicine (unpublished results of Pearn and Hegarty).

Indospicine is the first naturally occurring hepatotoxic amino-acid to be isolated. Compounds containing the simple amidine system have not previously been found in plants although the grouping occurs in the antibiotics congocidin and distamycin *A* (ref. 13).

Relative Binding of Strontium and Calcium in Protein and Non-protein Fractions of Serum in the Rabbit

WE have reported a discrimination between the ratio of strontium to calcium in rabbit plasma and that in bone[1]. We reasoned that this discrimination could be the result of a difference in this ratio in the protein and non-protein fractions of the plasma. If the ratio of strontium to calcium in the non-protein fractions was lower than that in the plasma as a whole, then the ratio in the extracellular fluid might be expected to be lower and hence account for the lower ratio which has been observed in bone. To test this hypothesis a double tracer experiment using strontium-85 and calcium-47 was carried out in two rabbits which were of the same strain and age (7 months) as those used before. The protein and non-protein fractions were separated in an ultracentrifuge and the ratio of strontium-85 to calcium-47 was determined for these fractions as well as for the whole serum. These measurements showed that the ratio was the same for all fractions within the limits of experimental error.

Two rabbits were injected intravenously with 30 µc./kg of calcium-45 and 85 µc./kg of strontium-85 into the marginal vein of the ear and killed 24 h later, when about 40 ml. of blood was collected from each animal after severing the jugular vein. The blood was allowed to clot and the serum decanted off. A sample of serum (10 ml.) was spun at about 200,000*g* (40,000 r.p.m.) in an ultracentrifuge[2] to separate the protein and non-protein. A thin layer of liquid paraffin was floated on top of the serum to prevent changes in *p*H during centrifugation, because changes in *p*H have been shown to alter the proportion of calcium bound to protein[3]. The non-protein component, which appeared clear at the top of the centrifuge tube, was removed with a syringe in two fractions, the first fraction being just below the layer of paraffin; the second fraction, the bottom of which was in contact with the protein, was removed separately to prevent mixing during transfer. The protein component, which was a gelatinous semi-solid (yellowish at the top and merging into a reddish-brown colour at the bottom), was also removed with a syringe into a counting dish for radioactive assay.

Strontium-85 and calcium-45 were assayed on the same sample using a scintillation counter with a sodium iodide crystal. The energy spectra for the two isotopes standards were run independently to determine the optimum conditions for distinguishing between them. The discriminator bias was set so that only pulses from calcium-47 were counted. Strontium-85 was counted using a single channel at a lower discrimination level; the counts in this channel caused by calcium-47 were subtracted. The amount of this isotope injected was chosen to be about one-third of the amount of strontium-85, thereby reducing the inter-

Table 1. STRONTIUM-85 AND CALCIUM-47 IN DIFFERENT FRACTIONS OF SERUM 24 h AFTER INJECTION

Sample		Strontium-85 (per cent injected dose/ml.)	Calcium-47 (per cent injected dose/ml.)	Strontium-85 : calcium-47
Whole serum	1623	$2\cdot30\times10^{-3}$	$5\cdot69\times10^{-3}$	0·41
	1624	$2\cdot70\times10^{-3}$	$6\cdot12\times10^{-3}$	0·44
Fraction I	1623	$1\cdot58\times10^{-3}$	$3\cdot82\times10^{-3}$	0·41
	1624	—	—	—
Fraction II	1623	$1\cdot73\times10^{-3}$	$4\cdot08\times10^{-3}$	0·42
	1624	$2\cdot10\times10^{-3}$	$4\cdot80\times10^{-3}$	0·44
Fraction III (protein)	1623	$3\cdot01\times10^{-3}$	$7\cdot25\times10^{-3}$	0·42
	1624	$3\cdot76\times10^{-3}$	$8\cdot02\times10^{-3}$	0·47

ference of the calcium isotope in this channel. All the samples used for measuring radioactivity were made up to a standard volume for counting.

The results for the different fractions of serum (Table 1) show that for rabbit 1623 the ratio of strontium-85 to calcium-47 is the same to within 3 per cent in the whole serum as in both the protein-bound and the protein-free fractions. In rabbit 1624 the ratio is somewhat greater but is the same for all fractions within experimental error. It is therefore clear that the previously reported[1] discrimination of 1·6 against strontium in the transfer between blood and bone cannot be attributed to the difference in the ratio of strontium to calcium between the protein-free plasma and the plasma as a whole.

The discrimination might be explained by the fact that the measurements were made of naturally occurring levels of the stable isotopes when the animals were in a state of equilibrium, rather than of the radioisotopes shortly after administration. Recent measurements made at longer intervals after administration suggest that there may be a difference between the relative behaviour of strontium and calcium soon after administration and after a longer interval.

Detection of Insulin Precipitating Antibodies

THERE are various immunological techniques for detecting antibodies to peptide antigens, but the detection of precipitating antibodies to small peptide hormones which are poor antigens may be difficult. Preparations of crystalline insulin from a variety of species are quite similar and only a few differences in amino-acid composition have been found, which in addition to the smaller molecular size may account for its poor antigenicity. Nevertheless, the Ouchterlony technique[1] has revealed precipitating antibodies to insulin (for example, refs. 2–5).

With guinea-pig insulin antisera, we were unable to see clear insulin–anti-insulin precipitates by the agar-gel immunoelectrophoretic technique[6,7] but have demonstrated several antigen–antibody precipitin lines by a modification of this procedure. A new immunological technique has been developed which involves (*a*) electrophoretic separation, (*b*) immunodiffusion and (*c*) exclusion of antigen–antibody complexes by the addition of the water-soluble polymer dextran.

Pork insulin (24 IU/1 mg) ten times recrystallized (gift from Novo) was used to immunize guinea-pigs. The hyperimmune sera obtained by cardiac puncture were a gift from Dr U. Lundkvist. Five different hyperimmune insulin antisera were tested and they gave identical results.

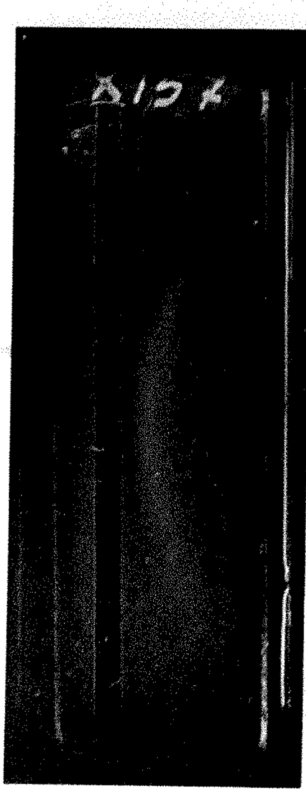

Fig. 1.

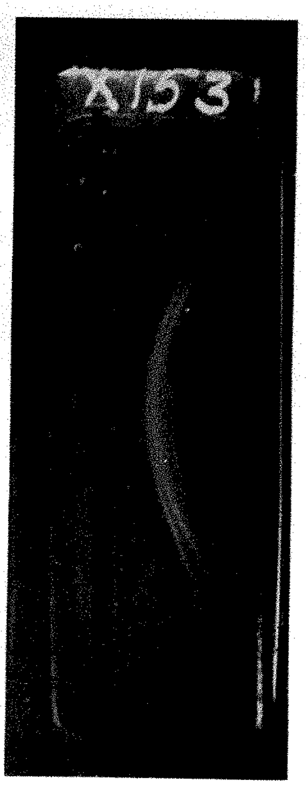

Fig. 2.

Fig. 1. Immunoelectrophoretic run of insulin and guinea-pig insulin antisera in agar medium. (Control experiment.)

Fig. 2. Immunoelectrophoretic run of insulin and guinea-pig insulin antisera in agar medium. (Infusion with dextran solution.)

Immunoelectrophoresis was carried out on microscope slides in LKB apparatus. The slides were coated with a 1·5 per cent agar solution (agar-noble, Difco) made up in veronal buffer (pH 8·6, ionic strength 0·03). The antiserum used was shown to contain insulin antibodies by the radioimmunoassay technique of Wide and Porath[8]. After antiserum had diffused into the agar gel, 'Dextran 10' (mean molecular weight 10,000, Pharmacia AB) was poured into the trough and allowed to diffuse (infusion procedure). The dextran used in these experiments was dissolved in a veronal buffer solution (pH 8·6 and ionic strength 0·1). The final concentration of 'Dextran 10' was 8 per cent (w/v).

The microscope slides were then placed in a moist chamber and incubated for 2 days at 37° C in an air-incubator. During incubation the dextran solution was placed three times (at equal time intervals) into troughs (altogether 0·75 ml. of 8 per cent 'Dextran 10' per slide or per 1·5 ml. of agar was added). After 2 days of incubation at 37° C, the slides were placed in a cold room at 4° C for 3 days.

After 13 h of incubation at 37° C, antigen–antibody precipitates could be seen in agar–dextran media, while in the control experiment (only agar) a very faint and broad, cloudy precipitate was just detectable. In agar–dextran medium a sharp and distinct precipitin line was seen on the side nearer the well, while the second precipitin line underneath (nearer the trough) was rather diffused, but easily seen. Both lines showed the same anodic movement. After 40 h of incubation at 37° C the precipitin bands sharpened and a new and sharp precipitin band appeared below the broad cloudy precipitate. After a further 3 days of incubation at 4° C, the immunoprecipitates were observed again and photographed. Results of the control experiment are shown in Fig. 1, while Fig. 2 shows the precipitin lines of antigen–antibody in agar medium which was infused with dextran solution.

The time sequence of the appearance of precipitin lines was as follows: first, the less diffusible antigen(s) precipitated out, while lastly the most diffusible antigen(s) formed a precipitate. Possibly the aggregated part of insulin, if any, was precipitated first, while the precipitin reaction between less aggregated insulin molecules and the antibody took longer.

It has been suggested[9-13] that polysaccharides may exclude some proteins from solution rather than interacting with them. Dextran seems to decrease the solubility of immuno-complexes in agar gel medium and helps to exclude them.

Occurrence of Haemocoelic Erythrocytes containing Haemoglobin in a Wood Boring Mollusc

DURING recent studies of the rock and wood boring molluscs of the super-family Adesmacea (Mollusca : Bivalvia) the occurrence of haemocoelic erythrocytes in the blood of *Xylophaga dorsalis* Turton was noticed while examining serial sections. The erythrocytes are slightly flattened disks of diameter $10–12\mu$, each containing a prominent nucleus (Fig. 1).

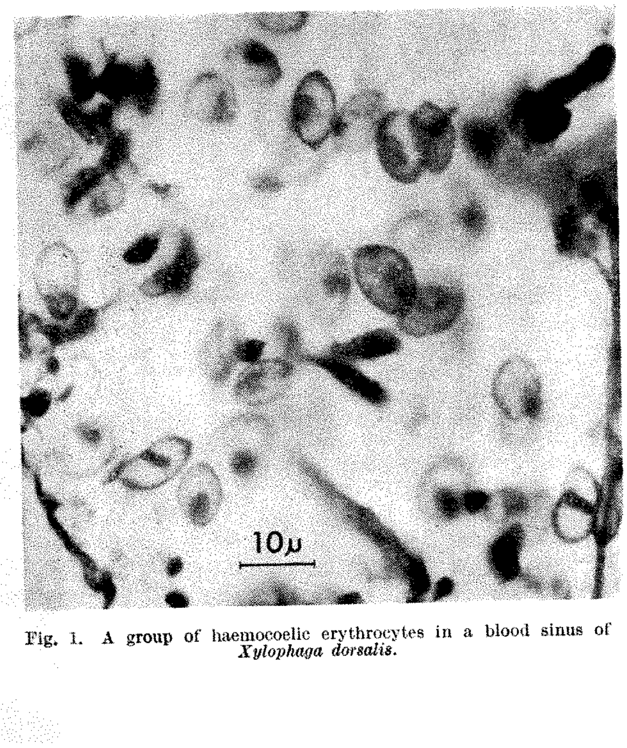

Fig. 1. A group of haemocoelic erythrocytes in a blood sinus of *Xylophaga dorsalis*.

The blood of this species possesses a light pinkish colour, and our observations suggest that this tint is a consequence of the presence of haemoglobin in the erythrocytes. Dried smears of the blood gave a positive result to the benzidine reaction[1] which stained only the erythrocytes dark blue, while a dilute solution of the pigment in distilled water showed a major absorption peak at 415 $m\mu$, and indications of α and β peaks at 578 $m\mu$ and 540 $m\mu$. Treatment with carbon monoxide caused a shift in the major absorption peak to 420 $m\mu$ and of the α peak to 568 $m\mu$. These changes are consistent with the transformation of oxy-haemoglobin to carboxy-haemoglobin and with previous knowledge of absorption spectra of molluscan haemoglobins[2], and are therefore taken as confirmation that the pigment in *Xylophaga* is a haemoglobin.

The possession of haemoglobin by a member of the Adesmacea has not been reported before, although myoglobin occurs in the adductor muscle of species of *Bankia* and *Teredo*[3]. The isolated instances of the occurrence of haemoglobin in solution in the haemolymph, in the ctenidium, and in haemocoelic erythrocytes elsewhere in the Bivalvia, have been reviewed recently[4]. Interpretation of the function of the haemoglobin of *Xylophaga*, a species which is usually found attacking submerged waterlogged timber[5], must await more detailed biochemical and physiological investigations of its properties.

This work was carried out during the tenure of a Royal Society and Nuffield Foundation Commonwealth bursary held by one of us (N. B. N.).

Specific Method for Estimating Cell Numbers in Tendons

STUDIES of growth, ageing and functional adaptation of dense regular connective tissue of tendons and ligaments are limited because of the lack of a simple accurate method for the estimation of the cell populations involved[1]. Standard histometric techniques for cell counting are especially difficult to apply to tough intractable, fibrous tissues, and there is an obvious need for a simpler quantitative method which is accurate, reproducible and rapid.

If the amount of DNA in the somatic diploid cell nucleus is known, and if total tissue DNA can be extracted, cell numbers can be readily calculated, for it has been shown that the diploid amount of DNA in the cell nuclei is constant for a particular species[2]. This fact is the basis of a number of growth and cell population studies involving whole animals and tissues[3]. These methods have, however, never been applied to dense, fibrous, relatively acellular tissues such as tendons and ligaments.

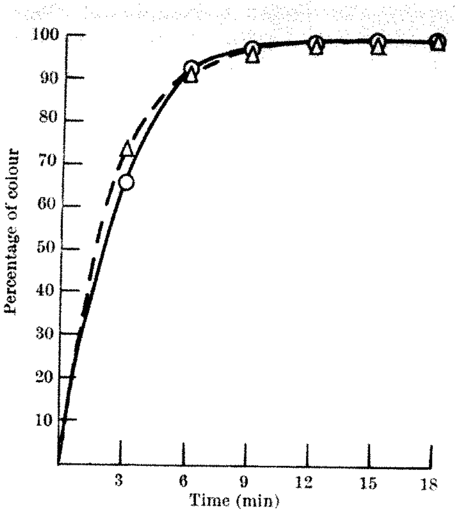

Fig. 1. Rate of development of colour at 100° C. Equal parts of 0·04 per cent indole-HCl reagent and sample were used. ○, Tendon organ extract-indole; △, DNA-indole. Read at 490 mμ. Cell length was 1 cm. The concentration of the sample was 30 μg/ml.

This communication describes a specific method, and its use in determining cell numbers in rabbit tendons. First, the diploid amount of rabbit nuclear DNA was established by counting and analysing three morphologically distinct populations of rabbit cells, namely, peritoneal leucocytes, thymocytes and nuclei extracted from kidney cortex. Cells and nuclei were suspended in physiological medium and each population was counted in a haemocytometer. Aliquots of the same individual cell suspensions were homogenized and analysed for DNA content using a modification of the Schmidt–Tannhauser procedure[4]. The desoxyribose fraction was measured in a Unicam *SP*500 spectrophotometer using the modified reaction with diphenylamine[5] against a standard calibration curve prepared from serial dilutions of a pure solution of desoxyribose treated in the same way. (The curve was linear up to a sample concentration of 0·1 μmoles/ml., giving a useful range over 0·02–0·1 μmoles/ml.)

The DNA content was then calculated on the basis that the purine/pyrimidine base ratio is unity, that the diphenylamine reacts with the sugar residues originally combined with purines in the DNA[6], and that the DNA–P content is 9·4 per cent.

Table 1 shows the range of rabbit diploid nuclear DNA values measured in pg (1 pg$=10^{-12}$ g) obtained from the three cell populations examined.

Fresh portions of adult rabbit tibialis anterior and peroneus longus tendons, freed from their sheaths, were finely sliced and submitted to the fractionation procedure outlined by Munro and Fleck[7]. DNA content was determined using the indole reaction[8] and a standard calibration curve prepared from serial dilutions of a solution of purified calf thymus DNA reacted with indole (a linear curve for the range 10–80 μg/ml.).

The specificity of the method was tested by comparing the absorption spectra of the tendon extract–indole compound with a pure DNA–indole compound[9]. Both wave forms showed the characteristic flattening at 460 mμ with a maximum peak absorption at 490 mμ, suggesting that the compounds formed in each case were identical. Further confirmation of this was obtained when rates of colour development were compared (Fig. 1). Table 2 gives results of recovery experiments with digests of tendon. Measured amounts of DNA were added to tendon extract solutions of known DNA concentration and the total recoveries were measured after the reaction with indole.

Although a number of factors will govern the choice of a particular method for cell population determination in a given tissue, the method described here is probably the most satisfactory one available for measuring cell numbers in tendon and other forms of dense, regular, connective tissues such as ligaments or aponeuroses.

IMMUNOLOGY

Gamma Globulin Production and Antibody Synthesis in Chickens bursectomized as Embryos

DEVELOPMENT of the immunoglobulin producing system of cells is controlled by the avian bursa of Fabricius[1,2]. Elucidation of the role of the bursa in developing immunological potential began with the discovery that surgical removal of this hindgut lymphoid organ in the newly hatched chicken prevents later development of normal antibody response[3]. Depression of antibody response is greatest when the bursa is removed immediately after hatching. After 8–10 weeks, bursectomy alone no longer has a demonstrable effect on antibody response[4]. It was discovered later that normal embryonic development of the bursa could be inhibited by testosterone or other androgens[5]. Chickens which are given testosterone during embryonic life are often even more immunologically deficient than chickens which are subjected to bursal removal at hatching. Chickens which are surgically or hormonally bursectomized have reduced numbers of plasma cells and decreased levels of circulating gamma globulin. Near lethal whole body irradiation of newly hatched chicks in addition to bursectomy completely prevents later development of germinal centres and plasma cells and such chickens are agammaglobulinaemic[6,7]. Germinal centres, plasma cells and immunoglobulin synthesis can be restored in bursectomized-irradiated chicks by injection of their unirradiated bursal lymphocytes[8]. These observations suggest that the bursa could be the only source of the germinal centre and plasma cell line but that some radiosensitive bursal cells leave the bursa before hatching.

In these experiments with embryonic bursectomy, we show that the role of the bursa in development of a competent immunoglobulin-producing cell system is a sequential process in a qualitative way: bursal support of development of capacity for 7*S* immunoglobulin synthesis occurs after the integrity of the 19*S* immunoglobulin synthesis system has been established.

All experimental chickens were from a single hatch of Ghostly Pearl White Leghorn eggs. The bursa of Fabricius was surgically removed on the nineteenth day of incubation in one group of birds and on the day of hatching in another. Birds in another group were subjected to a sham bursectomy procedure on the nineteenth day of incubation. The rest of the hatched chickens were kept as an unoperated control group.

Bursectomy of the 19 day old embryo was performed by cutting a 1·5 × 2 cm hole in the egg shell overlying the tail; the tail was pulled out through a small opening in the vascular chorioallantoic membrane. Through a lateral incision, dorsal to the cloacal vent, the bursa was dissected and removed by cutting the base of its stalk attachment to the posterior cloacal wall. Following bursectomy the embryo was replaced in the egg, the opening was sealed with transparent tape and the egg was returned to the incubator. In sham bursectomies, the entire procedure was carried out except for cutting the bursal stalk. All procedures were performed aseptically.

Of thirty-six embryos which were bursectomized on the nineteenth day of incubation, twenty-five hatched; one of these was destroyed because of a herniated gut. All the twelve embryos which were subjected to sham bursectomy hatched as normal chicks. All groups of birds survived equally well until the fifth week after hatching (Fig. 1). By this time, most of the maternal 7*S* immunoglobulins derived from the yolk had been catabolized. After the sixth week, there was a sharp decline in survival of both groups of bursectomized chickens.

Chickens surviving at 4 weeks were weighed, bled and injected intramuscularly with 10^9 washed sheep erythrocytes. One week later the chickens were again bled and injected with 10^9 sheep erythrocytes. Bleeding was repeated on days 14 and 17 after the initial injection. The sera which were collected at these times were tested for the ability to agglutinate sheep erythrocytes by a microagglutination technique[9] and were assayed for 19*S* and 7*S* immunoglobulins by immunoelectrophoretic analysis using specific antiserum to chicken 19*S* and 7*S* gamma globulins prepared in goats[7].

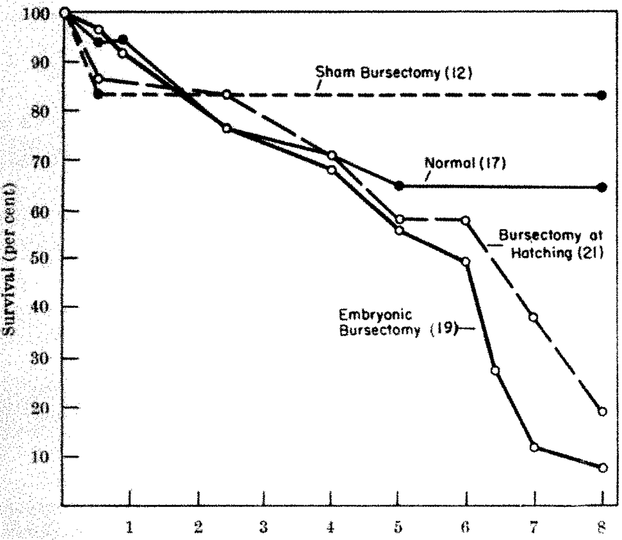

Fig. 1. The effect of embryonic (19 days) and post-hatching (21 days) bursectomy on survival of chickens.

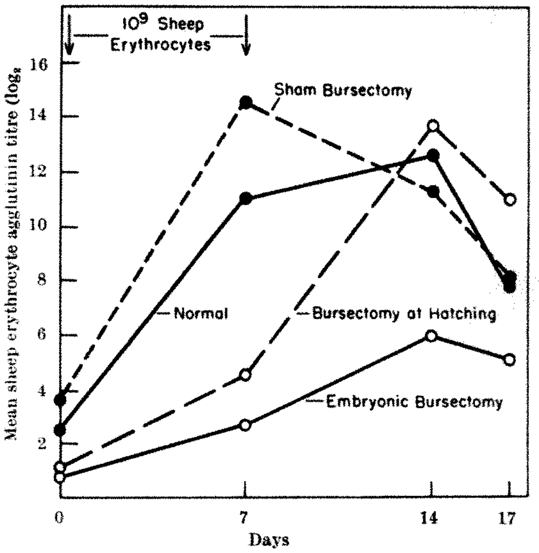

Fig. 2. Antibody titres before and after immunization of 4 week old chickens with sheep erythrocytes on day 0 and day 7. The curves show the mean agglutinin titres for the chickens which were bursectomized as embryos (19 days), bursectomized post-hatching, sham bursectomy, and normals.

The agglutinating antibody responses of the experimental chickens are shown in Fig. 2. Birds which were subjected to bursectomy at hatching had depressed antibody responses after primary immunization with sheep erythrocytes but, as others have found[10,11], they responded as well as controls did to secondary immunization. Birds which were deprived of their bursae at day 19 of embryonic life had barely detectable primary antibody responses and had feeble responses even after secondary immunization. The mean levels of antibodies in this group of birds were significantly lower than those of all other groups of birds after both primary and secondary immunizations.

Analysis of circulating immunoglobulins showed a striking reduction of 7*S* immunoglobulin content in each bird which was subjected to bursectomy at the nineteenth day of embryonic life. Even in this group of birds, however, 19*S* immunoglobulin levels were normal. A typical immunoelectrophoretic pattern of the serum of one of these dysgammaglobulinaemic birds is shown in Fig. 3. By contrast, less than 30 per cent of the birds from this strain which were bursectomized at hatching had this serum pattern of low 7*S* but normal 19*S* immunoglobulins (Table 1).

Table 1. GAMMA GLOBULIN PATTERNS AS EVALUATED BY IMMUNOELECTROPHORESIS OF SERUM FROM BURSECTOMIZED CHICKENS DURING THE SIXTH WEEK AFTER HATCHING

Group	Normal 19*S* low 7*S*	Normal 19*S* and 7*S*
Bursectomy at 19 days	10*	0
Bursectomy at 21 days	4	10
Sham	0	10
Normal	0	11

* No. of sera tested.

Tissue sections of the spleens and caecal tonsils from birds which died or which were killed on the conclusion of these studies were histologically examined with particular reference to germinal centre and plasma cell development. The number of germinal centres, and probably plasma cells, were reduced in the tissues of both groups of bursectomized animals. Both germinal centres and mature plasma cells were present in tissues from all groups of experimental animals, however, and the cells seemed morphologically normal.

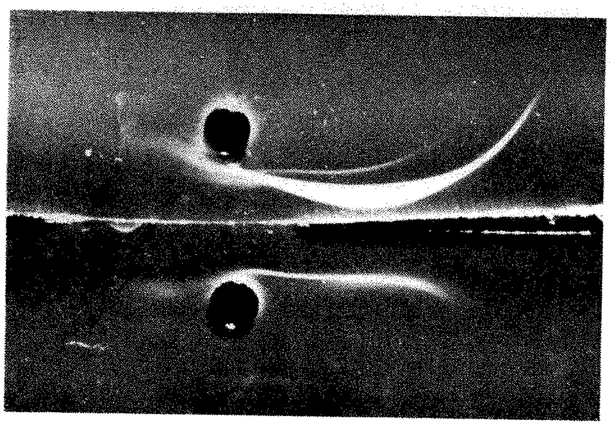

Fig. 3. Immunoelectrophoresis pattern of normal chicken serum (top) and typical embryonic bursectomized chicken serum (bottom) at 6 weeks of age. The amount of $7S$ gamma globulin in the embryonic bursectomized chicken was only 15 per cent of that found in normal chickens. Goat antiserum to chicken gamma globulin in the trough.

Severe depression of $7S$ immunoglobulin contents in birds showing intact $19S$ immunoglobulin synthesis has occurred after surgical bursectomy at hatching[6,7,12], after hormonal bursectomy[13], and rarely as a genetically determined spontaneous event[14]. Over the past several years in studies involving many hundreds of bursectomized chickens in our laboratory, we have found that approximately 20 per cent of birds which are subjected to bursectomy as newly hatched chicks, develop this type of experimental dysgammaglobulinaemia, but the incidence has varied from 5 per cent to 50 per cent in different experimental groups of birds. In the present experiments, we consistently produced this dysgammaglobulinaemic pattern by removing the bursa 2 days before hatching whereas bursectomy immediately after hatching led only to a 30 per cent incidence. The observations indicate a bursa-controlled sequential maturation of the immunoglobulin-producing system of cells somewhat analogous to that observed in differentiation of the haemoglobulin-producing system of cells[15-17].

A central question raised here is how the bursa regulates this stepwise differentiation pattern. One possibility is that $19S$ immunoglobulin-synthesizing cells arise from a source other than the bursa. Against this interpretation, the developing immunoglobulin-producing system vigorously springs back after heavy total body irradiation but fails completely after bursectomy and irradiation[6,7]. Furthermore, unirradiated bursal lymphoid cells from newly hatched chicks are capable of restoring the immunoglobulin-producing cell system in bursectomized-irradiated birds[8]. Chickens restored in this manner synthesize both $19S$ and $7S$ immunoglobulins strongly suggesting that, by the time of hatching, bursal cells are capable of differentiating into both $19S$ and $7S$ immunoglobulin producers. Another possibility, which seems unlikely to us, is that the bursa secretes a hormone which regulates a differentiation of lymphoid cells resulting in the shift from only $19S$ to both $19S$ and $7S$ immunoglobulin synthesis. Evidence favouring a hormonal function for the bursa has been presented[18], but we have recently shown that the proposed bursa hormonal action might be attributable to bacterial contamination of bursa explants by means of endotoxin enhancement of the remaining potential of recipient bursectomized animals[19].

Two remaining alternatives seem attractive. The first is that the difference in immunoglobulin synthesizing capability after bursectomy at 19 compared with 21 days merely reflects the numbers of stem cells which were seeded from the bursa before its removal. The second alternative is that the earliest stem cells seeded from the bursa are qualitatively different in that they are only capable of differentiation toward IgM synthesis whereas stem cells residing within the bursa for a longer period of time can give rise to an ancestral line of cells capable of either $19S$ or $7S$ immunoglobulin synthesis.

Theoretical support for the first alternative might be provided by Sterzl's contention that supersaturation of antigen-committable immunoglobulin-producing cells by antigen promotes differentiation to $19S$ antibody synthesis while suppressing the cell division necessary for the activation of $7S$ antibody synthesis[20,21]. According to this view, the small number of stem cells seeding from the bursa by the nineteenth day might easily be saturated by environmental antigens with preferential enhancement of $19S$ immunoglobulin synthesis. This interpretation would suggest that administration of large amounts of antigens beginning at hatching would increase the incidence of dysgammaglobulinaemia in birds which were bursectomized at 21 days; we have not, however, been able to alter the incidence of dysgammaglobulinaemia by such treatment.

In support of the latter alternative we have found that there is a difference in nucleic acid ratios of bursal lymphoid cells at different stages of embryonic life. The ratio of RNA to DNA in these cells drops sharply on about the nineteenth day[1]. Further evidence has been provided by Thorbecke and Warner[2], who have found that bursal fragments of 19 day old embryos produced only $19S$ immunoglobulins in short term tissue culture whereas small amounts of both $19S$ and $7S$ were produced by bursal explants obtained from chickens later in life.

PATHOLOGY

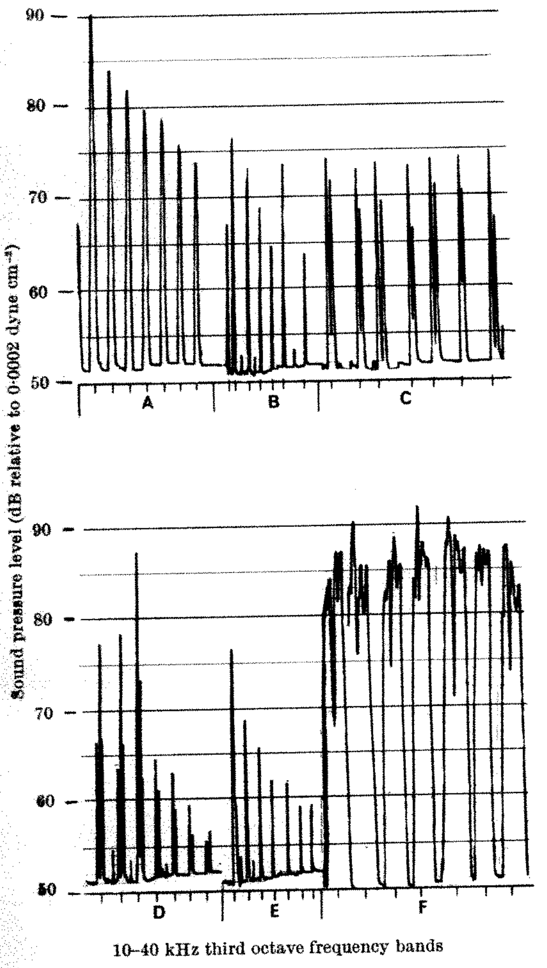
Asthma and the High Frequency Sound Environment

ASTHMA is a disturbance of the respiratory mechanism involving reversible, partial obstruction of the airway. One symptom is a raised sensitivity in human relationships. In a previous communication it has been shown that sufferers from asthma are unusually sensitive to high frequency sound waves between 10 and 30 kHz[1]. In this communication, an investigation of the high frequency sound environment is described, from which it may be inferred that these frequencies play a part in human communications.

The instruments which were used were the Holgate ultrasonic detector, which transduces high frequency sound to more audible low frequency signals, and the Bruel and Kjaer sound spectrometer, which was used to record the root mean square of the amplitude of the sounds which were tested. The microphone (a 0·5 in. condenser) was suspended in an anechoic chamber, some 55 cm from the sound source, and the amplitude of the sound was measured at 10, 12·5, 16, 20, 25, 31·5 and 40 kHz.

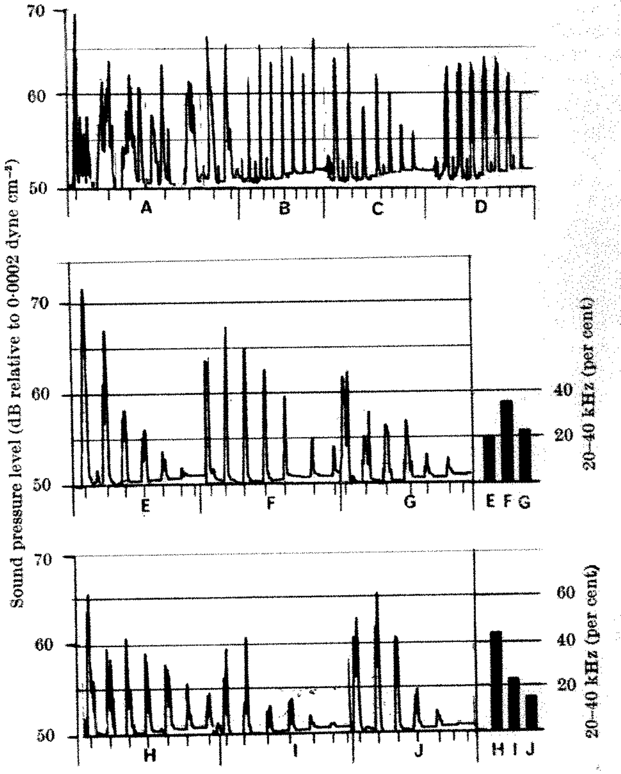
Initially, it was found that high frequency sound formed an important component of sounds which were associated with disturbances of an arresting or irritating nature, for example, the rustling of paper, the ringing of alarm bells or the sudden opening of metal catches. Certain children's toys, such as baby rattles or toy xylophones, also produced significant amounts of high frequency sounds. Various human activities were also found to involve the production of high frequency sound, such as eating an apple or lettuce, snapping the fingers, coughing, scratching the skin and, particularly, shouting and screaming of children. Examples of spectrograms of some of these sounds are shown (Figs. 1 and 2).

The voices of a few volunteer subjects were then tested to find short words of definite emotional content which could be analysed by the spectrometer. The words chosen were "mummy", "daddy", Christian names, "yes", "no", "please", "stop it", and, in addition, it was thought that the letters of the English alphabet covered most of the sounds which were used in lettered speech and, being well known, could be easily recited even by young children.



10–40 kHz third octave frequency bands

Fig. 1. The sound spectrograms of: *A*, a child screaming; *B*, forced breathing; *C*, coughing; *D*, baby's rattle; *E*, toy xylophone; *F*, alarm bell, all recorded at 10, 12·5, 16, 20, 25, 31·5 and 40 kHz.



10–40 kHz third octave frequency bands

Fig. 2. The sound spectrograms of: *A*, eating an apple; *B*, scratching the skin; *C*, snapping the fingers; *D*, rustling paper; *E*, yes; *F*, no; *G*, please; *H*, stop it; *I*, mummy; *J*, daddy, all recorded as in Fig. 1. *E* to *J* are test words and the equivalent percentage of ultrasonics (dB) are shown as histograms (right hand ordinate).

From the preliminary results which were obtained, an experiment was designed to contrast the high frequency content of the speech of normal and asthmatic families.

An asthmatic family was defined as one possessing one or more members who had, at one time or another, exhibited asthmatic attacks. The control families had no such members. The asthmatic attacks were not all of the same severity, persistence and frequency, and some asthmatic subjects had not had attacks for many months. The children in both groups were classified as first born, second born, third born, and so on, but their age and sex were not taken into account. The youngest child it was possible to test was 4 yr old, and the oldest adolescent which was classified as a child was 18 yr old.

All the members of any family were asked to say into the microphone the words and letters suggested. The parents also said their own and each other's Christian names. It was then possible to contrast not only the way in which a parent in either group of families spoke the same test words and letters, but also the way in which succeeding children in a family were addressed. This was done because of the odd frequency distribution of asthmatics in the test families: 48 per cent first born, 35 per cent second born, 13 per cent third born, 4 per cent fourth born, 0 per cent fifth born; a circumstance which, although it could result from chance, aroused suspicions ($\chi^2 = 7{\cdot}4$, $n=4$, $P=0{\cdot}12$).

The subjects were seated so that they spoke some 55 cm from the microphone at the same height; they were told to speak directly into it and not to drop their heads while they were speaking: this is important, as high frequency sound is very directional. They were tested as far as possible in the presence of the rest of the family, and in a random order. Each word had to be spoken seven times so that the seven frequency bands which were tested between 10 and 40 kHz could be analysed by the spectrometer. Seven times was found to be the limit a short word could be repetitively and consistently spoken. With the apparatus used it was not possible to analyse all seven frequency bands simultaneously. The letters of the alphabet were spoken once only and were analysed at the single frequency of 20 kHz because repetition would cause tiredness and loss of interest by the subject.

In all, 106 subjects were tested and comparisons were made on the basis of the percentage of sound (dB) above 20 kHz in each spectrogram, that is between the relative amount of ultrasonics produced by each subject when saying the test words.

An example of the conversion of six test word spectrograms into the equivalent histograms of the ultrasonic percentage is shown in Fig. 2 In order to reduce the influence of particular letters, the results from saying "yes", "please", "no" and "stop it" were summed. In each group, the mean histograms of each parent, both parents together, and the four classes of children are plotted in Fig. 3. With the aid of a digital computer, the significance of the differences between the histograms of the different classes was investigated and it was found that with respect to the control group, the following differences in the asthmatic group were statistically significant.

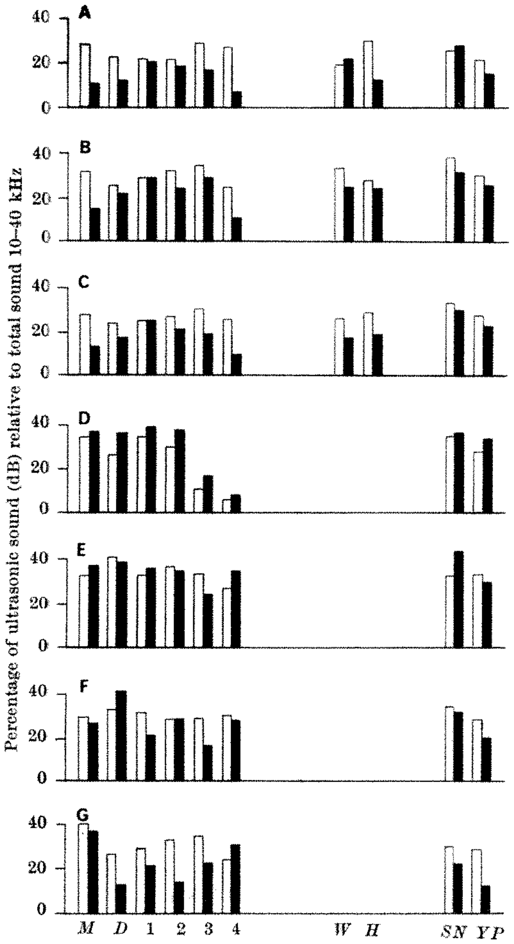


Fig. 3. These histograms represent the relative percentages of ultrasonics (dB) which were produced when the following were spoken: *M*, mummy; *D*, daddy; the Christian names of (1) the first born child; (2) the second born child; (3) the third born child; (4) the fourth born child; *W*, mother; *H*, father; *SN*, average of stop it and no; *YP*, average of yes and please. White columns refer to the asthmatic group and black columns to the control group of subjects. Class *A* consists of the mean histograms of seventeen asthmatics and ten control mothers; class *B* consists of fourteen asthmatic and ten control fathers; class *C* represents the mean of the subjects in (*A*) and (*B*) combined into one class as parents; class *D* is the mean of thirteen asthmatic and nine control first born children; class *E* is the mean of thirteen asthmatic and seven control second born children; class *F* is the mean of eight asthmatic and two control third born children; class *G* is the mean of two asthmatic fourth born children and the histogram of one fourth born child.

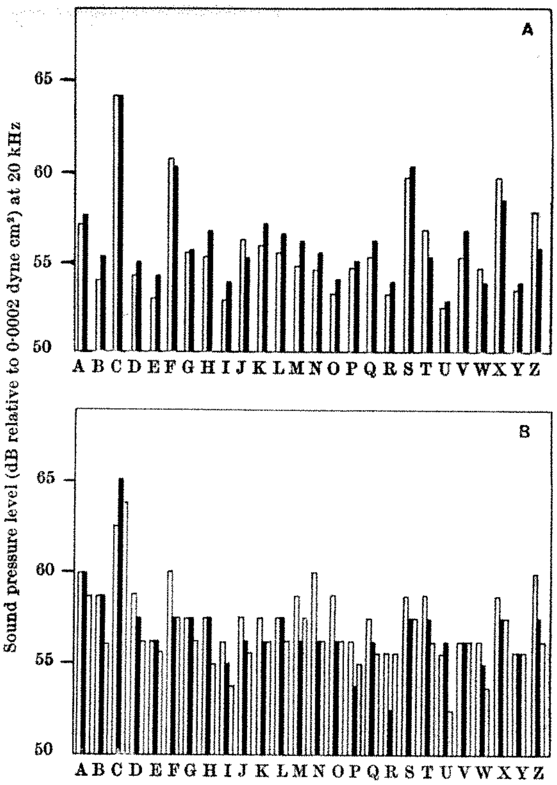

Fig. 4. The histograms of sound pressure levels which were produced when pronouncing the letters of the English alphabet recorded with a third octave band analyser at 20 kHz. *A*, White columns represent mean of twenty-nine asthmatic group parents, and black columns represent the mean of twenty control group parents. *B*, Left hand white column represents the mean of the seventeen children in the asthmatic group who have had asthmatic attacks, and the centre black column represents the mean of the fifteen children in the asthmatic group who have not had asthma. The right hand white column represents the mean of the twenty-two children in the control group.

In class *A* (Fig. 3) the mothers produced more ultrasonics than controls did when saying: (1) mummy ($t=3{\cdot}3$, $n=25$, $P=0{\cdot}01$); (2) daddy ($t=2{\cdot}26$, $n=25$, $P=0{\cdot}04$); (3) the Christian name of the father ($t=3{\cdot}85$, $n=20$, $P=0{\cdot}001$).

In class *B* (Fig. 3) the fathers produced more ultrasonics than controls when saying: (1) mummy ($t=2{\cdot}2$, $n=22$, $P=0{\cdot}05$); (2) the Christian names of the third child ($t=3{\cdot}27$, $n=10$, $P=0{\cdot}01$); (3) the Christian name of the fourth child ($t=5{\cdot}19$, $n=4$, $P=0{\cdot}01$).

In class *C* (Fig. 3) both parents together produced more ultrasonics than controls did for the words : (1) mummy ($t=3{\cdot}6$, $n=50$, $P=0{\cdot}001$) ; (2) the Christian name of the third child ($t=3{\cdot}8$, $n=24$, $P=0{\cdot}01$) ; (3) the Christian name of the fourth child ($t=3{\cdot}4$, $n=11$, $P=0{\cdot}01$); (4) the Christian name of the father ($t=2{\cdot}9$, $n=44$, $P=0{\cdot}01$).

In classes *D* (Fig. 3) to *G* no significant differences were found between the children of the asthmatic and control groups. Mean histograms of the sound pressure levels of letters of the alphabet, recorded with a third octave band analyser, at 20 kHz are plotted in Fig. 4. The only difference which occurs is between children of the asthmatic group who have had asthma and children of the normal group and this is for the two letters Q and Z ($t=2{\cdot}34$, $n=27$, $P=0{\cdot}04$; $t=2{\cdot}25$, $n=27$, $P=0{\cdot}04$) (Fig. 4): otherwise there were no significant differences between the groups.

The results were obtained by testing subjects for a short time with a few words and letters in the somewhat artificial conditions of the laboratory. Although the circumstances surrounding the test were made as routine as possible, the procedure is in practice not very easy, particularly for children. Thus the conclusions to be drawn can only be tentative.

In my opinion, the results which I obtained support the clinical impression that the voices of parents in the asthmatic group sound different to the ears of the observer from the voices of the parents in the control group, and they retain a childlike quality. If the very young asthmatic child with its unusual sensitivity to high frequency sound could instinctively perceive this difference, it might explain some of its behavioural characteristics. Much information could be obtained by the very young child, if he or she noted the frequency at which sound waves from a particular source were no longer perceived, that is if it followed the upper limit of the total band width. Thus it is possible that the high frequency content of speech, hitherto supposed to be of negligible importance[3], might be of use, particularly to children, in the communication of emotional states as observed by Sewell in the rat[2].

I thank the Medical Research Council for providing the Holgate ultrasonic detector, and for kind advice and encouragement; B. R. Webster, C. S. Henson and B. G. Sweet for providing the sound spectrometer, for allowing me to use the digital computer and for help and advice; Dr I. Sutherland for advice and technical help; G. Battin for aid in the preparation of the drawings; and Professor E. J. Denton and Dr Q. Bone for helpful discussions. This work was supported by the Plymouth College of Technology.

Lack of Complement Fixing Antigens in DMBA-induced Leukaemia of Rats

MOUSE leukaemia viruses have not induced overt cytopathic effects in tissue cultures and so the complement fixation technique has been used to detect virus antigens in tissue cultures[1]. The technique involved sera of rats which were carrying transplanted tumours originally induced by leukaemogenic virus, and extracts of rat tumours. Germ-free and normal rats developed lesions of myelogenous leukaemia after repeated intraperitoneal administrations of sterile 7,12-dimethylbenz(a)anthracene (DMBA) in fat[2,3]. Viral flora could not be detected in their tissues by electron microscopy, nor by other extensive examinations[4]. This communication describes the use of the complement fixation technique in a search for disease-related antigens in rats with DMBA-induced leukaemia.

Nineteen Lobund germ-free rats with lesions of primary leukaemia which was induced by DMBA, and twenty normal rats with transplanted leukaemia induced by DMBA, were examined. The rats were of three strains: Sprague–Dawley, Wistar and Fischer. Blood, leukaemic tumour and infiltrated liver and spleen tissues were collected from each rat. Serum was separated, inactivated at 56° C for 30 min and stored at $-20°$ C. Tumours and other organs were homogenized in Eagle's medium with penicillin and streptomycin to a concentration of 10 per cent, centrifuged at 2,500 r.p.m. for 30 min and the supernatant fluids were stored at $-70°$ C until they were used.

Germ-free Wistar rat embryos were dispersed with trypsin at 15 days of age and confluent cell sheets of primary or secondary cultures were used for production of antigens. Rat embryo tissue cultures in 32 ounce bottles were seeded with 2 c.c. of organ and tumour extracts, and Eagle's medium with streptomycin and 10 per cent heat-inactivated calf serum was added as nutrient medium. The seeded and control rat embryo tissue cultures were incubated at 37° C for 21 days without changing the nutrient fluid, but the *p*H was adjusted by adding a 5 per cent solution of sodium bicarbonate. At the end of the incubation period, three test antigens were prepared from each tissue culture[5]: (*a*) nutrient fluid; (*b*) ten-fold concentrated nutrient fluid; and (*c*) cells scraped from the glass and re-suspended in 2 ml. of nutrient fluid. The preparations were frozen and thawed three times, centrifuged at 2,500 r.p.m. for 30 min, and stored at $-70°$ C until they were used.

A suspension of thymoma cells from a Sprague–Dawley rat which was infected with Gross leukaemia virus was injected subcutaneously into conventional weanling rats of the same strain. Tumours appeared at the site of injection after one week, and 6 weeks later the rats were bled and sera were collected. Each serum was examined by complement fixation test according to the micro-titre technique[6], with antigen prepared from a 10 per cent extract of the tumour. All the sera were positive and the titres ranged from 1 : 16 to 1 : 64. Sera were pooled accordingly and stored at $-70°$ C for use as reference anti-Gross leukaemia sera.

The four preparations from the organs and the tumours of DMBA and of rats inoculated with Gross virus were tested as antigens with antiserum which was collected from rats with (*a*) primary leukaemia which was induced by DMBA, (*b*) transplanted leukaemia which was induced by DMBA and (*c*) lymphoma induced by Gross virus (Table 1).

Table 1. COMPLEMENT FIXATION TESTS WITH VIRUS AND WITH DMBA-INDUCED LEUKAEMIA OF RATS

Antigens	Complement fixation antibody in rats with Primary DMBA tumour	Transplanted DMBA tumour	Gross virus lymphoma
Organ extracts			
(1) Primary	–	–	–
(2) Transplanted	–	–	–
(3) Gross lymphoma	–	–	+
Tissue culture preparations			
(1) Primary	–	–	–
(2) Transplanted	–	–	–
(3) Gross lymphoma	–	–	+

Examinations of antigens from Gross lymphoma and antiserum from rats with Gross lymphoma were the only combinations in which complement was fixed. Antigens which were prepared from leukaemia induced by DMBA did not fix complement with sera collected from homologous rats nor from rats with Gross lymphoma. Furthermore, antigens prepared from Gross lymphomas did not fix complement when examined with sera from rats with DMBA-induced leukaemia. Sera from twenty normal germ-free rats were examined for complement fixing antibodies against Gross lymphoma antigen, and four gave reactions of ± at 1 : 2 dilution of serum. Similar results were reported to us by Dr Wallace P. Rowe of Bethesda. We cannot explain the presence or the nature of the antibodies to Gross virus in the germ-free rats. Virus has not been detected in the rats and the latter did not develop lymphatic leukaemia unless they were inoculated at birth with Gross leukaemia virus[4].

Gross and FMR complement fixing antigens have been detected in tissue cultures by Hartley and Rowe[1,7]. Complement fixing antigens and antibodies from Gross virus-inoculated rats were shown by us and were used as positive reference reagents for the tests of the unknown sera and antigens. Sera and antigens from DMBA-leukaemic rats were examined with Gross virus reference reagents, but complement fixation was not observed. Negative results in the complement fixation tests on the experimental rats would indicate that they did not produce antibodies or antigens to Gross virus. Furthermore, negative results were obtained when homologous DMBA related antigens and antibodies were examined, which suggested that they did not produce complement fixing antigens at all. These results support the concept[4] that the myelogenous leukaemia which is induced by DMBA in rats bears no relation to Gross leukaemia virus or to other antigenic viruses and can be considered as virus-free.

We thank the Upjohn Company, Kalamazoo, Michigan, for the DMBA in fat. This work was supported by a US Public Health Service grant and the Galvin Foundation.

Transport Piece in the Urines of Premature Infants

IN 1965 Tomasi *et al.*[1] presented evidence that the IgA in saliva and colostrum are similar but differ from serum IgA in that they have a higher sedimentation coefficient and an additional antigenic determinant. Later, South *et al.*[2] confirmed and extended the discoveries of Tomasi *et al.* and observed that IgA can be selectively transported from serum into saliva and that salivary IgA can be dissociated into two antigenically distinct components by reduction with 2-mercaptoethanol. One of the components was immunochemically similar to serum IgA, and the other immunochemically identical to a protein, the transport piece demonstrable in saliva of patients lacking both serum and salivary IgA. They noted that transport piece is present in an unbound form in the saliva of most children and some adults. During the course of a longitudinal study carried out to determine the nature of proteins in urine of premature and full-term infants (our unpublished work) the experiments described here were carried out to determine if transport piece is present in the urine of premature infants.

Twenty-four hour urine samples were collected into a bottle packed in ice from premature infants in the Premature Research Center at the Palo Alto–Stanford Hospital and from full-term infants in the regular nursery. Bladder urine was also collected immediately after birth from ten full-term infants. All urines were dialysed against deionized water at 4° C for 24–48 h and then lyophilized. The resulting dry powders were reconstituted with 0·15 molar sodium chloride to effect a 200–400-fold concentration of the original urine sample.

Antiserum against human serum IgA was purchased from Hyland Laboratories, Los Angeles, California, and adsorbed with serum from an individual lacking serum IgA. When reacted against normal human serum, saliva, colostrum, urine, nasal secretion or sweat in immunoelectrophoresis or gel diffusion, this antiserum gave a single precipitin arc and a reaction of identity between the precipitin arc of serum and those of the various body secretions. An antiserum against secretory IgA was produced in rabbits using IgA isolated by chromatography of normal human colostrum. The antiserum was adsorbed with human serum devoid of IgA. In gel diffusion experiments this antiserum gave a single precipitin band with normal human serum, a reaction of identity between the precipitin arcs of colostrum, saliva, nasal secretions and spurring of the precipitin lines obtained with each of these secretions over the serum IgA precipitin arc.

Table 1. PRESENCE OF URINARY TRANSPORT PIECE AND SECRETORY IgA IN INFANTS

Group	Weight at time of urine collection	No. of infants*	Days after birth urine collected	Free transport piece	Secretory IgA
Premature infants*	860–1,100	5	8–17	+	0
	1,101–1,500	12	6–42	+	0
	1,501–2,000	16	5–56	+	0
	2,001–2,500	13	28–77	+	+
	2,501–2,800	3	43–93	+	+
	4,850–6,500	5	111–195	+	+
Full-term infants	2,948–3,827	5	6	+	0
Bladder urine of newborn infants	2,951–3,632	10	1	+	+ †
Older children	—	9	8–12 yr	+	+

* Figures represent the number of infants in the designated weight group whose 24 h urine samples were pooled.

† See text.

An antiserum specific for transport piece was made by adsorbing the antisecretory IgA antiserum with serum IgA; similar antiserum was supplied by Dr Richard Hong of the University of Minnesota School of Medicine. These antisera gave no precipitin arcs when reacted by double diffusion in agar with normal human serum, 1 per cent serum IgG or 1 per cent serum IgA.

Table 1 summarizes data from pooled urine obtained from premature and full-term infants. The weight groups represent data from infants tested once and from infants who were studied repeatedly as they grew and gained weight in the nursery. Transport piece was present in urines collected from premature infants in each of the six weight divisions as well as from full-term infants and older children. Secretory IgA was demonstrable in the pools of concentrated urines and in a number of individual urines of premature infants weighing more than 2,000 g and of older children. Only one of ten individual bladder urines from full-term infants revealed IgA, but each contained transport piece. Examination of individual and pooled urines of premature infants in the first three weight groups did not reveal IgA. When urines of individual infants weighing 860–1,500 g were reacted with the antibody against purified colostral IgA, a single precipitin band formed (transport piece) which gave a reaction of complete non-identity with serum IgA and of partial identity with colostral and salivary IgA. Urines containing IgA often showed two precipitin bands with this antiserum, one of which gave a reaction of identity with colostral IgA and the other (nearest the antiserum well) a reaction of identity with the transport piece precipitin arc of urines without demonstrable IgA. Thus free transport piece was demonstrable in urines which contained secretory IgA, a finding similar to that described by South *et al.*[2] in saliva of newborn babies. Using the antiserum against colostral IgA and this same antiserum after it had been adsorbed with serum IgA, the transport piece in these urines was seen to migrate in immunoelectrophoretic patterns with the electrophoretic mobility of a fast gamma globulin.

Longitudinal studies were carried out in the five infants weighing between 860 and 1,100 g to determine whether transport piece persists in the urine and to determine the onset of appearance of secretory IgA. At birth, this group weighed between 947 and 1,134 g, representing gestational ages of between 25 and 31 weeks, based on the weight estimates of Lubchenco *et al.*[3]. Representative data in two of these infants (the lightest and heaviest in this weight group) and in one infant in the third weight group are shown in Table 2. The appearance of IgA in the urine of these infants did not appear to be related so much to the number of days after birth as to the weight of the infant.

Amniotic fluid was obtained, free of contamination by

Table 2. LONGITUDINAL STUDIES OF URINARY TRANSPORT PIECE AND IgA IN PREMATURE INFANTS

maternal blood, from seven pregnancies, by amniocentesis. Approximate gestational ages of the foetuses at the time of amniocentesis and volumes of fluid obtained were 14 weeks (150 ml. and 48 ml.), 17 weeks (141 ml.), 19 weeks (135 ml. and 74 ml.) and 40 weeks (134 ml. and 9 ml.). The fluid was dialysed for 24 h, lyophilized and reconstituted in 0·15 molar sodium chloride to obtain a concentration approximately 100 times the original. Transport piece was not demonstrable in the amniotic fluid obtained from the five foetuses less than 19 weeks old but was found in the two fluids from the 40 week old foetuses.

Individual serum samples from four infants in each of the premature weight groups were tested for the presence of IgA, which was not demonstrable in the serum of infants weighing 860–1,100 g but was present in the serum of two of the four infants weighing 1,101–1,500 g and in all of the sera tested from the infants in the other four weight groups.

The studies described here demonstrate the presence of transport piece in the urine of premature infants and suggest that transport piece is produced *in utero*. These data do not define the origin of the transport piece demonstrable in these urines which may have originated in either the infant's urinary tract or serum. Because transport piece has been described in the saliva of older infants[2], it may be that this protein is cleared by the kidneys after its passage into the blood stream from multiple sites (such as nose, gut and salivary glands).

Infants weighing as little as 2,001–2,500 g had secretory IgA in their urine, and IgA was also detectable in their sera. The inability to detect IgA in urine of infants of lower weight despite the presence of IgA in their sera may have been a result of the smaller volumes of urine available from these infants for concentration.

South *et al.*[2] stated that newborn babies, although they have no IgA in saliva, have transport piece. The present studies support their findings of the presence in newborns of transport piece and suggest that transport piece is produced *in utero*, probably at least as early as the sixth to seventh month of gestation.

It is interesting to note that a transport protein was present in utero, of certain of these infants and foetuses in the absence of the material to be transported—IgA. We wonder if the presence of transport piece is a remnant of a phylogenetically important protein and represents a mechanism of host resistance to early invasion by pathogens. *In utero* infection can stimulate *in utero* production of IgA[4–6] which might then be transported to the infants' secretions by means of transport piece already present. It would thus be interesting to know whether high concentrations of secretory IgA are present in the saliva or urine of newborn infants who had been exposed to *in utero* infection when localized IgA response in the secretory glands could be very strong. That infection may be necessary for this to occur, if it does at all, is suggested by the findings of Haworth and Dilling[7]. They noted the presence of IgA in the sera, but not saliva, of seven infants who had received exchange transfusions at birth. IgA appeared in the saliva of these infants at the same age as in infants who did not have transfusions.

During this study, Bienenstock and Tomasi[8] reported the presence of secretory IgA in human urine and found it to be identical to the IgA of saliva and colostrum. Free "secretory piece" was found in all normal urines tested including agammaglobulinaemic urine.

If transport piece is produced during gestation and excreted into the urine, it might be expected in amniotic fluid[9]. Unfortunately, amniotic fluid was not available from foetuses in the 6–8 month gestational age but rather from younger or older foetuses. Transport piece was demonstrable only in the amniotic fluid obtained from the two 40 week old foetuses. The origin of transport piece in the premature infants remains to be defined. There are no published data on foetal synthesis of transport piece, on placental transport of maternal transport piece or on placental production of this protein.

β-Alaninuria in Patients with Tuberculosis

A HIGH incidence of a high voltage electrophoretic band which is visualized with ninhydrin was noticed in the urine of patients with pulmonary tuberculosis during a study of the excretion of β-aminoisobutyric acid by patients with various pathological conditions. The mobility of the band was identical to that of β-alanine, and the identity was confirmed by paper chromatography and isolation.

Early morning urine was collected and a sample containing 1 mg of creatinine was evaporated in a vacuum desiccator over sulphuric acid and potassium hydroxide. One tenth of the solution of the residue was subjected to paper electrophoresis at a voltage gradient of 100 V/cm for 30 min at pH 3·4 (pyridine : acetic acid : water, 1 : 10 : 189). As standards, 2, 5 and 10 μg of β-alanine were run together with urine specimens. The dried strip was immersed in 0·25 per cent ninhydrin in a mixture of acetone, pyridine and acetic acid (17 : 1 : 2) and heated at 90° C for 5 min. A bluish purple band of β-alanine was eluted with 4 ml. of 50 per cent aqueous ethanol, and the eluate of the ninhydrin negative area was taken as a blank. The optical density was read at 590 mμ. An amount of less than 2 μg/mg creatinine was below the sensitivity of the method of determination and was expressed as zero in the tables. Recovery for 20 μg of β-alanine added to urine was 100 ± 5 and 102 ± 4 per cent in five urine specimens from patients with tuberculosis and fifteen specimens from normal subjects, respectively. The eluate of the band corresponding to β-alanine contained no ninhydrin positive substance other than β-alanine when urine specimens from tuberculous and normal subjects were examined by paper chromatograms, but urine specimens from patients with liver diseases occasionally contained another ninhydrin positive substance as well as β-alanine. The contaminated substance in the urine of patients with hepatic dysfunction could be removed by the adsorption of the urine on a column of 'Amberlite *IR*-120', H^+ form, followed by elution with 1 molar pyridine; the dried residue was used for the determination. The recovery of known amounts of β-alanine added to urine was 98 ± 3 per cent in fifteen estimations. The amounts of β-alanine in some urine specimens were determined simultaneously with an amino-acid analyser[1]. The amounts in six urine specimens were 0, 5, 0, 50, 55 and 50 μg/mg of creatinine with the electrophoretic method which are compared with 2·5, 4·0, 3·0, 48·3, 55·1 and 48·1 μg, respectively, found with the analyser. A reasonable agreement of the values obtained with the two methods provides support for the validity of the method of determination with electrophoresis.

Patients with pulmonary tuberculosis excreted, on average, more β-alanine than normal healthy subjects, and the concentrations of the amino-acid were beyond the normal range in two thirds of urine specimens of the patients. There was no significant difference in the concentration of creatinine in urine from patients with pulmonary tuberculosis and normal subjects. The increase in the amount of β-alanine in the patients was not related to drug treatment. The concentrations of β-alanine in the urine of patients who had not received any treatment were as great as those of the patients receiving antituberculous treatments, and there was no correlation between the amounts and kinds of drugs. In addition three patients with lung cancer who had received antituberculous drugs after the mistaken diagnosis of tuberculosis excreted less than 5 μg of β-alanine/mg of creatinine.

The identity of β-alanine was confirmed by the isolation of the amino-acid from 7 l. of pooled urine from patients with pulmonary tuberculosis. The urine was passed through a 6 × 45 cm column of 'Amberlite *IR*-120 × 8', H^+ form, and the resin was washed with 3·5 l. of water. The adsorbed amino-acids were eluted with 1 molar pyridine. A fraction of the eluate between 2·3 and 3·7 l. was evaporated to dryness *in vacuo* and the residue was applied to a 6 × 35 cm column of 'Amberlite *IR*-120', pyridine form. Each 1 l. of water and 0·2 molar pyridine was passed through the column and a fraction of the eluate (between 900 and 1,720 ml.) was collected and evaporated to a dried residue which contained β-alanine and β-aminoisobutyric acid. The residue was applied to a 6 × 75 cm column of 'Amberlite *IR*-120', equilibrated with a mixture of pyridine, acetic acid and water (2:8:123) and chromatographed with 10·5 l. of the same buffer followed by a mixture of pyridine, acetic acid and water (14 : 40 : 615). The eluate (between 12 and 13·2 l.) was evaporated to dryness *in vacuo*, and the residue was crystallized from aqueous ethanol to give 157 mg of a crude product.

It was further treated with charcoal and recrystallized twice from aqueous ethanol to obtain 93 mg of colourless plates, melting point 189°–192° C (synthetic 191°–192·5° C).

Found C: 40·35%, H: 8·04%, N: 15·33%
Calculated for $C_3H_7NO_2$ C: 40·44%, H: 7·92%, N: 15·72%

The results summarized in Table 1 suggest that β-alaninuria is a common phenomenon among patients suffering from tuberculosis of various tissues and is not specifically related to affections of pulmonary tissue. Other amino-acids were measured with an amino-acid analyser in urine specimens from three patients with lung tuberculosis and three normal subjects. β-Aminoisobutyric acid (two-fold) and glycine (two-fold) also increased in addition to β-alanine (ten-fold), but amounts of other amino-acids remained normal. The increase in the first two amino-acids cannot be taken as significant because only a small number of specimens were examined and because the concentration of these two amino-acids in human urine varies widely between individuals because of genetic influences.

Table 1. CONCENTRATION OF β-ALANINE IN THE URINE OF PATIENTS WITH VARIOUS DISEASES

Subject	No. of cases	Age	Amount of β-alanine (μg/mg of creatinine) Mean value	Range	No. of cases of more than 8 μg/mg creatinine
Normal	51	14–72	1·4	0–8	0
Pulmonary tuberculosis	141	16–72	22	0–130	94
Tuberculous arthritis and ostitis	16	13–67	19	0–49	13
Tuberculosis of cervical lymph nodes	17	14–65	11	0–38	4
Pulmonary cancer	32	37–73	1·1	0–8	0

Liver diseases	12	18–40	0·8	0–5	0
Renal diseases	11	7–62	2·2	0–8	0
Others	26	8–72	0·9	0–8	0

Table 2. CONCENTRATION OF β-ALANINE IN URINE AND PLASMA

Subject	β-Alanine in urine (μg/mg of creatinine)	β-Alanine in plasma (μg/ml.)
Normal	1	0·27
	3	0·45
	2	0·40
Pulmonary tuberculosis	20	0·67
	21	0·78

Table 3. CONCENTRATION OF β-ALANINE IN LUNG TISSUE

Subject	β-Alanine in urine (μg/mg of creatinine)	Pathological tissue (μg/g of wet tissue)	Normal tissue (μg/g of wet tissue)
Pulmonary tuberculosis	49	9	14
Pulmonary tuberculosis	35	11	—
Bronchiectasis (not tuberculous)	1	14	14

Concentration of β-alanine in plasma was determined with an amino-acid analyser after passing an extract of plasma with trichloroacetic acid through a column of 'Amberlite *IR*-120', H^+ form, followed by washing with water and elution with 1 molar pyridine. The result is shown in Table 2, which shows an increased concentration of β-alanine in plasma from patients with β-alaninuria. Concentrations of β-alanine in extracts with trichloroacetic acid of the lung tissue were low both in apparently normal and pathological tissues as Table 3 shows, suggesting that β-alaninuria in patients with tuberculosis is not the result of increased production of β-alanine in the pathological lesion of the lung. To determine the extent of breakdown of β-alanine, 500 mg of β-alanine was administered orally to two patients with pulmonary tuberculosis who had excreted moderately large amounts of β-alanine and two normal subjects. Urine specimens were collected every hour for 12 h. When administered to the patients the amount of β-alanine in urine increased significantly and returned to the original concentration in 8 h. β-Alanine increased during this period by 60 and 100 mg in the two patients, and in normal subjects by 18 and 10 mg, respectively. This suggests a disturbed metabolism of β-alanine in the patients with tuberculosis.

Immune Response of Rabbits during Short Term Exposure to High Altitude

THERE is evidence that both a hypoxic stimulus, such as high altitude exposure, and an immunogenic stimulus act by inducing cell differentiation of some pluripotential stem cell[1,2]. It may or may not be the same pluripotential stem cell on which these stimuli act, the former causing differentiation into erythrocytes, the latter into lymphoid cells which produce antibody (Ab). Recent results have shown that a hypoxic stimulus also increases the immune response of animals exposed to chronic high altitude[3-5]. This suggests that perhaps there is a synergistic action between the two stimuli on a common target cell or organ. If cell differentiation is involved in the synergistic action, then two simultaneous stimuli of equal duration applied to undifferentiated stem cells would be expected to be more effective in producing a demonstrable increase in the immune response than separate, successive applications of the two stimuli.

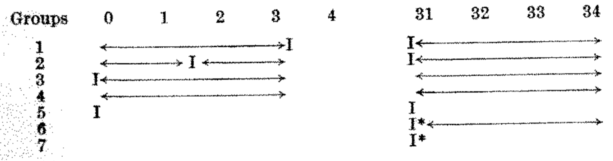
To test this assumption we subjected rabbits to a short time high altitude stress (72–82 h, which approximately corresponded with the time needed for the expression of the primary immune response) and to an immunogenic stimulus simultaneously or successively. The conditions of these experiments were very different from those involving exposure to chronic high altitude[3-5], and consequently their interpretation may be different.

New Zealand white male rabbits, weighing between 2·1 and 2·6 kg, were used in the experiments. The rabbits were immunized with crystalline ovotransferrin (Sigma). One mg of this protein in 0·1 ml. of saline, emulsified with an equal volume of Freund's complete adjuvant, was injected into each foot pad of the rabbits, and another 1 mg was injected intraperitoneally. After 31 days, 0·5 mg of ovotransferrin, emulsified with Freund's adjuvant, was injected into the left hind foot pad of the rabbit. Some rabbits were immunized with a single 0·2 ml. injection of packed sheep erythrocytes into their right foot pads and with ovotransferrin, as described, into their left foot pads. These rabbits were used in determining the number of Ab forming cells by the haemolytic plaque technique. In these conditions of immunization the popliteal lymph node is stimulated primarily[6].

The rabbits were exposed to a simulated 20,000 ft. (350 mm of mercury) altitude in a 30 ft. long, 10 ft. diameter, double pressure lock chamber (Pittsburgh DesMoines Steel Company). The pressure was maintained within ± 20 mm of mercury throughout the experiments. The temperature was kept at a constant 74° F, and the relative humidity between 45 and 60 per cent. (During the early stages of this work the malfunctioning of the air conditioning system caused a rise in temperature up to 82° F and in humidity up to 92–96 per cent.) The experimental design is shown in Table 1.

Serum antibody titre was determined by the passive haemagglutination test of Stavitsky and Arquilla[7]. Ovotransferrin (2 mg) in 0·2 ml. of 0·1 molar phosphate buffer, *p*H 7·3, was first added to 0·05 ml. of packed sheep erythrocytes, then 0·5 ml. of bis-diazotized benzidine (BDB, 0·36 mg/ml.) diluted fifteen times was added for optimal conjugation. Less ovotransferrin resulted in spontaneous haemagglutination, whereas less BDB decreased the specific haemagglutination titre.

Table 1. EXPERIMENTAL DESIGN



I, Time of injection with ovotransferrin as described in the text.

I*, Immunization with both ovotransferrin and sheep erythrocytes. The horizontal arrows indicate the duration of exposure to simulated altitude of 20,000 ft. in the chamber. Groups 1–5 contained seven rabbits each, groups 6 and 7 contained four each. The rabbits were always immunized outside the chamber either immediately preceding or immediately following exposure in the chamber.

The haemolytic plaque test was carried out as described by Jerne and Nordin[8]. The right popliteal lymph node was removed from the rabbits 5 days after immunization with sheep erythrocytes. The haemolytic plaque forming lymph node cells were observed and counted under a Bausch and Lomb stereoscopic microscope.

Haematocrit and haemoglobin assays were taken throughout the experiments to act as a routine check on the effect of high altitude on the number of erythrocytes in the circulating blood. To have some measure of erythropoietic activity we also measured the activity of delta-amino-laevulinic acid dehydrase (DALAD) in the spleen and in the femoral bone marrow by the technique of Mauzerall and Granick[13]. DALAD is the key enzyme in haemoglobin biosynthesis and it may be an excellent indicator of erythropoietic stimulus and erythropoietic activity[14].

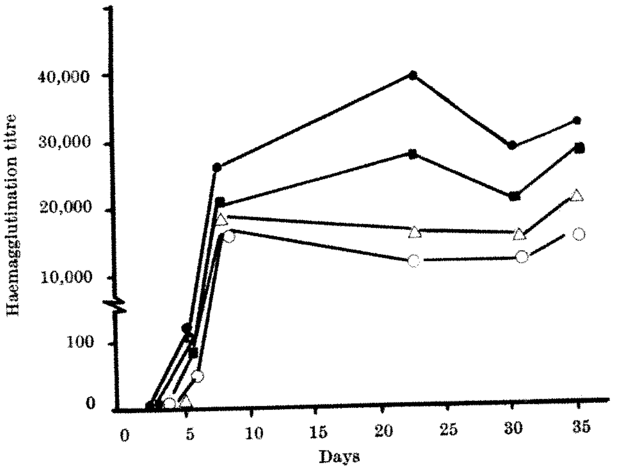


Fig. 1. Haemagglutination mean titre in immunized rabbits and rabbits exposed to altitude. The mean titres were determined from three assays for each rabbit (3 × 7 = 21 samples). ○, Group 1; ■, group 2; ●, group 3; △, group 5.

We have found that the humoral antibody production was stimulated significantly in the altitude stressed rabbits only if the immunogenic stimulus coincided with the altitude stress (Fig. 1). Only group 3 rabbits had a significantly increased haemagglutinin titre compared with the ground control (group 5). If immunization took place 40 h after exposure to altitude (group 2), there was a slight increase in the haemagglutination titre, but if immunization took place after 82 h altitude exposure (group 1) the immune response was essentially the same as in the ground control immunized rabbits.

The cellular antibody response corroborated these findings. Only rabbits immunized and exposed to altitude simultaneously (group 6) had an elevated haemolytic plaque count, as is shown in Table 2. The rabbits in groups 6 and 7 were immunized with two immunogens, sheep erythrocytes and ovotransferrin. The good correspondence between the haemolytic plaque count (indicating antibody producing cells against sheep erythro-

Table 2. EARLY ANTIBODY RESPONSE OF ALTITUDE STRESSED AND NORMAL RABBITS IMMUNIZED WITH SHEEP ERYTHROCYTES AND OVOTRANSFERRIN

Groups	No. of antibody forming cells in 0·2 ml. of popliteal lymph node suspension*	Haemagglutinating titres against ovotransferrin at 6 days
6	$\bar{x} = 216 \pm 24{\cdot}0$	$\bar{x} = 120$
7	$\bar{x} = 141 \pm 19{\cdot}2$	$\bar{x} = 40$

* The weight of the popliteal lymph nodes was approximately equal in both groups, 0·18–0·20 g, almost twice that of the lymph nodes from non-immunized rabbits (0·09–0·12 g).

cytes) and the serum haemagglutin titre against ovotransferrin suggest that the observed effect of high altitude is independent of the immunogen used.

It appears that the increased immune response was compensated by a decrease in haematocrit and haemoglobin levels and in the activity of DALAD in the spleen and bone marrow. As Fig. 2 shows, the haematocrit and haemoglobin levels of group 3 rabbits (first immunized, then exposed immediately to altitude) did not rise as much as those of altitude control group 4. When the rabbits were exposed again to altitude without re-immunization about a month after the first exposure, all groups showed an approximately equal erythropoietic response. This observation shows that the immunogenic stimulus was responsible for the altered erythropoietic response during the first exposure of the rabbits in group 3. It is interesting to note in Fig. 2 that the increase in haemoglobin and haematocrit levels was significantly smaller in the second short term exposure to high altitude than in the first one.

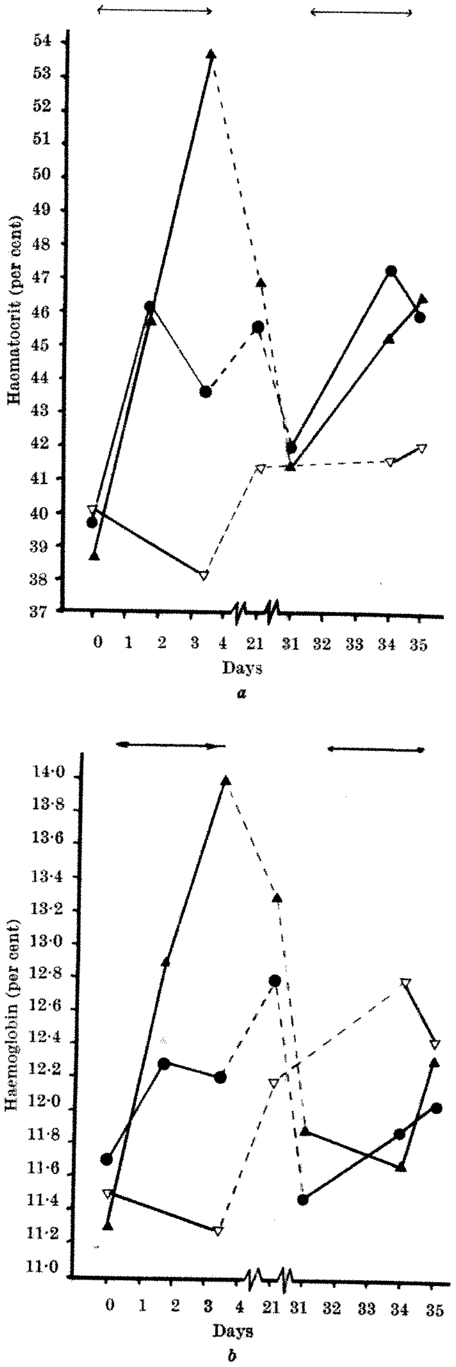

Fig. 2. Haematocrit (*a*) and haemoglobin (*b*) level of altitude stressed rabbits with simultaneous immunization. The horizontal bars indicate the time the rabbits spent in the chamber. The data shown in this and subsequent figures are mean values. The standard deviation varied between ±0·2–2·4, P ≥0·05. For experimental group description refer to Table 1. ●, Group 3; ▲, group 4; ▽, group 5.

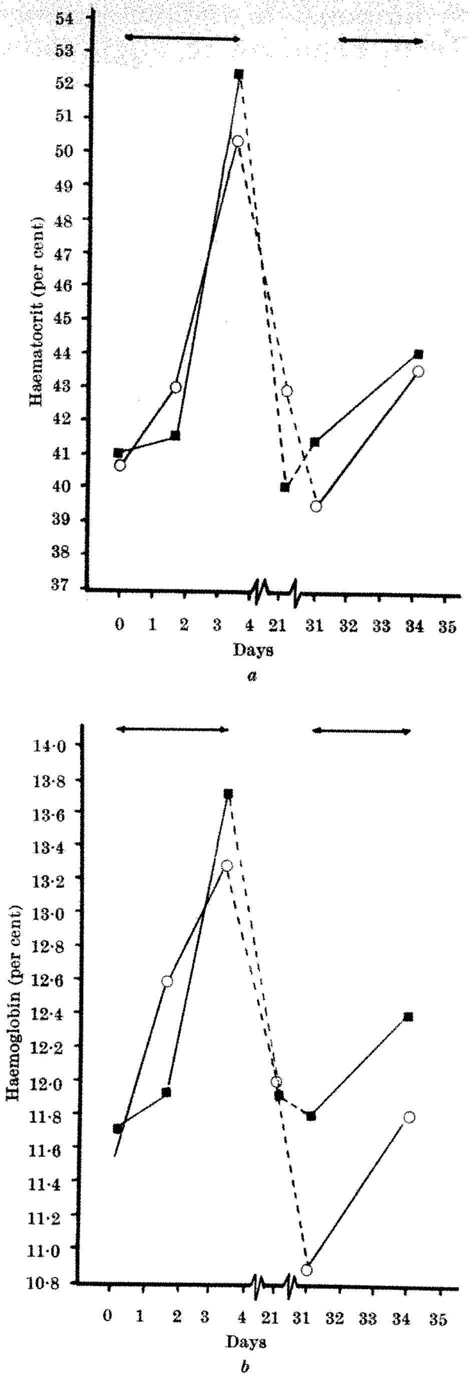

Fig. 3. Haematocrit (*a*) and haemoglobin (*b*) values of altitude stressed rabbits with delayed immunization. ○, Group 1; ■, group 2.

When the two stimuli were applied successively as in groups 1 and 2, the haematocrit and haemoglobin levels were essentially the same as in altitude control group 4 (Fig. 3). The immunogenic stimulus alone (ground control, group 5) did not have any effect on these parameters.

The activity of DALAD in the spleen was significantly lower in group 3 than in the other altitude stressed groups (groups 1, 2 and 4). The same but less pronounced results were obtained with bone marrow (Table 3).

Table 3. ACTIVITY OF DALAD IN THE SPLEEN AND FEMORAL MARROW OF IMMUNIZED AND ALTITUDE EXPOSED RABBITS

Group	Activity of DALAD Spleen	 Bone marrow
1	0·71 ± 0·05	0·56 ± 0·05
2	0·68 ± 0·007	0·49 ± 0·05
3	0·57 ± 0·03	0·46 ± 0·05
4	0·73 ± 0·04	0·55 ± 0·04
5	0·45 ± 0·04	0·38 ± 0·04

Activity of DALAD is expressed as porphobilinogen formed in μmole/g of wet tissue in 1·5 h of incubation. For this assay three extra rabbits were included in groups 1–5; these rabbits were killed on day 5 and the spleens or femoral marrow were assayed after thorough homogenization.

The results are consistent with the assumption that the synergistic effect of the hypoxic and immunogenic stimuli is caused by their simultaneous action on a common target cell, which may be a pluripotential stem cell. When the altitude stress was applied before immunization, the immune response followed the same pattern as if the two stimuli were applied separately. Our data indicate that once the triggering event of the cell differentiation has taken place (in our case there seems to be a critical time within approximately 40 h) the subsequent new stimulus acts independently of the first one. The increased number of Ab producing cells found in group 6 rabbits strongly supports the assumption that the synergistic action of the two stimuli was an increase in the rate of cell differentiation in the lymphoid line.

It is interesting to note that the secondary, anamnestic, immune response was not influenced by high altitude exposure, even if the two stimuli were applied simultaneously (Fig. 1). This observation is in agreement with the often expressed but widely debated opinion that the secondary immune response acts on already differentiated cells, but does not cause stem cell differentiation[12].

The behaviour of the haematocrit and haemoglobin levels and especially the activity of DALAD indicates that a carefully controlled homoeostatic balance must be maintained in the system. The increase in the immune response took place at the expense of processes controlling the level of erythrocytes in the circulating blood. The decrease in the activity of DALAD in the spleen and bone marrow at the same time as the number of Ab producing cells increased in the lymph node suggests that perhaps the cell differentiation of a common pluripotential stem cell was directed into lymphoid cell production. If such a stem cell would have the potential of differentiating into either erythrocytes or lymphocytes, and we could assume that it is available in a limited supply, it would be understandable that when a large proportion of these stem cells is committed for lymphocytes a smaller proportion would be available for differentiation into erythrocytes. A tentative model for this hypothesis is offered in Fig. 4, which may be in accordance with present theories on stem cell differentiation[9–11]. This model may be a useful starting point for detailed investigations of processes of cell differentiation involved in erythropoietic and immunogenic stimuli. The possibility that the hypoxic and immunogenic stimuli may affect the same pluripotential stem cell makes the simultaneous study of altitude stress and immune response particularly interesting.

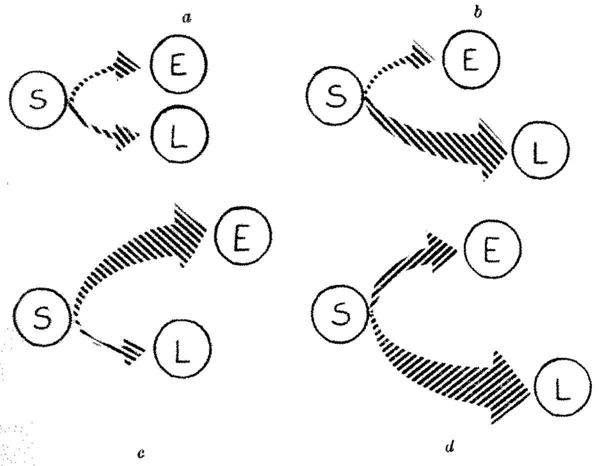

Fig. 4. Scheme for cell differentiation in altitude stressed and immunized rabbits. *S*, Stem cell; *E*, erythroid cell line; and *L*, lymphoid cell line. The arrows illustrate the rate of cell differentiation in the indicated direction. *a*, Normal control; *b*, immunized; *c*, altitude stressed; *d*, immunized and altitude stressed.

CYTOLOGY

Growth and Morphogenesis of Asparagus Cells cultured *in vitro*

SINCE Steward[1] demonstrated the totipotency of plant cells the morphogenesis of plant tissues cultured *in vitro* has often been investigated. So far, embryoid formation has been found only in dicotyledons. We report here the production of embryoids and their subsequent development into complete plants in a culture of a monocotyledon, *Asparagus officinalis* L.

Asparagus callus, derived from hypocotyls of sterile seedlings, was grown on the basal medium developed by Linsmaier and Skoog[2], with the addition of 2,4-dichlorophenoxyacetic acid (2,4-D) and kinetin. The cultures were kept in a growth room maintained at 25° ± 2° C under continuous illumination from Philips TL 4010/33 tubes. The light intensity at the level of the culture vessels was about 40 mcal/cm^2/sec.

In a number of growth experiments on solid agar media, the callus was found to grow most rapidly with hormone concentrations of 1 mg 2,4-D/l. and 0·315 mg kinetin/l. The green callus proliferated vigorously on this medium with occasional organ formation. When both growth substances were omitted from the medium, large numbers of shoots formed with few or no roots. Both growth substances, when added either singly or in combination with a relatively low concentration of the other substance, were able to suppress organ formation without seriously impairing callus growth.

For a more detailed investigation we decided to use suspension cultures. The tissue was multiplied in 100 ml. Erlenmeyer flasks rotated at 100 r.p.m. After about

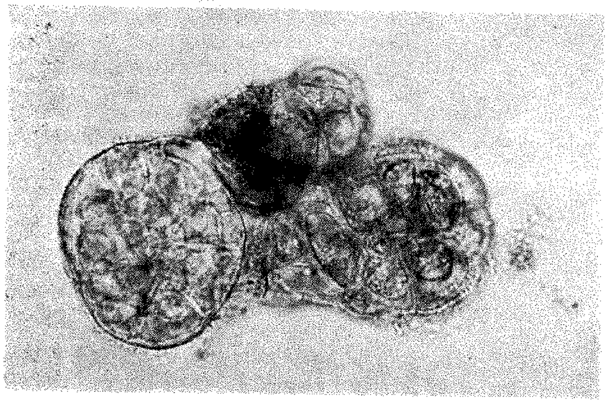

Fig. 1. Globular asparagus embryoids grown in suspension culture (× 480).

2 weeks of growth the larger clumps were removed by sieving through a 2 mm stainless steel mesh. After centrifugation at 2,000 r.p.m. the old medium was discarded and the pellet resuspended in fresh basal medium. The resulting cell suspension was then equally divided into 35 ml. aliquots in 100 ml. flasks by means of a dispensing apparatus fitted with a magnetic stirrer. Finally, the test compounds were added with a sterile syringe. The wet weight increase and morphogenetic behaviour of each culture were then recorded over a growth period of about two weeks.

Several such experiments were carried out, and the effect on cell behaviour of 2,4-D concentrations of 0, 0·01, 0·1, 0·315, 1 and 3·15 mg/l. in combination with 0, 0·1, 0·315 and 1 mg/l. of kinetin was studied. As with the solid culture, a combination of 0·315 mg of kinetin and 1 mg of 2,4-D/l. of medium was found to be optimal for callus growth. The average length of the cells was about 100μ.

Although, initially, the callus cells proliferated well in this medium, the growth pattern changed after a short time. Large numbers of small, round, densely plasmatic cells appeared, and these showed a marked tendency to aggregate. Simultaneously, small nodules, resembling young globular embryoids varying in size from 50 to 200μ, appeared in the cultures.

Several experiments showed that with decreasing concentrations of 2,4-D, callus growth in the form of large vacuolated cells was reduced, with a simultaneous reduction in average cell size. Cell clumping and the formation of globular embryoids increased with decreasing 2,4-D in the media. Furthermore, the embryoid, once formed, grew faster with smaller quantities of 2,4-D.

Although kinetin was beneficial for embryogenesis and growth of young embryoids, the best result was obtained with a low concentration (0·1 mg/l.). Larger amounts frequently induced dedifferentiation of the embryoids.

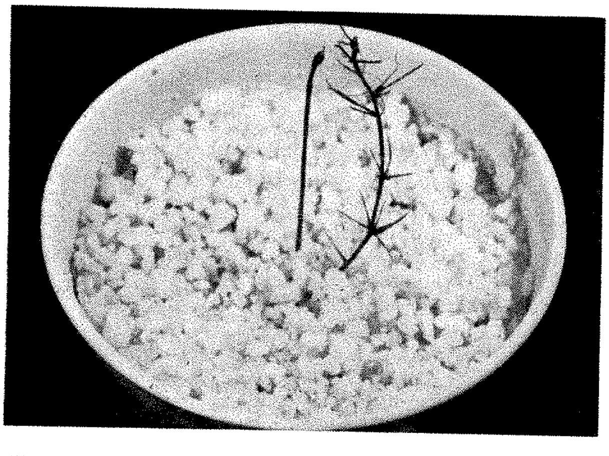

Fig. 2. Young asparagus plantlets grown from callus culture. Stem length about 4 cm.

Once globular embryoids had formed, they developed according to the pattern of normal embryos *in vivo*. They elongated to form a banana-shaped structure, up to 2 mm in length. The first sign of polarity consisted of a one-sided increase in chlorophyll content and gradually the other end elongated to form a radicle.

A striking difference found between normal embryos formed *in vivo* and embryoids formed *in vitro* was the often disproportionate elongation of the stem and radicle ends in comparison with the relatively slow development of the growing points. In order to investigate whether an increase in the osmotic value of the medium would delay "germination" and allow the embryoids to develop more slowly into more balanced seedlings, some experiments were carried out with sucrose concentrations of 2, 4, 6, 8 and 10 per cent. Raising the osmotic value did reduce premature germination, but the percentage of abnormal embryoids increased with increasing amounts of sucrose.

Only small embryoids (not more than about 2 mm in length) grew into normal plantlets after transfer to solid media. When left in the suspension culture beyond the 2 mm stage, the embryoids dedifferentiated at the apex and remained abnormal after transfer. The best initial growth of the transferred embryoids was obtained on a solid medium of the same composition as that of the suspension culture. When transferred at the right stage of development to solid media, the embryoids soon attained geotropic orientation.

When left on this medium, however, the plantlets often dedifferentiated again. Transfer to a simpler medium (Difco orchid agar) within 1 week was therefore necessary. After some weeks the plantlets could be transferred to vermiculite or soil. With this succession of media we were able to grow completely healthy normal plants from undifferentiated callus cells. Among these plantlets were normal diploids as well as some tetraploids. These results indicate that in monocotyledons as well as in dicotyledons differentiation is a natural property of the cells, which cannot manifest itself in callus growth.

We have carried out similar experiments with tissue of the wild carrot *Daucus carota*, and have been able to confirm the results reported by Halperin[3,4] for this tissue. So far, the differences in reaction to environmental conditions with respect to morphogenesis have been largely quantitative for the two species.

GENETICS

Absence of Thymus in a Mouse Mutant

THE mouse mutant "nude" has been described by Flanagan[1]. It is an autosomal recessive. The homozygotes, *nu nu*, are hairless and their growth is retarded. More than half die before weaning and none survives for as long as 25 weeks. Other parts of the syndrome were: sulphydryl group deficiency and abnormal keratinization of hair follicles, and necrosis of the liver, associated with *Toxoplasma gondii* infection. No single primary defect of development responsible for these pleiotropic effects could be suggested.

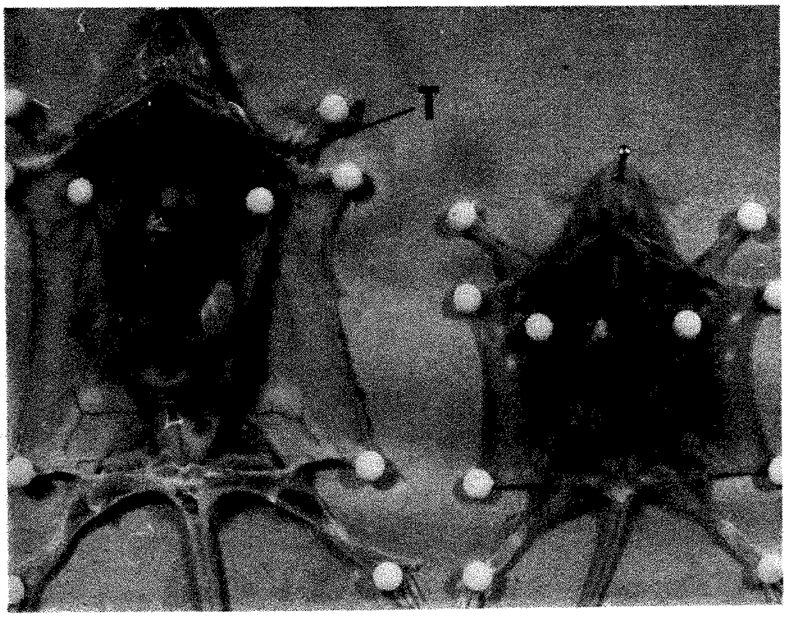

Fig. 1. Dissected normal (left) and homozygote nude (right) sibs. Note the absence of the thymus (T) from the latter.

A re-investigation of the mutation has yielded the following results. No thymus can be found in the homozygotes, while in all normal phenotypes (homozygote wild type or heterozygotes) the organ is normally developed (Fig. 1). The absence of the thymus was confirmed for both sexes and for all ages.

Counts of blood leucocytes were made on groups of various ages (Table 1). In homozygote *nu nu*, counts are extremely low. In normal phenotypes, counts are either about four times greater, or as low as in the nude phenotypes. The low counts are given by the heterozygotes, as confirmed by those cases where the samples were collected from known (genetically tested) heterozygotes. Thus leucocyte counts can serve as a test for the detection of heterozygote carriers.

Necrosis of the liver was not observed in my stock carrying the mutation. Adult homozygotes often showed yellow spots or areas on the liver surface. Histologically, some of these livers exhibited foci of leucocyte infiltration. In some cases, these foci were very extensive, and the organ appeared as a chimaera of liver parenchyma and lymph node (Fig. 2), suggesting virus infection.

It is possible that the lack, or agenesia, of thymus may be the primary defect of development in this mutation. The exact chain of causation leading to other defects remains to be investigated.

I thank Dr D. S. Falconer and Dr S. P. Flanagan for a breeding nucleus of the mutant and for helpful discussions.

PHYSIOLOGY

Drinking Rates and Gill Ionic Turnover in relation to External Salinities in the Eel

SMITH[1] has shown that seawater teleosts maintain their water balance by drinking water and eliminating the divalent ions renally and the monovalent ions extrarenally. Keys[2] demonstrated that the extra-renal route of excretion is most probably the gills. On the other hand, Smith[3] and Krogh[4] say that "the freshwater teleost apparently does not drink water but absorbs it through the oral membranes or perhaps through the gills". This statement has been challenged by several authors[5,6], but no quantitative evaluation of the drinking rate was attempted.

Recently, the use of radioactive tracers which make possible dynamic studies of salt balance has shown that the salt fluxes were much greater in seawater than in brackish or fresh water[7-15]. Motais and Maetz[11,12] showed by simultaneous measurements of the drinking rates and ionic turnover of *Platichthys* and *Serranus*, that only 10–20 per cent of the influx could be accounted for by salt swallowed. The rest enters by the body surface, presumably through the gills. Similar observations were made on *Fundulus heteroclitus*[13,14] and *Xiphister atropurpureus*[15]. Furthermore, for these species, drinking was confirmed and measured quantitatively in the freshwater and brackish water individuals.

In our investigation of *Anguilla anguilla*, ^{131}I-phenol red permitted the evaluation of the drinking rates in animals adapted either to freshwater, seawater or double strength seawater. Fifty yellow eels were used (body weight, 80–225 g; mean 150 g). The animals were adapted to the external media[16] for at least a week at an uncontrolled temperature (16°–24° C). Drinking rates were measured at 20° C using fishes which had been kept for at least 3 days before the experiment in constant temperature close-circuit tanks. This was to avoid shock effects. A sample (1 ml.) of an aqueous phenol red solution labelled with iodine-131 (3 mg and 0·6 mc./ml.) was added to the 15 l. tank. After 2 h, the fish were rapidly transferred into an inactive medium containing anaesthetic (MS 222, Sandoz). A blood sample was drawn from the caudal vein, the peritoneal cavity was opened and the gut removed, care being taken not to lose any gut fluid. The total radioactivity of the gut (R_g in c.p.m.) was measured in a well-type γ-counter and compared with duplicate samples of external fluid (r_e in c.p.m./ml.) and plasma (r_p in c.p.m./ml.). After these short-term experiments, the hind gut contains relatively much less radioactivity than the stomach and anterior intestine. Error caused by anal loss of gut fluid can therefore be neglected and tying off the anus as recommended by Smith[1] is unnecessary. The drinking rate (ml./h/100 g) was calculated from the following equation

$$\text{drinking rate} = \frac{(R_g - C)100}{r_e . W_f . t}$$

W_f is the body weight of the animal in grams, and t is the duration of the experiment in hours—that is, 2 h. C is a correction factor (in c.p.m.) taking into account the radioactivity of the extracellular fluids contained in the gut and estimated to be 30 per cent of the gut volume (W_g in ml.). This correction was necessary because a certain amount of radioactivity was found in the plasma which could not possibly have originated from a leakage of phenol red through the gut wall. C was estimated to be equal to $0{\cdot}3\ W_g . r_p$. In any case, the correction amounts to less than 5 per cent of R_g. Several control experiments were carried out to detect the nature and origin of this radioactivity. The possibility of any marked release of iodide caused by radiolysis could be excluded, because electrophoresis of the phenol red solution produced no iodide spot. Furthermore, no accumulation of radioactivity was observed in the thyroid tissue of the fish. On the other hand, control experiments were run by the *in vivo* gut perfusion technique described previously[16]. They showed that the amount of phenol red passing through the gut wall amounts to a maximum of 2 per cent of the dye content of the gut each hour (unpublished work of E. Skadhauge).

The drinking rates observed (right side of Fig. 1) were 135 ± 27·7 µl./h/100 g (mean and standard error of the mean for $n = 17$) for the freshwater eels, 325 ± 33·5 ($n = 12$) for the seawater animals and 802 ± 182 ($n = 5$) for the fishes adapted to double strength seawater. The increase in the amount of water swallowed with increasing external salinities is very significant ($P < 0{\cdot}01$). Drinking is therefore confirmed for the freshwater eel, which drinks much less than *Fundulus*[14] and much more than *Xiphister*[15]. The drinking rates found for the seawater eels agree well with the data of Smith[1], recalculated as 277 ± 72·8 µl./100 g/h ($n = 5$).

Sodium turnover rates were measured at 17° C in a close-circuit system after intraperitoneal injection of an isotonic solution of ^{24}NaCl or ^{22}NaCl. The adaptation media were either half strength seawater, seawater (Na concentration, 525 mequiv/l.) or double strength seawater (Na concentration 1,040 mequiv.). On the left of Fig. 1 the calculated values of the fraction of exchangeable sodium renewed in percentage/h are summarized. For the freshwater eels, we used the data of Garcia Romeu and Motais[17]; the observed fluxes for an external sodium concentration of 0·5 mequiv. represent 0·5–1 per cent of the exchangeable sodium each hour. For half strength seawater, the turnover rate was found to be 6·6 ± 0·36 ($n = 5$). The rate of sodium exchange was 27·2 ± 3·54 ($n = 5$) and 61·2 ± 7·92 ($n = 4$) for the eels adapted to seawater and double strength seawater, respectively. This highly significant increase ($P < 0{\cdot}01$) in turnover rate in relation to increasing external salinity confirms and extends to hypersaline media previous observations obtained with other teleosts[18,19].

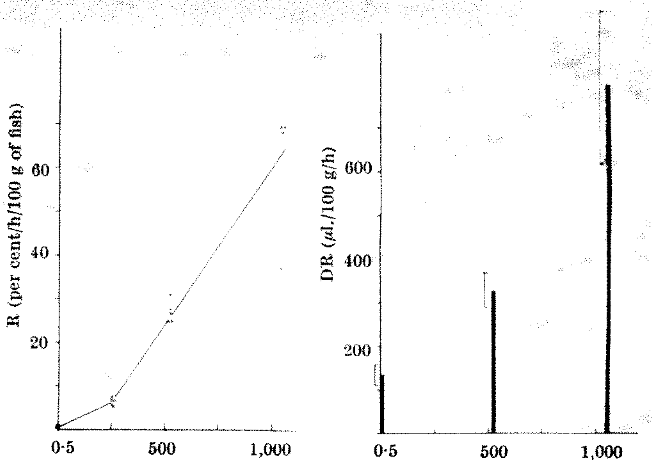

Fig. 1. Left hand side: sodium turnover rates (R) as a function of external concentration of sodium. Right hand side: drinking rate (DR) as a function of external concentration of sodium (standard error of the mean is indicated by brackets).

Both ourselves[16] and Utida *et al.*[20], independently, have shown for the eel that the permeability of the gut to water as well as the ionic absorption capacity of the gut increases with increasing external salinities. It is interesting to compare this capacity with the amount of salt swallowed (or gut influx) and with the total ionic influx as measured isotopically. Such a comparison is given in Table 1 for the sodium ion. It can be seen that the gut absorption capacity exceeds the amount of sodium swallowed except in the animals adapted to double strength seawater. In all media, the gut sodium influx is much less than the total sodium influx.

As expected, with increasing external salinity and an increased osmotic gradient between external and internal media, the rate of drinking increases and compensates for the increased water loss through the body surface. Consequently, the amount of salt absorbed increases and, because the animals remain more or less in a steady state with respect to their sodium balance, more salt is excreted

Table 1. COMPARISON OF TOTAL SODIUM INFLUX, GUT SODIUM ENTRY AND MAXIMAL GUT ABSORPTION CAPACITY FOR EELS ADAPTED TO VARIOUS SALINITIES

Adaptation medium	Total influx	Gut sodium influx	F	Gut absorption capacity	Plasma sodium
Fresh water	21	0·065	0·3	151	130·2 ± 2·43 (25)
Salt water	1,320	170	13·0	332	146·9 ± 2·34 (25)
Double strength seawater	3,550	835	23·5	669	176·0 ± 3·84 (11)

Total influx of fresh water is given in ref. 17. Total influx in seawater and in double strength seawater was calculated from the turnover values and the amount of the exchangeable internal sodium, which is the product of the sodium plasma concentration and the sodium space considered as being 33 per cent of the body weight in all external salinities, as in the flounder[11,12]. Gut absorption capacity is as given in ref. 16. Plasma sodium from gut sodium influx, the amount of sodium swallowed each hour per 100 g is the product of the drinking rate and the external sodium concentration (0·5, 525 and 1,040 mequiv./l. for fresh water, seawater and double strength seawater. All fluxes are given in µequiv./h/100 g. F is the fraction (in per cent) of the gut sodium influx to the total influx. Plasma sodium is given in mequiv./l. (Mean ± *S.E.*, number of experiments given in parentheses.) Some of the data correspond to animals used in gut perfusion experiments.

through the gills. The observed increased turnover rate reflects the increased transport activity of the gills.

One last point needs to be emphasized. While the influx of sodium into the gut is negligible in the freshwater animals, the amount of water swallowed (135 µl./h), which is presumably identical to the amount of water absorbed through the gut, is of the same order of magnitude as the urine flow, 200 µl. according to Butler[21] or 450 µl. according to Sharratt *et al.*[22]. This indicates that the gill osmotic permeability is probably less than previously suspected[23].

We thank Mr Lenkauer and Mr Tanguy for technical assistance. We also thank the Département des Radioéléments de Saclay, which prepared the phenol red solution and checked for the presence of iodide.

Effect of Bromide Ions on Junctional Transmission

The efficacy of bromides as hypnotics or sedatives has long been recognized, but their mode of action is unknown. Many drugs which affect the central nervous system, alcohols and barbiturates, for example, have been shown to influence synaptic activity[1–3] and it seemed likely that bromides might act similarly. The effect of bromide ions on transmission at the neuromuscular junction has therefore been investigated.

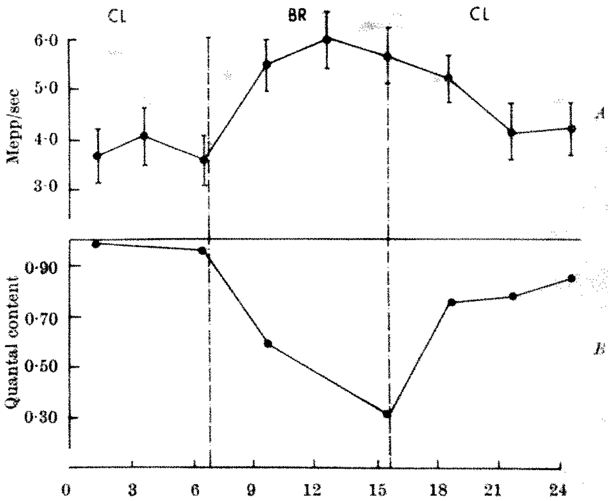

Fig. 1. The effect of bromide ions on neuromuscular transmission. The vertical broken lines denote changes from chloride solution (CL) to bromide solution (BR) and back. *A*, The effect of bromide ions on the frequency of miniature end-plate potentials (mepp/sec; ordinate). Solutions contained 10 mequiv./l. of potassium ions. *B*, The effect of bromide ions on the quantal content of end-plate potentials (for details, see text). Solutions contained 0·7 mequiv./l. of calcium ions, and 6·0 mequiv./l. of magnesium ions.

We have made conventional intracellular recordings at end-plate regions of frog sartorius muscles (*Rana pipiens*). Solutions containing anions other than chloride were made by substituting the sodium salt for sodium chloride in the Ringer solution which contained (mmoles/l.) sodium chloride, 115; potassium chloride, 2·5; calcium chloride, 1·8; and a phosphate buffer (*p*H 7·2). When sodium bromide was substituted for sodium chloride, the frequency and amplitude of miniature end-plate potentials (mepps) increased. The increase in mepp frequency caused by bromide and the decrease in frequency on return to normal Ringer are shown in Fig. 1*A*. In this experiment, solutions contained 10 mequiv./l. of potassium ions to increase the level of mepp frequency for accurate counting. The vertical bars show ± 1 *SEM*. No change in the membrane potential of the muscle was observed during the changes in the concentration of external chloride. The stability of the membrane potential and the increase in the amplitude of the mepp when bromide was substituted for chloride together indicate that bromide decreases the chloride permeability of muscle membrane as has been shown before[4,5]. Increased mepp frequency could be caused by depolarization of the presynaptic membrane from net outward movement of chloride ions which might occur if the nerve terminal were significantly permeable to chloride ions. This possibility was tested by substituting another anion, methylsulphate, for chloride. In such experiments, no increase in the frequency of mepps was seen. Thus bromide ions must have a specific effect on the presynaptic membrane independent of the reduction in the concentration of extracellular chloride. Furthermore, the nerve terminal membrane must have a low permeability to chloride, for large changes in the chloride equilibrium potential apparently do not depolarize the membrane.

The specific effect of bromide on the mechanism of transmitter release is unlike that of calcium or sodium, the ions of which both have greater effects at higher concentrations of potassium[6–8]. When bromide ions were substituted for chloride in solutions containing different concentrations of potassium, the percentage increase in the frequency of mepps was independent of the concentration of potassium. Thus bromide seems to shift to the left the curve relating the frequency of mepps to the concentration of potassium. A similar effect of ions of the lyotropic series on the relationship between tension in frog muscle fibres and potassium concentration has been reported by Hodgkin and Horowicz[9], who suggested that these ions exert their effects by adsorbing onto the outer surface of the muscle membrane and so altering the electric field across it. Because of this analogy another anion of the lyotropic series, nitrate, was substituted for chloride in several experiments. In nitrate solution there was an increase in the frequency and amplitude of mepps similar to that caused by bromide. It was noticed that the muscle membrane was hyperpolarized some 7–9 mV shortly after changing to the nitrate solution and it is possible that in these conditions the muscle membrane was more permeable to nitrate than chloride so that there was a net influx of nitrate causing hyperpolarization.

If bromide and nitrate ions do adsorb to the outside of the nerve terminal the effect on transmitter release should be similar to that caused by membrane depolarization: the frequency of mepps should increase whereas the amount of transmitter released by an action potential should decrease[6,8,10,11]. The effect of these anions on the number of quanta contained in an average end-plate potential (epp quantal content) was therefore investigated. The result of one of these experiments is shown in Fig. 1*B*. The solution contained 0·7 mequiv./l. of calcium and 6 mequiv./l. of magnesium to allow accurate determination of mean quantal contents which were calculated from the formula $\bar{m}$ = ln No. of stimuli/No. of failures (ref. 12). The quantal content in a solution containing 115 mmolar sodium chloride was between 0·9 and 1·0 (Fig. 1*B*). When sodium bromide was substituted for sodium chloride, there was a large decrease in quantal content to approximately 0·3 and the effect can be seen to be almost completely reversible when the preparation was returned to the chloride solution. In solutions containing more calcium and less magnesium, the quantal content of epps, determined from the ratio of the mean amplitudes of epps and mepps, was similarly reduced. A complicating factor in experiments in which the quantal content was derived from measurements of the size of postsynaptic potentials was the slow increase in the resistance of the postsynaptic membrane caused by bromide or nitrate. At junctions blocked by curare the increase in membrane resistance often overwhelmed the fall in quantal content so that epps increased in size. For this reason the "failure" method described here was the method chosen to determine the effect of bromide and nitrate on transmitter release. The potentiating effect of bromide caused by the large increase in "input" resistance of the muscle membrane would not occur at central synapses if, as is generally believed, the postsynaptic membrane has a low chloride permeability. In several experiments, it was found that a bromide concentration as low as 20 mequiv./l. caused a detectable reduction of quantal content.

The effects of bromide and nitrate ions in increasing the frequency of mepps and reducing the quantal content of epps are similar to the effects of presynaptic membrane depolarization[6–8,10,11]. Reduction of the extracellular chloride concentration (methylsulphate substitution), however, does not cause an increase in the frequency of mepps, which indicates that the presynaptic membrane is not significantly depolarized. The effects of bromide and nitrate are not therefore related to changes in the concentration of chloride. The results are consistent with the hypothesis that these anions adsorb to the outer surface of the presynaptic membrane and change the electric field across it in such a way that the efficacy of synaptic transmission is reduced. It seems very likely that the hypnotic and sedative actions of bromides are also related to a pharmacological "presynaptic inhibition" at central synapses.

Physico-chemical Interaction between Adenosine Phosphates and Fibrinogen as a Cause of Platelet Aggregation

Platelets in a citrated or heparinized plasma system adhere to each other to form aggregates in the presence of low concentrations of adenosine diphosphate (ADP)[1]. Adenosine monophosphate (AMP) and adenosine are ineffective in this respect and indeed act as inhibitors of aggregation by ADP[2]. The degree of aggregation depends on the rate of stirring and, consequently, on the collision frequency of the cells, which is an indication that the process causing aggregation occurs at or very close to the platelet surface. Born and Cross[3] and Cross[4] showed that fibrinogen acts as a co-factor for aggregation, and Deykin *et al.*[5] suggested that another plasma protein may also be required. Although Born[6] and Hampton and Mitchell[7] found that ADP is taken up immediately by specific receptors at the surface of the platelets, the mechanism of this type of aggregation is still obscure. Born concluded that "platelet aggregation by ADP comes about through a reaction in which each ADP molecule is briefly involved to produce an alteration in another component of the system, for example in the receptor or in the protein co-factor, without necessarily being altered itself".

Direct cinematographic observation of the influence of ADP upon platelet-rich plasma through a phase-contrast microscope showed that the moment a crystal of ADP was added to the plasma, many fibrin-like particles formed. These particles stuck together and accumulated around platelets and leucocytes. Similar events were seen when ADP was replaced by ATP and AMP. The explanation of these findings is that the solubility of plasma proteins is changed by the addition of AMP, ADP and ATP.

The precipitation of proteins by the addition of salts, which is often accompanied by irreversible denaturation, is a physico-chemical phenomenon and is influenced by the concentration and valency of the added anions. Usually, the higher their valency the lower the concentration at which the protein precipitates. From their molecular structure, the precipitation capacity of AMP, ADP and ATP should be high and should increase in that order. The adenosine phosphates, however, are acidic and their addition to protein solutions also causes a decrease in the *p*H of the solution. At the iso-electric point of a protein its solubility is very low. For nearly all plasma proteins this point lies between *p*H 5·8 and *p*H 3·5, and these values are easily reached in a 10^{-3} molar solution of ADP.

The critical value at which precipitates form was determined for fibrinogen (human and bovine), gamma globulin (human), alpha globulin (human), and albumin (human), by measuring the optical density at 360 mμ of solutions of each of these proteins after the addition of increasing amounts of adenosine phosphates. As soon as a critical concentration was reached there was a sharp rise in the optical density. All proteins were freeze-dried fractions dissolved in a 0·9 per cent NaCl solution. To remove traces of trisodium citrate and other salts, the solutions were dialysed for 24 h against a 0·9 per cent NaCl solution. The protein concentration was made equal to that of normal plasma. The results are shown in Table 1.

It is clear that, if the four proteins, fibrinogen was the most sensitive to low concentrations of AMP, ADP and ATP. The *p*H at the onset of precipitation was 5·0 for all the adenosine phosphates. Proteins with a low iso-electric point (pI) needed higher concentrations of adenosine phosphates, ATP being the most effective. Because of their buffering capacity, compounds such as EDTA and trisodium citrate, which are inhibitors of platelet aggregation, increased the concentration at which precipitates were formed.

We therefore conclude that precipitation was caused chiefly by lowering of the *p*H. The precipitates consisted

of fine particles which stuck together to form aggregates (Fig. 1), and it might be supposed that proteins adsorbed at the platelet cell surface would cause aggregation of the cells themselves if precipitated in the presence of adenosine phosphates. Two arguments seem to conflict with this idea: first, the concentrations of ADP and ATP at which fibrinogen precipitated where higher than those causing platelet aggregation, and AMP does not cause any platelet aggregation at all; and second, calcium or magnesium is required for aggregation.

Concerning the first point, it should be remembered that through their specific adsorption, the "concentration" of nucleotides at the platelet surface may be much greater than that in the solution. Born[6] provided evidence that each platelet possesses about 2×10^5 receptors for adenosine-like molecules, but that the rate of adsorption of adenosine is very different from that of ADP, which is adsorbed immediately. In slow adsorption only a part of the receptors will be occupied. If, however, all receptors are occupied and we also assume that they are equally distributed over the whole surface of the platelet, which has a diameter of 2 to 3μ, the "concentration" at the cell surface would correspond to a concentration in the solution of 5×10^{-3} mole/l. This "surface concentration" is high enough to induce the precipitation of all fibrinogen adsorbed at[8,9] or present near the cell surface.

Concerning the second point, although the role of divalent cations in platelet aggregation is still obscure, it is known that ADP and ATP can bind these ions in equimolar quantities. We have found that precipitates of $CaHPO_4$, $CaCO_3$ and $MgHPO_4$ are rapidly dissolved by the addition of ADP, ATP or EDTA or, less effectively, AMP. This indicates that ADP and ATP formed soluble calcium complexes, and that calcium is chiefly bound by the pyrophosphate groups. There is little reason why these complexes should not be formed in plasma when free calcium ions are available before these are adsorbed by the platelets. This is in accordance with the experiments of Naets[10], who showed that adenosine diphosphate was only adsorbed by the platelet when free calcium was present. It seems justifiable therefore to conclude that the binding of calcium ions to the adenosine phosphates facilitates their adsorption at the negatively charged platelet surface by diminishing the negative charges of the phosphate group without changing the acidic character of the complex.

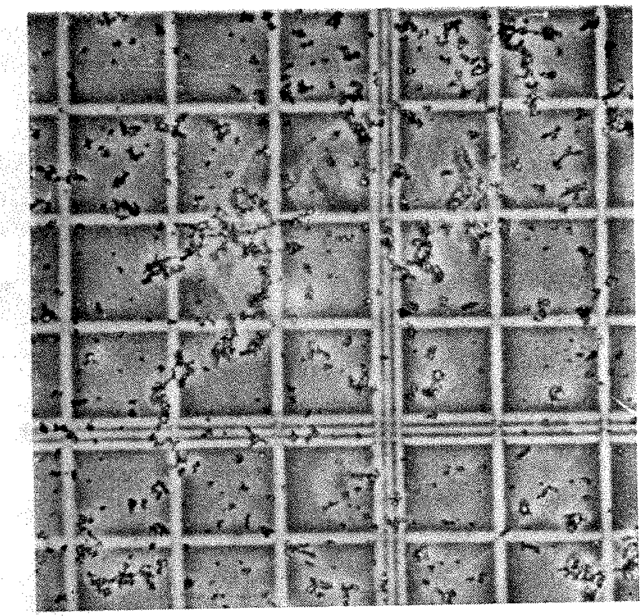

Fig. 1. Precipitation of fibrinogen by $2 \cdot 0 \times 10^{-3}$ molar ADP (phase-contrast photograph).

In summary, we propose that platelet aggregation may be caused by the specific adsorption of an acidic calcium–adenosine phosphate complex causing a lowering of the *p*H near the surface, which is followed by precipitation of proteins, chiefly fibrinogen, giving rise to the formation of bridges between the platelets. This proposal represents an extension of Born's hypothesis. This work forms part of an investigation into chemical aspects of human atherosclerosis and thrombosis, carried out by a research team of the Netherlands Organization of Health Research TNO.

Fibrin Substrate free from both Plasminogen and Fibrin Stabilizing Factor

IN biological systems, the differentiation of plasmin activity from plasminogen activator activity can only be made in a substrate free of plasminogen. Fibrin is probably the natural substrate of plasmin and almost certainly the most sensitive, but it is usually contaminated with plasminogen[1]. Several methods for removing plasminogen from fibrinogen have been described, but in practice these are usually tedious and not always reproducible[2,3].

Most fibrinogen preparations are also contaminated with fibrin stabilizing factor (FSF or factor XIII)[4] and are thus not a suitable substrate for the assay of factor XIII in plasma samples. Methods for removing FSF from fibrinogen preparations are also laborious and not entirely reliable[5,6].

The preparation described and tested here is simple to make, does not require any special apparatus or equipment, is reproducible and seems to be virtually free of both plasminogen and factor XIII.

During an electron microscopic study of the structure of fibrin recently reported by Kay and Cuddigan[7], it was noted that fibrin prepared from a fibrin monomer solu-

Table 1. MONOCHLORACETIC ACID SOLUBILITY OF FIBRIN CLOTS PREPARED BY DILUTION OF FIBRIN MONOMER

0·2 ml. of fibrin monomer (pH 4·8) were added to 0·4 ml. of buffer solution, pH 7·65, containing

1/40 plasma in 0·1 molar borate	0·1 molar borate	1/40 plasma in 0·1 molar borate and 0·025 molar $CaCl_2$	0·1 molar borate and 0·025 molar $CaCl_2$	1/40 plasma in 0·1 molar borate 0·025 molar $CaCl_2$ 0·05 molar cysteine	0·1 molar borate 0·025 molar $CaCl_2$ 0·05 molar cysteine
Soluble	Soluble	Insoluble	Soluble	Insoluble	Soluble

Clots were incubated at 37° C for 18 h before addition of 3 ml. of 1 per cent monochloracetic acid. "Soluble" indicates that the clot dissolved within 15 min of adding solvent; "insoluble" indicates that clot did not dissolve within 2 h of adding solvent.

tion gave a much more clearly defined ultrastructure than did fibrin prepared by directly clotting fibrinogen with thrombin (personal communication from B. J. Cuddigan). This suggested that the fibrin monomer contained less contaminating protein than did the fibrinogen solution. Subsequent studies with fibrin monomer prepared as described here have proved this to be so.

Kabi fibrinogen (human grade L) was dissolved in distilled water to a concentration of 10 mg/ml. This was diluted fifteen- to twenty-fold with 0·85 per cent NaCl, and clotted by the addition of 5 U of bovine thrombin/100 mg of protein. The fibrin was collected onto a glass rod after 90 min of incubation at 37° C and washed in large volumes of 0·85 per cent NaCl, drying carefully with clean filter paper after each wash. After the third wash the fibrin was dissolved in a small quantity of 5 molar urea (1 ml./50 mg of starting material). Complete solution was obtained in 20–30 min and the material could then be reclotted by ten- to fifteen-fold dilution with 0·85 per cent NaCl. This process of clot collection, washing, drying and redissolving was repeated three times until the final urea solution was diluted with an equal volume of 0·05 molar acetate buffer, pH 4·8. The urea was removed by overnight dialysis at 4° C against two changes of acetate buffer. A sample of the final solution (0·1 ml.) clots instantaneously when diluted three- to five-fold with 0·1 molar borate buffer, pH 7·65.

Fibrin monomer prepared in this way was allowed to clot in the presence and absence of calcium, with and without cysteine and with and without added plasma (Table 1). After incubation at 37° C for 18 h, the fibrin in each tube was tested for stabilization by the addition of 1 per cent monochloracetic acid. Clots formed in the presence of plasma and calcium were insoluble in the monochloracetic acid. All the fibrin formed in the absence of plasma and calcium was rapidly soluble in the monochloracetic acid. Cysteine with or without calcium had no effect on solubility.

In another experiment, fibrin formed in the presence and absence of dilute plasma (as a source of plasminogen) was treated with varying concentrations of streptokinase and urokinase (Table 2). Only the clots formed in the presence of plasma lysed during the period of observation.

It seems that fibrin substrate prepared by this method could have considerable advantages when used in assay systems for components of the fibrinolytic mechanism or for the assay of factor XIII. Studies directed towards this end are proceeding and will be published elsewhere.

Inhibition by Adenosine Diphosphate of the Thrombocytopenia induced in Rabbits by Collagen or Thrombin

IT has been reported[1] that in rabbits intravenous infusions or intramuscular injections of adenosine diphosphate (ADP) or adenosine triphosphate (ATP) reduce platelet adhesiveness as measured by glass bead columns. Because collagen and thrombin are implicated in thrombogenesis we thought it worth while to study their thrombocytopenic activities and any changes produced in them by exogenous ADP. In the experiments reported here, ADP markedly inhibited the thrombocytopenia induced by collagen or thrombin.

The rabbits (New Zealand white strain) in these experiments weighed 2·5 to 5·0 kg. They received neither anaesthetics nor anticoagulants.

Collagen extract was prepared as follows. One gram of collagen (tendon-Sigma) was ground by hand for about 20 min in a tissue grinder with three lots of 10 ml. of sterile saline, free from pyrogen. The bulked extracts were centrifuged at about 1,500g for 30 min, when the supernatant was decanted. Additional 1 g lots were processed and all the extracts were combined. The volume was adjusted to give a concentration equivalent to 30 mg of collagen/ml., and the preparation was dispensed in 10 ml. lots into polythene vials and stored at −20° C. Three batches of extract were made, and each was used within

3 weeks. The curves relating dose and thrombocytopenic response, and the effects of ADP on it, were determined for each batch: all three gave similar results, which we have combined in this report.

Thrombin ('Pure', Koch Light) was dissolved in saline to give a solution containing 20 NIH units/ml.

ADP (50 mg/ml. saline) was administered in a dose volume of 1 ml./kg.

Platelet counts were determined electronically[2] on duplicate samples of blood drawn from an ear artery through disposable needles into polystyrene tubes containing dipotassium ethylenediamine tetraacetate.

In the collagen experiments, all the rabbits were given single intravenous injections of extract in doses equivalent to 5, 10, 20, 40 or 60 mg of collagen/kg, and some were injected intramuscularly with ADP (50 mg/kg) 30 min before receiving the collagen. Platelet counts were determined immediately before and 5, 10, 20 and 60 min after administration of collagen. The results for collagen alone are given in Fig. 1. The thrombocytopenia is dose dependent, maximal at about 5 min, and long lasting compared with that after intravenous ADP[1]. The inhibition by ADP of the thrombocytopenia after an injection of 20 mg of collagen/kg is shown in Fig. 2. The antagonism by ADP (measured 5 min after the administration of collagen) to various doses of collagen is indicated in Fig. 3. Clearly ADP markedly inhibits the thrombocytopenic activity of collagen.

The experiment relating to Fig. 2 was repeated with an equimolar dose (60 mg/kg) of ATP. The inhibitory effects of the two nucleotides were almost identical.

We have previously reported that intramuscular administration of ADP (50 mg/kg) to rabbits reduces platelet adhesiveness measured by glass bead columns, the reduction being maximal at 30 min and negligible at 4 h. We thought that it would be of interest in these new experiments to investigate the antagonism by ADP on the thrombocytopenic activity of collagen at various times after the administration of the nucleotide. Pairs of rabbits were injected intramuscularly with ADP (50 mg/kg) and after 0·5, 1, 2 or 4 h they received collagen (40 mg/kg) intravenously. A further pair of rabbits served as controls and received only collagen. Platelet counts were determined immediately before and 5 min after administration of the collagen. The results shown in Fig. 4 indicate parallelism between the reduction in platelet adhesiveness to glass by ADP and its ability to inhibit the effects of collagen *in vivo*.

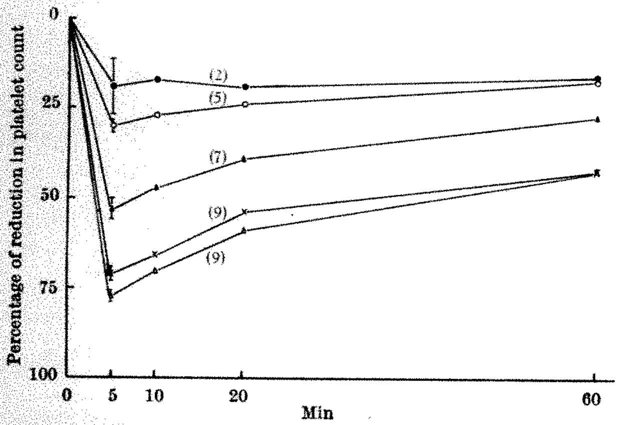

Fig. 1. Reductions in platelet count in rabbits given single intravenous injections of collagen extract. ●, 5 mg/kg; ○, 10 mg/kg; ▲, 20 mg/kg; ×, 40 mg/kg; △, 60 mg/kg. The numbers in brackets refer to the number of rabbits per dose. Vertical lines indicate standard errors.

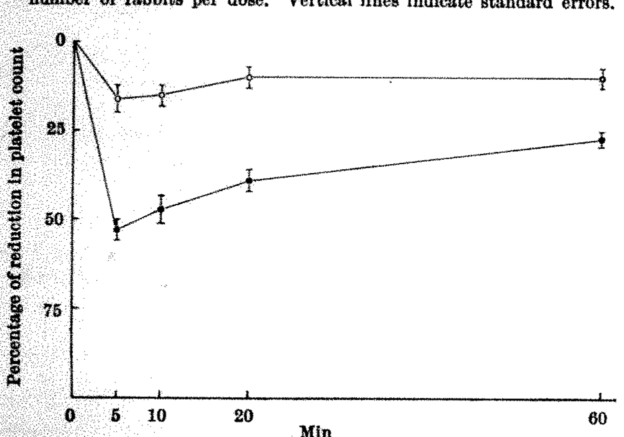

Fig. 2. Inhibition by ADP of the thrombocytopenia induced by collagen in rabbits (seven per group). ●, Collagen 20 mg/kg intravenously; ○, collagen 20 mg/kg intravenously, 30 min after ADP (50 mg/kg intramuscularly). Vertical lines indicate standard errors.

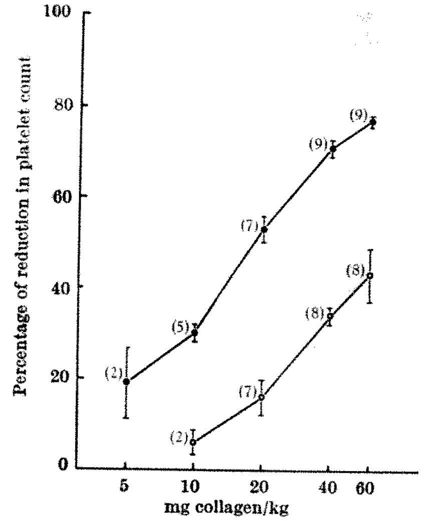

Fig. 3. Inhibition by ADP of the thrombocytopenia measured 5 min after intravenous injections of collagen in rabbits. ●, Collagen only; ○, collagen 30 min after ADP (50 mg/kg intramuscularly). Numbers in brackets refer to the number of experiments. Vertical lines indicate standard errors.

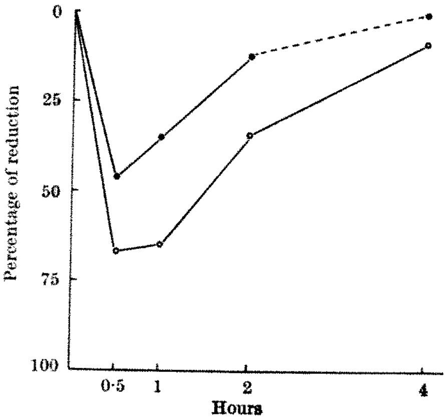

Fig. 4. Reductions by ADP of platelet adhesiveness to glass (○) and of the thrombocytopenic activity of collagen (●). Thrombocytopenia measured 5 min after collagen (40 mg/kg intravenously).

In the thrombin experiments a syringe needle was inserted into an ear artery and about twelve samples of blood were collected with the same needle in the first 2 min after the injection. Thereafter sampling was conducted more leisurely.

The thrombocytopenia after a single intravenous injection of thrombin was pronounced and quick in onset, while the recovery rate was only slightly less than that after ADP. Administering single intravenous injections (20 U/kg) at 10 a.m., 11.30 a.m. and 3 p.m. shows that thrombocytopenia in the same rabbit is reproducible. The three curves relating platelet count with time were almost identical, and the maximum percentage reductions in count were 67, 66 and 61.

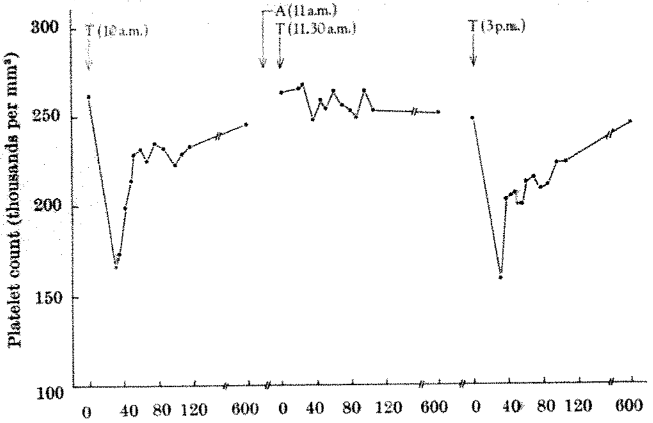

Fig. 5. Thrombocytopenic activities in the same rabbit of thrombin alone or thrombin in the presence of ADP. T, Thrombin 15 U/kg intravenously; A, ADP 50 mg/kg intramuscularly.

The preliminary results with thrombin alone indicated that the response depended on the dose but that the effort necessary to establish a satisfactory dose-response curve would be considerable. It was therefore decided to study possible antagonism by ADP to thrombin using only one dose (15 U/kg) of thrombin.

Antagonism by ADP was studied by giving each of five rabbits single intravenous injections of thrombin (15 U/kg) at 10 a.m., 11.30 a.m. and 3 p.m., and one intramuscular injection of ADP (50 mg/kg) at 11 a.m. A typical result is shown in Fig. 5. The group mean maximum percentage reductions in platelet count after the three doses of thrombin are 43 ± 8, 14 ± 2 and 41 ± 7.

Our earlier experiments indicated that platelets in blood from rabbits injected with ADP had a lowered affinity for glass, and we suggested that if this result truly reflected a decreased tendency for platelets to adhere to damaged intima, then circulating ADP might inhibit thrombogenesis. Our new finding that ADP antagonizes the thrombocytopenia after collagen or thrombin, and the parallelism of this effect with the reduced adhesiveness to glass, strengthen our belief in the relevance of the glass bead test and prompt us to repeat our earlier suggestion of a possible role for ADP or its metabolites in inhibiting thrombogenesis.

We thank Mrs J. A. Fraser and R. A. Khalid for their assistance.

Free Fatty Acid Patterns of Human Maternal Plasma, Perfused Placenta and Umbilical Cord Plasma

CHEN *et al.*[1] have shown that there is a variation in the amount of individual free fatty acids in maternal and cord plasma, suggesting that the foetal free fatty acids do not arise solely from the maternal circulation. The placenta is known to synthesize fatty acids[2] and to use free fatty acids in the formation of phospholipids[3] and cholesterol esters (unpublished work of A. Robertson, H. Sprecher and C. Dobbs). To investigate the inter-relationships of maternal, placental and newborn free fatty acids, we have analysed the free fatty acids from these sources in normal pregnancies.

Maternal and umbilical cord blood was collected at the time of delivery into tubes containing ethylenediaminetetraacetate (EDTA) as an anticoagulant. The placenta was perfused as previously described[3]. Lipids were extracted from the tissues by repeated homogenization with a solution of 2 : 1 chloroform and methanol. The neutral lipids were separated by thin-layer chromatography with a solvent system of petroleum ether, diethyl ether and acetic acid in a ratio of 90 : 20 : 2. The lipid fractions were located by spraying with dichlorofluoroscein and identified by comparison with standards. The free fatty acid band was scraped into glass tubes where the methyl esters were formed by refluxing with 5 per cent H_2SO_4 in methanol. The methyl esters were then extracted with petroleum ether and analysed on an F and M model 810 gas chromatograph[4].

The results of the fatty acid analyses are presented in Table 1. We did not determine the absolute concentrations of the free fatty acids and so we cannot speculate about correlation between the concentrations of maternal and foetal individual free fatty acids. Chen *et al.*[1] suggested that the foetal free fatty acids arise from placental transfer and foetal synthesis. The surprising result in this study is the percentage of arachidonic acid (20 : 4w6) in the placental free fatty acids. This elevation of the relative percentage of arachidonic acid (20 : 4w6) is also reported by Renkonen[5] in his analysis of a single placenta. This may be a result of specific placental transport or metabolism or of foetal influences. In one reported case, that of one liveborn and one stillborn twin, the free fatty acid concentrations of the two distinct placentas were similar[6], suggesting that the placental free fatty acid pool is not derived solely from the foeto-placental circulation. That maternal arachidonic acid (perhaps in the free fatty acid form) may be very specifically transported into the placenta is untested so far, but is suggested by the fact that following delivery the maternal arachidonic acid percentage (of total lipid fatty acids) rises[7]. The fact that this rise does not occur within 2 days of delivery weakens this argument. A valuable study would be the serial measurement of maternal arachidonic acid in the free fatty acid fraction before and after delivery.

Table 1. PERCENTAGES OF FREE FATTY ACIDS

Component	Maternal plasma (6)	Perfused placenta (6)	Umbilical cord plasma (5)
12:0	0·7 + 0·7	1·0 + 0·5	1·3 + 0·6
14:0	5·1 + 2·9	2·0 + 1·1	6·9 + 3·3
16:0	28·4 + 5·7	28·8 + 2·4	37·6 + 2·8
16:1w7	3·7 + 0·6	1·7 + 0·4	3·4 + 1·2
18:0	12·3 + 2·6	20·6 + 2·1	15·8 + 7·3
18:1	38·6 + 7·1	13·4 + 0·6	23·2 + 5·4
18:2	8·0 + 2·6	7·7 + 1·6	7·8 + 3·7
18:3w3	0·8 + 0·9	0·5 + 0·4	0·2 + 0·5
20:3w6	0·8 + 1·0	3·0 + 0·9	0·7 + 0·8
20:4w6	1·5 + 1·1	21·4 + 3·1	2·9 + 1·6

Components are identified by their number of carbon atoms. The number of unsaturated bonds is given after the colon in the first column. Following the w is the carbon number of the first unsaturated bond counting from the methyl end of the molecule. Figures in parentheses are the number of samples. Values are the mean percentage weight plus one standard deviation.

If the placenta gives rise to the accumulation of arachidonic acid within itself, how does this occur ? Arachidonic acid is present in fairly large amounts in lecithin[4], cephalin[4] and cholesterol esters (unpublished work of A. Robertson, H. Sprecher and C. Dobbs) of placental tissue. These materials, however, are either not hydrolysed or hydrolysed at a very low rate by placental tissue[8]. Possibly the placental tissue converts linoleic acid to arachidonic acid. This reaction has not been demonstrated in placental tissue although Kleine[9], from his work on placental triglyceride synthesis, suggests, without proof, that this occurs.

This investigation was supported in part by funds from a public health research grant from the US National Institute of Child Health and Human Development and from a public health research grant from the US National Institute of Arthritis and Metabolic Diseases, and by a

contract with the Ohio Department of Health, Maternal and Child Health Division.

Structure and Function of the Extraneural Sheath in Insects

Treherne and Maddrell[1,2] have described a continuous sheath of tracheal and fat-body cells around the nerve cord of the Phasmid *Carausius*. They have also obtained measurements showing that the fluid between these structures was some 20 mV positive with respect to the haemolymph, seemingly because of a chloride diffusion potential. Their investigation was related to the specialized ionic composition of the haemolymph in *Carausius*, but they concluded that the sheath was not obviously related to the functioning of the nervous system in this environment.

Their conclusion is supported by our observations of a similar sheath around the thoracic nerve cords of *Schistocerca gregaria* (Orthoptera, Acridoidea), *Homorocoryphus nitidulus* (Orthoptera, Tettigoniidae) and *Sphodromantis* sp. (Dictyoptera, Mantoidea) (Fig. 1). In *Schistocerca* the sheath closely resembles that in *Carausius*; in *Sphodromantis* the sheath is very thin and tenuous including only tracheal cells and no fat-body cells. In *Homorocoryphus* intermediate structures occur. This species is found in two forms; one is large, fatty, edible, seasonal and swarm-forming, and the other has opposite characteristics. The extraneural sheaths of these two forms differ in the number and size of fat-body cells, the former having more.

In *Schistocerca*, as in *Carausius*, the sheath is always cellular. In the other two species, the sheath is partially cellular but also has areas which consist of only a very thin basement membrane. This membrane is often so closely appressed to the neural lamella that the boundary between the two can be distinguished only in electron micrographs, but it seems to be continuous in all the connectives that we have seen (Fig. 2). The continuous cellular sheath of *Schistocerca* could presumably function as an active ionic regulator, as postulated for *Carausius*. The mantid and tettigoniid sheaths, on the other hand, have large areas devoid of cytoplasm, and even if the membrane has specific ionic permeabilities, it could function at best as a passive element in ionic regulation, though possibly supplemented by active processes in its cellular portion.

The ionic composition of the haemolymph of these three insects differs widely from each other and from that of *Carausius*. Insects vary widely in this respect; sodium/potassium ratios range from 0·04 to 32·0, nearly three orders of magnitude[3]. *Carausius* (0·8) falls in the middle of this range[2,4,5], *Schistocerca* (6–20, mean 11) near one extreme[6]. *Homorocoryphus* is unlikely to be different from the closely similar *Tettigonia viridissima* with a sodium/potassium ratio of 1·6 (ref. 4). We know of no determinations on mantises, but as carnivores they are likely to equal or exceed *Schistocerca* in the sodium/potassium ratio.

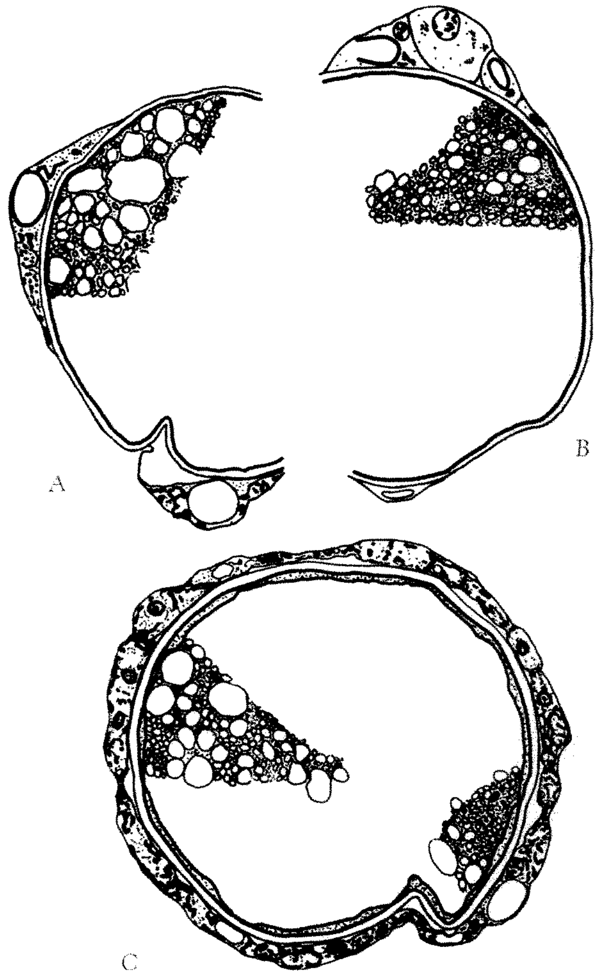

Fig. 1. Partial tracings of sections of nerve cords embedded in 'Araldite' and stained with toluidine blue. Pro-mesothoracic connectives throughout. *A*, *Homorocoryphus*; *B*, *Sphodromantis*; *C*, *Schistocerca*.

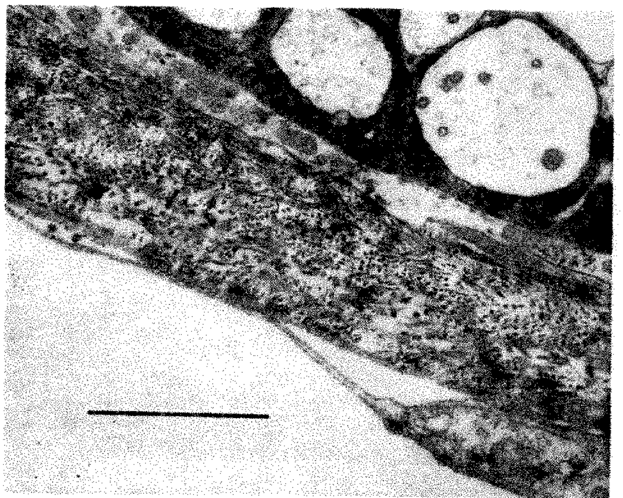

Fig. 2. Electron micrograph of *Homorocoryphus* pro-mesothoracic nerve cord. The neural lamella encloses a very thin perineurium and the axons. Lying on the neural lamella is the end of a fat-body cell, with its membrane prolonged into a thin sheet closely appressed to the surface of the lamella; this sheet is continuous around the connective. Material fixed in buffered osmium tetroxide, stained with uranyl acetate. Scale mark 1μ.

In summary, seemingly homologous sheaths exist around the nerve cords of the orders so far investigated, and vary greatly in morphology. These variations do not correlate with systematic position nor with any obvious feature of the ionic composition of the haemolymph.

BIOLOGY

Detachment of Sea Anemones by Commensal Hermit Crabs and by Mechanical and Electrical Stimuli

The ability of some hermit crabs to detach commensal sea anemones and place them on their shells has interested ecologists and ethologists for many years[1]. Anemones belonging to the genus *Calliactis* are perhaps best known in this respect. Excellent accounts of the behaviour of the Mediterranean hermit crab *Dardanus* (= *Pagurus*) *arrosor* Herbst, towards *C. parasitica* (Couch) have long been available[2,3]. Ross[4] showed that *Pagurus bernhardus* (L.) which lives with *C. parasitica* in the English Channel has no behaviour pattern in relation to the anemone. *C. parasitica* has its own behaviour pattern triggered by a chemical factor in the gastropod shell occupied by the pagurid and the anemone is able to transfer to the shell without help from the crab. Ross and Sutton[5] have also shown that the success of *D. arrosor* in transferring *Calliactis* to its shells depends on the simultaneous occurrence of the anemone's behaviour pattern in response to the shell; they emphasized the co-operative roles of both partners in establishing the association.

Recently we have been able to study the associations between *C. tricolor* Lesueur and *D. venosus* (H. M. Edwards) in the Caribbean, and *C. polypus* Forskal and *D. gemmatus* (H. M. Edwards) at Hawaii. *C. tricolor* showed a response to shells that was similar to *C. parasitica*—that is, it could transfer to shells from other surfaces without the help of *D. venosus*, though the crab was usually an active participant. *C. polypus*, however, seemed to lack the response to shells observed in the other two species. In our experiments, it responded to shells only when its pedal disk was already detached and free from the substratum, though Dr C. E. Cutress reports (personal communication) that he has seen *C. polypus* detaching itself from wood or slate to climb on passing gastropods or empty shells.

In these associations with *C. tricolor* and *C. polypus* it was clear that the behaviour patterns of the crab evoked responses from the anemones which facilitated its detachment from the surface on which it was settled. This happened even when there was no apparent contact with the shell. By moving their appendages on the surface of the anemones, the crabs were able to open up closed *Calliactis* and to induce in them a state of complete relaxation so that the anemone could be lifted or pulled off quite easily.

After studying the behaviour of these pagurids as they detached *Calliactis*, it was possible to simulate the movements of the crabs and to bring about the relaxation and detachment of the anemones without difficulty. Thus tapping the margin of the base of *C. tricolor* with plastic rods (*D. venosus* usually began its activity by using its walking legs and claws in this way) brought about the complete relaxation of the anemone in about 1–2 min and its detachment within 3 min. The most conspicuous feature of the behaviour of the Hawaiian pagurid, *D. gemmatus*, towards *C. polypus* was a gentle prodding of the column with the walking legs and chelipeds. After limited success with metal and plastic rods, we found that the activity of this crab could be mimicked better by applying pressure gently and rhythmically around the column of the anemone with pipe-cleaners attached to the second and third fingers on each hand. These "pseudo-legs" produced a state of complete relaxation in *Calliactis* so that the pedal disk could be freed from a stone or plastic surface (Fig. 1). By this method we were able also to detach *Calliactis* from shells, as *Dardanus* does when it "steals" anemones from other members of its own species.

We noted that these two crabs were applying tactile stimuli to *C. tricolor* and to *C. polypus* at a frequency of about one contact/sec. We therefore also tested the effect of electrical stimuli on *C. polypus* at a frequency of one contact/sec. At the temperatures of the tropical waters in which these anemones live (26°–30° C), stimuli at this frequency do not produce the quick retraction reflex of the staircase type. This occurs when stimuli are applied at frequencies of three contacts/sec and higher[6]. When stimuli were applied and continued at a frequency of one contact/sec, an occasional stimulus at the beginning sometimes caused retraction but these closing movements were short-lived. Within 20–30 sec the anemone usually opened up actively and became relaxed completely in exactly the same way as it did when subjected to the crab's palpations or to the simulated crab behaviour as described. Shortly after *C. polypus* went into this state of relaxation, and with the electrical stimuli continuing, the edge of the pedal disk began to move inwards and within a few seconds the pedal disk became completely detached from the substratum. The time from the beginning of stimulation to the detachment of the anemone rarely exceeded 1 min, which is more rapid than the detachment achieved by the most active crabs.

It is known that stimuli at frequencies below those which cause retraction evoke slow contractions of the column musculature in *C. parasitica*[7]. Such stimuli applied to an isolated basal ring were shown by Ewer[8] to have inhibitory effects and were also shown to cause a local contraction of the pedal edge after a long latent period. Although detachment and relaxation to electric stimuli have been demonstrated only in *C. polypus*, it

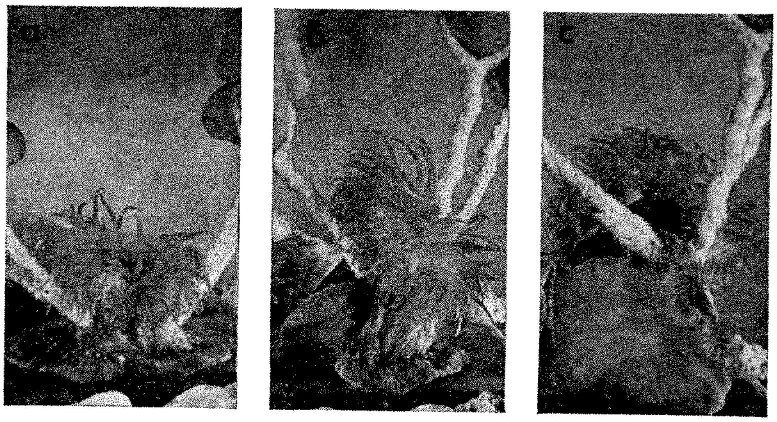

Fig. 1. Release of pedal disk of sea anemone *Calliactis polypus* by mechanical stimuli mimicking stimuli applied by the commensal hermit-crab *Dardanus gemmatus* (pipe-cleaners on fingers used as "pseudo-legs"). *a*, Anemone open and relaxed, stimuli being applied to column, at beginning of treatment; *b*, pedal disk loosening and being lifted by "pseudo-legs"; *c*, exposed pedal disk lifted free after release. (Time between *a* and *c*, 4·5 min.)

would be surprising if *C. tricolor* and *C. parasitica* do not respond in the same way, because the behaviour seems to be based on a direct motor response.

These observations demonstrate new aspects of the mutual interdependence of the behaviour patterns of both partners in the associations between *Calliactis* spp. and *Dardanus* spp. In the association between *D. gemmatus* and *C. polypus* the behaviour of the crab seems to resemble a basic motor mechanism which produces a general inhibition throughout the animal and then induces a local contraction at the base.

Effects of Cercarial Extracts of *Schistosoma mansoni* on HeLa Cells

For many years investigators have suggested that parasite toxins play a part in the pathology of schistosomiasis[1-3]. Unfortunately, no attempts seem to have been made to evaluate the cytotoxic potential of schistosomes *in vitro* until recently. In 1936 and 1937 cercarial extracts of the trematodes *Diplostomum flexicaudum* and *Cryptocotyle lingua* were reported to produce cytopathology in excised tissue from lower vertebrates[4,5]. Not until 1965, however, was there any report of the toxic effects of schistosomes on mammalian cells in culture[6]. It is now suggested that abnormal changes occur in monkey heart cell cultures to which viable eggs or egg extracts of *Schistosoma mansoni* have been added. Some of the effects include: breakdown of the monolayer growth pattern, loss of selective permeability against eosin Y, and metabolic inhibition (that is, no drop in *p*H) of treated cultures.

Compared with the eggs of *S. mansoni*, invading cercariae produce minor effects on host cells *in vivo*. The potential toxicity of cercariae, however, is interesting because they, like the egg stage, seem to depolymerize non-cellular tissue barriers but with little effect on mammalian cells[7,8].

Cercariae of *S. mansoni* were obtained when they emerged from infected *Australorbis glabratus*. The larvae were filtered through a 100 mesh stainless steel screen, refrigerated, and allowed to settle overnight in Imhoff cones. The sediment was washed by cold centrifugation in three changes of 0·9 per cent NaCl and stored at −30° C for up to 2 weeks.

Cercarial extracts were prepared by grinding the frozen larvae in sterile sand and adding enough cold, sterile, Earle's balanced salt solution to permit pouring of the material after standing for 4 h at 4° C. The Earle's solution contained 100 U of penicillin and 50 μg of streptomycin/ml. Solid debris was removed by cold centrifugation (1,200*g*) for 20 min, and the supernatant fluid was dialysed overnight at 4° C against 100 volumes of Earle's solution.

HeLa cells were cultivated on coverslips in Leighton tubes with bicarbonate-buffered medium 199 and 10 per cent calf serum. Antibiotics were included as described for Earle's solution. Warm, dialysed cercarial extract or Earle's solution, *p*H 7·4, was added to cultures previously rinsed with three changes of sterile balanced salt solution. A portion of the extract was heated in a water bath at 60° C for 1 h to test for thermolability. Gravimetric or colorimetric protein determinations were made from aliquots precipitated with two volumes of 20 per cent trichloroacetic acid[9,10]. Most extracts contained approximately 0·5 mg of precipitable protein/ml. Cultures were incubated at 37° C, examined every 30 min during the first 8 h, and again after 18–24 h. Parallel examinations were made of live as well as methanol-fixed cells stained with Giemsa.

The appearance of cells in a typical control culture held in Earle's solution is shown in Fig. 1; these cells retained their normal contours, had pale basophilic cytoplasm, and possessed open faced or vesicular nuclei. Their appearance was identical to that of cells treated with previously heated cercarial extract.

HeLa cells in cultures containing unheated extracts became refractile in 3–5 h and at the same time the cytoplasm became more basophilic than usual and there was a further intensification of basophilic staining as cells displayed cytoplasmic shrinkage.

Changes in the staining reaction suggested an initial concentration of basophilic components accompanying leakage and cytoplasmic retraction. This interpretation was supported by two observations: (*a*) that HeLa cells lost all but a few adhering shreds of cytoplasm as shown in Fig. 2, and (*b*) the packed cell volume of equal numbers of treated and control cultures was compared after pooling and centrifugation; the treated cells lost about 95 per cent of the packed volumes observed for control cultures. After cytoplasmic retraction, cells detached from the glass and the monolayer eventually disintegrated. After 18–24 h only free-floating, deeply basophilic, shrunken nuclei remained.

The suppressive effect of the antibiotics was checked by a visual search for bacteria in or on Giemsa- or Gram-stained cells, and by overnight incubation of the culture fluids in thioglycollate medium. The fluids remained bacteriologically "sterile" and it was concluded that only unheated cercarial extracts had caused the cellular damage during the previous period of observation.

Unsuccessful attempts were made to introduce live cercariae into HeLa cultures: before transferring recently emerged live larvae into cultures, it was necessary to deplete and replace the original water with fluid isotonic

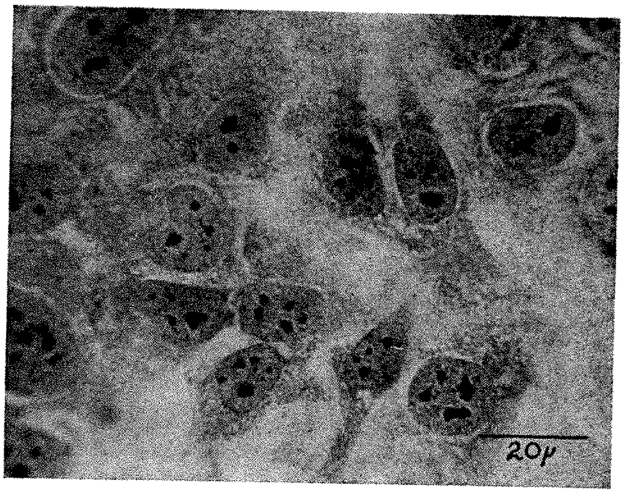

Fig. 1. HeLa cells after incubation in Earle's solution for 18 h at 37° C. (Giemsa stain.)

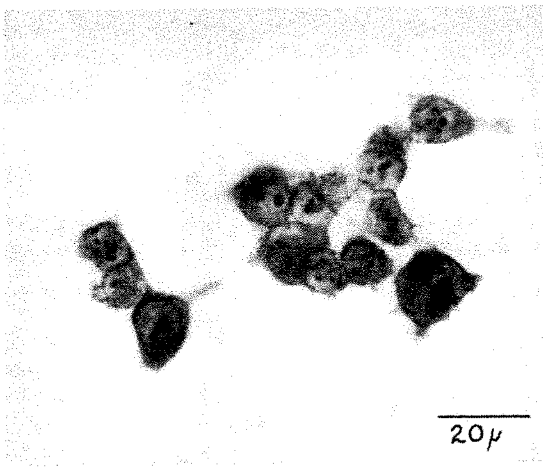

Fig. 2. HeLa cells after 7 h incubation with cercarial extract. The normal contour of the cells was obliterated leaving basophilic nuclei with narrow margins of basophilic cytoplasm.

to mammalian cells. The larvae were concentrated to a small volume on a sterile fritted glass filter, dialysed against sterile Earle's solution for several hours at room temperature, and inoculated into monolayer cultures. Practically all the larvae were dead after 18 h at 37° C, and the HeLa cells seemed to be normal.

If Medium 199 containing 10 per cent serum was used as the solvent for cercarial extracts, no cytopathogenic changes occurred. This was observed after testing 10 per cent calf, rat, mouse, or any of several different species of monkey sera. The results agree to some extent with the fact that normal animal sera also contain substances inhibitory to some cercarial enzymes[11].

In evaluating the cytotoxic potential of *S. mansoni*, or any schistosome, the approach of Gutekunst, Browne and Meyers[6] should be favoured. These workers showed that the intact, viable eggs of the parasite were toxic for mammalian cells *in vitro*, suggesting that cells succumbed to exotoxic products from miracidia. I was unable to keep cercariae alive in HeLa cultures, and so it is possible that the lysosomal or other abnormally released materials contributed to the apparent toxicity of disrupted cercariae.

The alterations produced by cercarial extracts were in the nature of an "all or none" response in the absence of serum. It seems, however, that viable eggs of *S. mansoni* can exert their effects despite the presence of serum in conditions necessary for normal growth of mammalian cells. It is concluded that experimental cell damage requiring disrupted cercariae and the exclusion of serum suggests a low cytotoxic potential for this stage of *S. mansoni*.

Homologous Alkaline Phosphatases and Homologous Loci in Two Sibling Species of European Anopheline Mosquitoes

Anopheles atroparvus and *Anopheles labranchiae* are two sibling species belonging to the maculipennis group of European anopheline mosquitoes. They may be considered the most closely related species of the group; their gene pools are probably the most similar. By the definition of Lorković they could be termed "semispecies", showing some of the characteristics of the species and some of subspecies[1]. Individuals of *A. atroparvus* and *A. labranchiae* are not clearly distinguishable by cytogenetic analysis of the banding pattern of the salivary chromosomes. They can be distinguished on the basis of slight differences in the micromorphology of the eggs, and also on the basis of hybridization data: the interspecific hybrid males are sterile, but introgressive hybridization is possible, for the females can be backcrossed to *A. atroparvus* and *A. labranchiae* males, and again produce normal females and several normal males.

Individuals of *A. atroparvus* and *A. labranchiae* can easily be distinguished at the fourth larval stage by comparing the relative electrophoretic mobility of two specific non-polymorphic bands showing alkaline phosphatase activity, arbitrarily designated Aphl (ref. 2).

If amino-acid sequences in proteins are colinear with the nucleotide sequences of the DNA subunits which code for them, and if the different relative electrophoretic mobilities of homologous proteins are an expression of their different molecular structure, it can be concluded generically that there is no identity between the structural gene or genes controlling the synthesis of the proteins examined in both species. Such conclusions raise the following questions. (*a*) Are these catalytically homologous proteins also homologous molecules? (*b*) Are they phenotypic expressions of the activity of a single genetic locus in both species? (*c*) If the answer to question (*b*) is affirmative, are then the specific loci under examination also homologous?

To answer these questions, I used the following experimental results. (1) Hybrids at the fourth larval stage obtained from the crosses: *atroparvus* males × *labranchiae* females (pair matings) and *labranchiae* males × *atroparvus* females (forced copulation) have given Aphl bands which always show intermediate electrophoretic mobility compared with Aphl of the parental species. (2) The same type of intermediate band has also been obtained *in vitro*, by mixing *atroparvus* and *labranchiae* homogenates, freezing them in the presence of 1 molar NaCl and then thawing, and applying them to a gel for electrophoresis (Fig. 1). (3) The same results were also obtained when *A. atroparvus* and *A. labranchiae* were simply ground together and the homogenates maintained at room temperature for a few minutes before electrophoresis.

It was not possible to obtain typical electrophoretic patterns showing three distinct bands, which heterozygous variant forms of dimeric proteins usually produce[3]. In this case, the indication is that the phenomenon occurs when two alleles producing different polypeptide subunits are brought together in a hybrid.

In spite of this gap, I think that these results could still be interpreted as representing the phenomenon already mentioned. The differences in relative mobility between Aphl of *A. atroparvus* and *A. labranchiae* were very small, and the hybrid pattern constantly appeared as a zone of intermediate mobility, in which the bands were also thicker and less well defined than those of Aphl of the parental species. It could therefore be possible to conclude, according to Coates[4], that this pattern is caused by the recombination of polypeptide chains, where two different bands, and another with intermediate mobility, are overlapping. Alternatively, the intermediate band of the hybrid larvae could represent

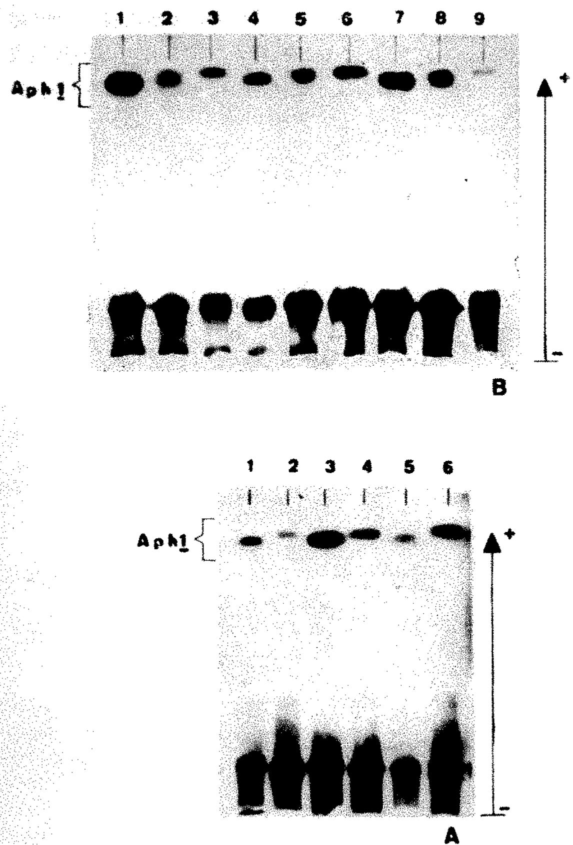

Fig. 1. Zymograms of single larva homogenates illustrating the electrophoretic relative mobility of Aph1. *A*, 1, 3, 5, *atroparvus*; 2, 4, 6, *labranchiae*. *B*, 1, 4, 7, *atroparvus*; 3, 6, 9, *labranchiae*; 2, hybrid (*atroparvus* male × *labranchiae* female); 8 hybrid (*labranchiae* male × *atroparvus* female); 5, hybrid band obtained *in vitro*. Methods for starch gel electrophoresis and staining for phosphatase were described earlier[2].

principally a hybrid enzyme molecular form. In other words, the fact that the hybrid larval pattern has appeared as a thicker band of intermediate mobility could be considered significant in suggesting that the hypothesis stating that no molecular hybridization takes place between *A. atroparvus* and *A. labranchiae* Aph1 subunits is invalid.

On the other hand, the following genetic data fit this consideration. (*a*) Individuals at the fourth larval stage, obtained from the backcross *A. atroparvus* males × hybrid females (introgressive hybridization by pair matings), have given the typical band of *A. atroparvus* and the typical band of the hybrids, according to the Mendelian ratio 1 : 1. (*b*) Individuals at the fourth larval stage, obtained from the backcross *A. labranchiae* males × hybrid females (introgressive hybridization by forced copulation), have also given alternatively the band typical of *A. labranchiae* and the band typical of the hybrids, according to the Mendelian ratio 1 : 1 (Table 1).

These results suggest that both the larval alkaline phosphatases of *A. atroparvus* and *A. labranchiae* are controlled by autosomal genes, specifying the primary molecular structure of the polypeptide subunits which form the catalytically active proteins. On the basis of these data the hypothesis that the enzymes Aph1 of the two sibling species are homologous molecules with two associating subunits, which are identical at the intraspecific level and non-identical, but homologous at the interspecific level, seems to be consistent. In other words, the sibling species *A. atroparvus* and *A. labranchiae* should possess electrophoretically pure enzymes, not identical but homologous, each possessing two identical subunits, while their hybrid offspring should possess hybrid enzymes with two different subunits.

Table 1

	Total No. of examined individuals	*Slow Aph*1 deduced genotype $Aph1^s/Aph1^s$	*Intermediate Aph*1 deduced genotype $Aph1^s/Aph1^f$	*Fast Aph*1 deduced genotype $Aph1^f/Aph1^f$
A. atroparvus	250	250	0	0
A. labranchiae	250	0	0	250
Hybrids (*at.* ♂ × *lab.* ♀)	50	0	50	0
Hybrids (*lab.* ♂ × *at.* ♀)	50	0	50	0
Backcross (*at.* ♂ × hybrid ♀)	60	28	32	0
Backcross (*lab.* ♂ × hybrid ♀)	81	0	37	44

I would like to point out, however, that this biochemical interpretation can be considered reasonably correct, but not sufficiently proved.

On the contrary, it is well established that the differences in electrophoretic pattern of the two species are phenotypic expressions of the activity of a single locus. Although these genetic data do not contradict the hypothesis that the two genes coding for *Aph*1 do not occupy the same position in the genotype of the two species, it seems more correct and more feasible to assume that the genes in question are homologous. In this hypothesis, the structural genes carrying the genetic information for *Aph*1 in *A. atroparvus* and *A. labranchiae* are viewed as alleles. One allele, which according to Beckman and Johnson[5] can be written $Aph1^f$, controls the synthesis of the fast moving enzyme of *A. labranchiae*, while the other allele ($Aph1^s$) specifies the structure of the slow moving enzyme of *A. atroparvus*.

It has been impossible to find electrophoretic variants either in *A. atroparvus* or in *A. labranchiae*, and the offspring obtained by backcrossing the hybrid females to the males of the parental species have segregated according to the ratio 1 : 1, and so I think that the *Aph*1 loci of both species can be considered to be homozygous and therefore monomorphic loci. Thus the *Aph*1 locus of *A. atroparvus* may be written $Aph1^s/Aph1^s$, that of *A. labranchiae* $Aph1^f/Aph1^f$, and finally that of the hybrids $Aph1^s/Aph1^f$ (Table 1).

Introduction of Yellow Rust Resistance of *Aegilops comosa* into Wheat by Genetically Induced Homoeologous Recombination

YELLOW rust (*Puccinia striiformis*) is a hazard to the cultivation of wheat (*Triticum aestivum* $2n = 6x = 42$) in many temperate regions. The most economic method of limiting losses of yield caused by the disease lies in the cultivation of varieties with genetically determined resistance to infection. Most current varieties owe their resistance to the activities of a few major genes which they carry in various combinations. New sources of resistance, however, must be sought continually because mutation or somatic recombination in the pathogen can give rise to genetic variants against which particular resistance genes or combination of genes, in current use, cease to be effective.

In the search for new forms of disease resistance for use in wheat improvement, attention has often been turned to related species, some of which display outstanding levels of resistance. For example, the wild annual grass

Aegilops comosa ($2n = 14$), which is distributed around the Aegean Sea in Greece, Turkey and Crete, has especially good resistance to yellow rust[1]. Like all species in the genus *Aegilops*, *Ae. comosa* is closely related to wheat in an evolutionary sense and *T. aestivum–Ae. comosa* hybrids can be produced by hand pollination and hybrid–embryo culture. In our work we have incorporated the yellow rust resistance of *Ae. comosa* in wheat by interference with the genetic regulation of meiotic recombination. Such procedures have never previously been used in crop improvement.

Riley, Chapman and Macer[2] initiated a backcrossing programme from 28-chromosome hybrids derived from the cross *T. aestivum* 'Chinese Spring' × *Ae. comosa*, using 'Chinese Spring' as the recurrent parent. After the second backcross, selection was practised for resistance to yellow rust. The result of this programme was the isolation of a 44-chromosome addition line that had the forty-two chromosomes of 'Chinese Spring' and the pair of chromosomes of *Ae. comosa* determining rust resistance. It was further shown that this pair of *Aegilops* chromosomes would substitute for chromosomes $2A$, $2B$ and $2D$ of the wheat complement, but for no other chromosome. The *Aegilops* chromosome, determining rust resistance, is therefore closely related genetically to the chromosomes of wheat homoeologous group 2. Indeed, it can be regarded as homoeologous with these chromosomes, and designated $2M$ because *Ae. comosa* carries the *M* genome.

In normal circumstances, however, chromosome $2M$ does not pair and recombine with any wheat chromosome[2]. Consequently, the single gene on chromosome $2M$, which is presumed to be responsible for rust resistance, cannot be incorporated in a wheat chromosome without further manipulation. Nevertheless, it seemed likely that chromosome $2M$ would recombine, at meiosis, with its wheat homoeologues if the genetic suppression of homoeologous recombination normally exercised by chromosome $5B$ were removed[3,4].

To achieve this condition, use was made of another *Aegilops* species, *Ae. speltoides* ($2n = 14$), which has the property of inhibiting the $5B$ activity in wheat hybrids[5–7]. Thus in *T. aestivum* × *Ae. speltoides* hybrids there is homoeologous chromosome pairing and recombination. In the present work, therefore, the line with chromosome $2M$ added to the normal complement of 'Chinese Spring' was crossed with *Ae. speltoides*. The resulting 29-chromosome hybrids had twenty-one chromosomes of *T. aestivum*, seven chromosomes of *Ae. speltoides* and chromosome $2M$ of *Ae. comosa*. Because of the inhibition of the $5B$ activity, recombination could take place at meiosis in these hybrids between chromosome $2M$ and its homoeologues in the wheat complement.

A backcrossing programme was initiated from these 29-chromosome hybrids using *T. aestivum* 'Chinese Spring' as the recurrent parent. After the first backcross, selection was practised for rust resistance. In the third backcross generation a 42-chromosome, rust-resistant plant was isolated that formed twenty-one bivalents at meiosis. This plant was heterozygous for a dominant rust resistance condition and homozygotes were isolated in its progeny.

A line homozygous for rust resistance was thus established which, when crossed with standard wheat varieties, gives hybrids that form twenty-one bivalents at meiosis. In the F_2 generation, derived from hybrids between 'Chinese Spring' and this rust resistant line, segregation fits the ratio three resistant : one susceptible, so that the resistance introduced from *Ae. comosa* is inherited as though determined by the dominant allele at a single locus; designated Yr_8. The resistant line has been called 'Compair' to indicate that it has a pair of genes for yellow rust resistance derived from *Ae. comosa*.

The study of meiotic pairing configurations in cytologically marked hybrids, and of the disturbance of segregation ratios in the F_2 generations derived from monosomic hybrids, shows that, in the origin of 'Compair', homoeologous recombination took place in the long arm of chromosome $2M$ and the right arm of chromosome $2D$. The recombined chromosome, that is homozygous in 'Compair', has a distal segment of the right arm of $2D$ and a proximal segment of the long arm of $2M$; while the centromere and the entire short arm are derived from $2M$. This is the first example of the introduction of useful alien genetic variation into wheat by genetic interference with the regulation of recombination in the manner originally proposed by Riley and Chapman[3].

The *Ae. comosa* form of yellow rust resistance, carried by 'Compair', is effective against races $2B$, 3/55 (Opal-attacking), $8B$, 54 and 60; giving 00-0 reactions in every case. Indeed, this form of resistance is effective against all variants of the pathogen to which it has so far been exposed.

'Chinese Spring' was the recurrent wheat parent in the breeding programme because its use simplifies cytogenetic procedures and allows a rapid turnover of generations. Of course, the incorporation of the alien yellow rust resistance in a genotype which is close to that of 'Chinese Spring' means that further work must be carried out to establish it in an agriculturally acceptable genotype. This presents no further cytogenetic problems, however, for the recombined $2M$–$2D$ chromosome pairs at meiosis in intervarietal heterozygotes with chromosome $2D$ and segregates normally, apparently with unimpaired transmission through both pollen and eggs. Consequently, 'Compair' can be treated as a normal wheat variety in planning breeding programmes and breeders need have no particular concern for chromosome behaviour in the derivatives of hybrids of which it was a parent.

In phenotype 'Compair' is close to 'Chinese Spring' but with longer spikelets, florets, glumes and grains. These are attributes that may result from the activities of *Ae. comosa* genes linked to Yr_8—the rust resistance gene. In 'Compair' the development of awns is very variable because on the same plant some spikes may have short scurs while others are fully awned.

Seeds of 'Compair' will be supplied to all breeders and pathologists who would like to use them.

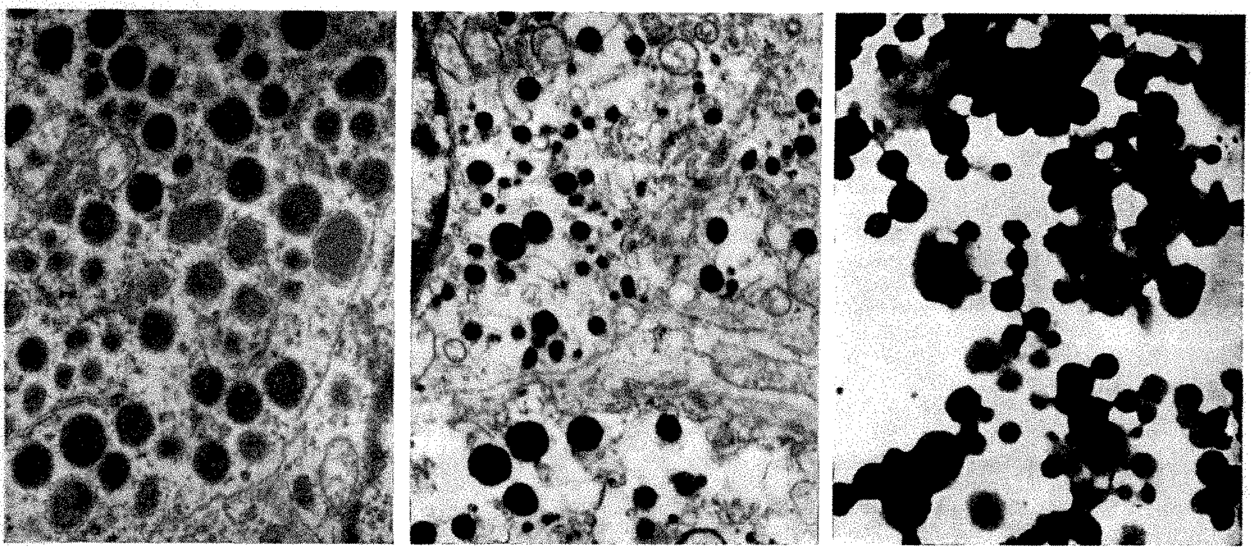
Determining Sizes and Distribution of Sizes of Spherical Bodies such as Chromaffin Granules in Tissue Sections

QUANTITATIVE microscopy is difficult at the ultrastructural level because many organelles and inclusions have irregular shapes and the images represent chance sections through bodies of unknown orientation. Size determination for chromaffin granules is easier than for many other inclusions or organelles because their profiles are usually rounded in section and in isolated granule preparations (Fig. 1) implying a spherical form and so orientation presents no problem.



A *B* *C*

Fig. 1. Electron micrographs of bovine *A*-cell granules (*A*), *N*-cell granules (*B*) and isolated granules (*C*). Fixed initially in buffered glutaraldehyde (× 12,000).

After fixation with the glutaraldehyde/osmium tetroxide sequence and staining[1] the membrane-bound adrenaline-storage (*A*) and noradrenaline-storage (*N*) granules can be identified by their moderate or high electron-density.

Uncorrected measurements of granule profiles are not a true picture of the distribution of sizes of chromaffin granules within the tissues, for they ignore factors such as planes of sections, relative size of granules and section thickness. I have now applied methods which correct for these factors to test systems and electron micrographs. The correction is carried out in two stages.

(1) *The conversion of profile numbers to granule numbers.* This correction makes use of the fact that when size-distribution curves are plotted for cellular inclusions these are grouped into a series of size ranges.

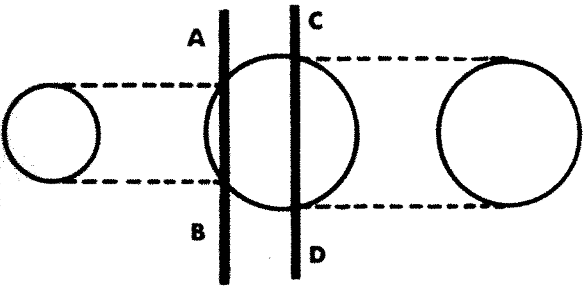


Fig. 2. Variations in profile diameter with plane of section (*A–B* and *C–D*) through a spherical body (centre).

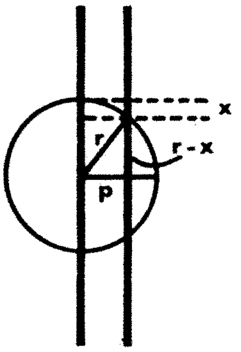

Fig. 3. Circle represents a spherical body and the two vertical lines planes of sections. The proportion (y) of the body falling within profile diameters $2r$ to $2r-2x$ may be calculated for different values of r and x. $y = p/r \times 100$ per cent.

Most single membrane-bound chromaffin granules are spherical, and so sections through them appear as circular profiles, with diameter increasing towards the centre of the granule (Fig. 2). Profiles can be grouped into size ranges 0 to x, x to $2x$, $2x$ to $3x$ units, etc.

With a granule $2r$ units in diameter (r = radius) profile diameters between $2r$ and $2r-x$ can conveniently be counted. Next smallest groups are, in order, $2r-x$ to $2r-2x$, etc. The interval x can be selected for a particular problem and magnification. For a plane of section giving a profile diameter of less than $2r$ the proportion of the granule available (y) for section within a particular range may be calculated (Fig. 3),

$$\text{that is, } y = \frac{p}{r} \times 100 \text{ per cent}$$

while in this case $p = r\cos\theta$ or $p = \sqrt{(2xr - x^2)}$.

If sufficient profiles can be measured, y per cent of all cuts will fall within the range $2r$ to $2r-x$ and $100-y$ per cent will fall within the lower ranges. Thus the number n of granules which fall within the range $2r$ to $2r-x$ corresponds to y per cent of all granules sectioned and the total number of granules present

$$n_t = n \times \frac{100}{y}$$

Relative numbers of circles adjusted to 13 mm = 100	262		152			123							100
True relative proportions	265		159			112							100

If granules are initially in a series of specific sizes equal to the maximum for each range (this becomes more correct as size range is reduced), and if the largest granules are considered first, the previous statements can be applied to a mixed population of granules. Given an adequate granule profile count the number (n_1) of granule profiles of the largest size range ($2r_1$ to $2r_1-x$) represents y_1 per cent of all granules (size $2r_1$) present in the section(s) and the total number (n_{1t}) of these is

$$n_{1t} = \frac{n_1 \times 100}{y_1}$$

n_{1t} exceeds n_1 and the difference $n_{1t}-n_1$ represents granules of this size which have been sectioned further from the centre; these will have been counted within the ranges $2r_1-x$ to $2r_1-2x$, $2r_1-2x$ to $2r_1-3x$, etc. The number in each of these ranges can be calculated, that is y_1 per cent of granules, within the range $2r_1$ to $2r_1-x$, y_2 per cent of granules within the range $2r_1$ to r_1-2x, y_3 per cent within $2r_1$ to $2r-3x$. Hence y_2-y_1 per cent of granules must lie within the range $2r_1-x$ to $2r_1-2x$ and y_3-y_2 per cent of granules lie within the range $2r_1-2x$ to $2r_1-3x$ and so on.

Once all granules of size $2r_1$ to $2r_1-x$ have been accounted for and the number present in each other size range deducted from the initial counts, that is the number n_2 in the second largest column becomes

$$n_2 - \left(n_{1t} \times \frac{y_2-y_1}{100}\right)$$

the same method can be applied to the next largest group until all have been corrected.

This correction ideally requires an infinitely thin section, but permissible thickness varies with size ranges selected, size of granules and minimum thickness of granule (considered to be 100 Å) which allows identification. In this work, using the parameters indicated later for electron micrographs, errors arising from thickness are significant only in the four smaller size ranges and no extra correction has been introduced for this factor or for the tangential slope of the margin of sections through the edge of granules. Table 1 shows variations in y with r and x; this can be extended to cover other profile diameters and ranges.

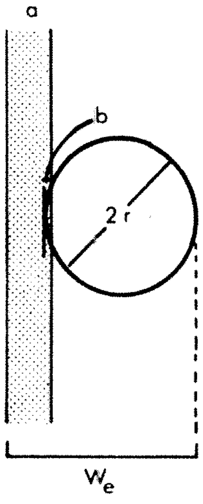

Fig. 4. Circle represents a spherical body. The effective thickness of the body in tissue, $W_e = 2r + a - b$, where a is the thickness of the section and b is the depth of the body which must be sectioned in order to allow recognition in optical system.

(2) *The correction for granule size and section thickness.* In a block of tissue containing randomly distributed granules of different sizes, the likelihood of an infinitely thin section passing through a particular size of granule will depend on the relative sizes of the granules and the number of granules of each size. The latter has been dealt with in correction 1. In considering the relative sizes of granules, section thickness (a) must also be taken into account because the effective width (W_e) of a particular granule is increased by the section thickness (Fig. 4) and becomes $W_e = 2r + a - b$ where b is the minimum thickness of granule allowing identification. The chance of a section passing through a particular granule is proportional to the effective width of the section, and in any section the total number of granules of each size range should be corrected for this factor, namely n_{1t} requires no correction, n_{2t} becomes

$$n_{2t} \times \frac{W_{e_1}}{We_2}, \; n_{3t} \text{ becomes } n_{3t} \times \frac{W_{e_1}}{W_{e_3}}$$

(n_{1t} = number of largest granules after correction 1, n_{2t} next largest column and so on).

Using a model system containing 864 randomly distributed circles 1, 3, 6 and 13 mm in diameter on which randomly directed and positioned lines are superimposed, arcs may be measured (Table 2) to assess the method for profile-to-granule number conversion (correction 1). Numbers of circles of various sizes intersected by lines or bands (representing different section thicknesses) were also determined (Table 3) to assess correction 2, using the formula $2r + a - b$ where $b = 0$.

Table 3. MODEL SYSTEMS

Scan	Circle diameters (mm) 1	3	6	13
Single line—uncorrected	82	142	220	384
Single line—corrected for size of circles	1,050	615	475	384

8 mm bandscan	101	73	63	86
8 mm bandscan—corrected for size and band width	236	140	95	86
8 mm bandscan—corrected and adjusted to 13 mm = 100	275	162	110	100
16 mm bandscan	186	125	106	120
16 mm bandscan—corrected for size and band width	316	191	140	120
16 mm bandscan—corrected and adjusted to 13 mm = 100	264	158	116	100
True relative proportions	265	159	112	100

Correction for size of circles (representing inclusions) and intersecting line/band width which represents different thicknesses of sections.

The results (Tables 2 and 3) agree well with true proportions. The small negative and positive counts for certain size ranges following correction 1 may result from inaccurate measurement (difficult with tangential sections) or from a population sample which is too small.

This method has been illustrated with electron micrographs. Initial magnifications were × 6–10,000; final print magnification × 24,000 so that 1 mm = 420 Å. Granule profile diameters were measured within the ranges 0–1, 1–2, 2–3 mm, etc. Diameters of the electron-dense contents were measured, for the membranes may be distorted.

Table 4 records profile diameters and initial correction for extra-adrenal (N) granules of a 9 day old rabbit. Granules in column F have a maximum diameter of 6 mm; hence $r_F = 3$. Range of column F is therefore r_F to r_F-

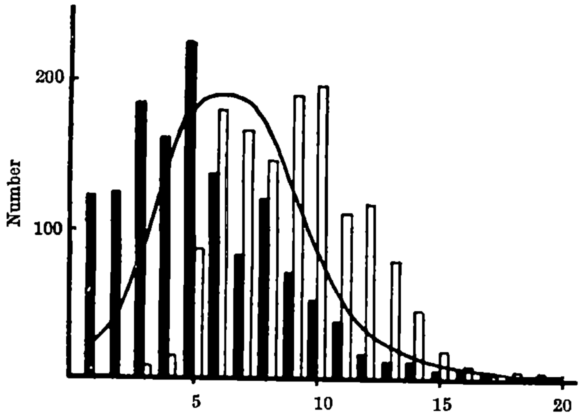

Fig 5 Histogram showing distribution of sizes of *A* and *N* granules of bovine adrenal slices with superimposed curve showing distribution of sizes of granules in an isolated granule preparation ■, *N* granules, □, *A* granules Scale, 1 mm = 420 Å

0 5 From Table 1, 55 per cent of profiles of granules size $r_F = 3$ would fall within this range, so that the total number (n_{Ft}) of granules ($r_F = 3$) in the sample,

$$n_{Ft} = \frac{4 \times 100}{55} = 7 \text{ (to the nearest whole number)}$$

Three of these will be present as smaller profiles in other columns From Table 1, 74 per cent of the profiles of these granules will be found for the range r_F to $r_F - 1$, that is in columns *E* and *F*, thus column *E* contains 19 per cent of these granules, that is

$$\frac{7 \times 19}{100} = 1 \text{ (to the nearest whole number)}$$

For the range r_F to $r_F - 1\ 5$ (columns $D+E+F$) 86 per cent of the granule profiles are found so that the number in

$$D = \frac{7 \times 12}{100} = 1$$

For the range r_F to $r_F - 2$ (columns $C + D + E + F$) 97 per cent of the granule profiles will be found, hence *C* contains

$$\frac{7 \times 11}{100} = 1$$

These counts relating to the 5–6 mm granules are now subtracted from (Table 5) the original counts of columns *C*, *D* and *E*

The same correction is then applied to the next largest group, that is those in column *E* The maximum radius of these profiles is 2 5 mm and column *E* corresponds to the range r_E to $r_E - 0\ 5$ From Table 1, 61 per cent of granules radius = 2 5 mm fall within this range, hence the total present in the section is

$$\frac{31 \times 100}{61} = 51$$

For the range r_E to $r_E - 1$ (columns $E+D$) 80 per cent of the profiles will occur, thus 19 per cent of these will appear in column *D*, that is

$$\frac{51 \times 19}{100} = 10$$

Thus the number of profiles listed under *D* must be further adjusted to 184 − 10 = 174 and so on throughout the series The corrected counts are indicated in Table 4

Table 4 NUMBER OF GRANULE PROFILES AND CHROMAFFIN GRANULES IN TISSUE SECTIONS, AND DISTRIBUTION OF SIZES OF CHROMAFFIN GRANULES IN A 9 DAY OLD RABBIT

Column	*A*	*B*	*C*	*D*	*E*	*F*	*G*	*H*	*I*	*J*
Size range (mm)	0–1	1–2	2–3	3–4	4–5	5–6	6–7	7–8	8–9	9–10
Extra-adrenal *N* cells										
No of profiles in section(s)	108	293	373	185	32	4				
No of granules in section(s)	40	220	412	264	51	7				
Size distribution of granules	156	520	742	372	59	7				
Adrenal *A* cells										
No. of profiles in section(s)	0	53	123	177	136	58	46	13	2	0
No of granules in section(s)	< 0	< 0	128	186	182	73	79	23	4	0
Size distribution of granules			335	384	309	106	100	26	4	0

Scale, 1 mm = 420 Å

With highly electron dense *N* granules no negative counts are obtained (Tables 4 and 6) With the less electron dense *A* granules of adrenal medulla, however, some negative figures are obtained for lower size ranges Population samples of similar sizes (> 800) were used for both *A*- and *N*-granule counts, and so this phenomenon is unlikely to be a result of sampling It may, however, result from the difficulty and near impossibility of satisfactorily identifying tangential sections through the less dense (*A*) granules or from a virtual absence of small *A* granules possibly because of a different method of synthesis or rate of turnover of *N* granules With *N* granules, correction 1 serves as a check on the accuracy of measurement and adequacy of population sample

Table 5 PARTIALLY CORRECTED PROFILE AND GRANULE COUNTS OF EXTRA-ADRENAL CHROMAFFIN CELLS OF 9 DAY OLD RABBIT

Column	*A*	*B*	*C*	*D*	*E*	*F*
Size range (mm)	0–1	1–2	2–3	3–4	4–5	5–6
No of profiles in section(s)	108	293	373–1 = 372	185–1 = 184	32–1 = 31	3
No of granules in sections						7

Scale, 1 mm = 420 Å

After the profile-to-granule-number correction, correction 2 is applied Effective thickness = $2r + a - b$, $a = 400$ Å, $b = 100$ Å, hence

$$\text{for column } E = 51 \times \frac{2r_F + 300}{2r_E + 300} = 51 \times \frac{2{,}520 + 300}{2{,}100 + 300}$$

$$\text{for}' \text{column } D = 264 \times \frac{2r_F + 300}{2r_D + 300} = 264 \times \frac{2{,}520 + 300}{1{,}680 + 300}$$

Scale, 1 mm = 420 Å

There is a general shift to the right of the counts after correction 1 because many small profiles are sections through peripheral zones of large granules After correction 2 there is a marked increase in the relative numbers of the smaller granules

Only sections showing a mixed population randomly scattered were included in this analysis, avoiding regions such as the Golgi zone, where a variation in size of granules is common[2]

Table 6 shows the results of applying the same corrections to bovine *A* and *N* cells and also indicates that the size distribution of isolated granules is similar to those in sections of adrenal medulla allowing for the relative proportions of the two amines in the bovine adrenal medulla (*A* . *N* = 75 · 25) (ref 3) The histogram (Fig 5) clearly illustrates that bovine *A* granules have a larger mean diameter than *N* granules

These methods are applicable at both the ultra-structural level and in light microscopy if an appropriate section thickness relative to object size and size ranges are selected, that is using the light microscope for nuclear size 0 5 – 1μ sections would be used

GENERAL

Neutron Activation Analysis of Medieval Ceramics

An increasing awareness of the number of British medieval pottery kilns working at any one time has thrown into sharp perspective the problem of establishing local ceramic sequences by programmes of kiln excavation Traditional methods and residual magnetic dating techniques often enable reasonably precise dates to be given to kilns and thus their products It remains, then, to establish a technique whereby material excavated from sites other than kilns can be identified back to its source of production, and thus to make use of scientifically established dates Recently neutron activation analysis has been used with some success to distinguish between specimens of ancient pottery[1–5] and glass[6]. Differences in concentrations of trace elements in samples have been noted A programme of work has therefore been initiated, using lithium-drifted germanium detectors, to examine the trace element constituents of pots from some eighty British kiln sites

Preliminary experiments have been carried out on shards from Olney Hyde, Buckinghamshire, and Holme-on-Spalding-Moor, Yorkshire Fragments of approximately 50 mg of materials were irradiated in a thermal neutron flux of 10^{12} n cm^{-2} sec^{-1} in the BEPO reactor, AERE, Harwell, for 100 h Gamma ray spectra were then recorded at intervals during 6 weeks using a lithium–germanium gamma ray detector of sensitive volume approximately 7 c c , which was coupled through appropriate amplifiers to a 1024 channel pulse-height analyser A typical spectrum is shown in Fig 1 Peak intensities were ascertained from the digital output of the analyser and corrected for background by averaging counts in channels on either side of individual peaks The following active isotopes were identified in each sample sodium-24, scandium-46, iron-59, cobalt-60, caesium-134, lanthanum-140, cerium-141, europium-152, samarium-153, ytterbium-169, thulium(?)-170, ytterbium-175, lutetium-177, hafnium-181 Not all of these, however, were amenable to quantitative analysis In this preliminary experiment, all activities in a given sample were compared with that of the scandium 890 keV peak, when extrapolated to a fixed time after irradiation Ratios thus obtained give an arbitrary indication of the trace concentrations, relative to scandium, in a particular specimen These ratios for nine isotopes are given in Table 1 Very significant differences are apparent in the cases of lanthanum-140, europium-152 and samarium-153, the large differences in sodium-24 may be fortuitous in that no prominent photopeak of sodium was examined

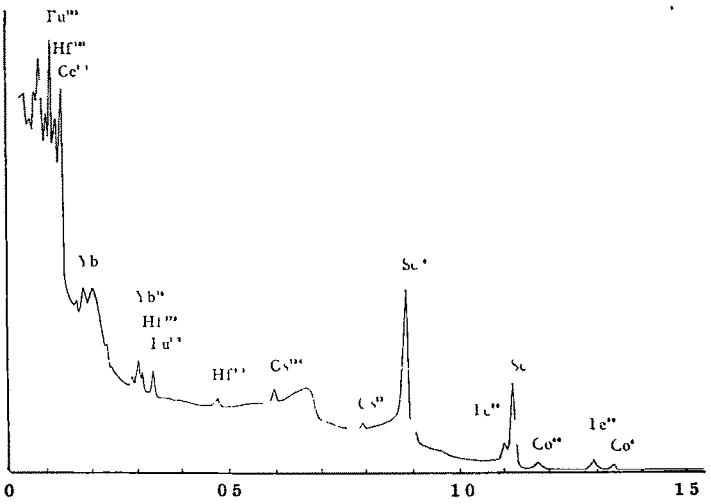

Fig 1 A gamma ray spectrum for a shard from Holme on-Spalding-Moor, Yorkshire, 100 h after irradiation

This investigation of shards from two kilns allows us to assume with fair certainty that fragments from one of the pots may be differentiated from those of the other, and a full programme of examination of kiln product groups has now commenced

BOOK REVIEWS

ASTRONOMY IN A NUTSHELL

Astronomy Old and New

By Ernest Agar Beet Pp x+189+16 plates (London G Bell and Sons, Ltd , 1967) 25*s* net

ASTRONOMY is probably the only major science in which the number of books for the tiro, the dedicated amateur and the layman with a passing interest exceeds the number written for the professional The general standard is correspondingly good, and the difficulty of saying anything new is correspondingly great Mr Beet's new book, continuing a personal tradition begun by his *The Sky and its Mysteries* (1952), is nothing if not up to date This applies to the plates, which include among several of the old favourites some of the Ranger 9 pictures

The book is not only new in the sense of cramming in last-minute information It is unusual in the attention given to the astronomer's equipment, which must now be taken to include satellites and space probes It is unusual in its good bibliographical supplements to individual chapters All told, it will be found useful for sixth form teaching, and for supplementing courses in astronomy in such institutions as our colleges of technology It is essentially a book requiring its own supplementation, however It is short, and yet the new has not so much squeezed out the old as compressed it, to the point of mild obscurity in places Thus the second chapter, nineteen pages long, is a rapid conspectus of four thousand years of astronomical history The relevance to the book of this chapter would have been suspect even had it not contained many small errors of fact (The most misleading is perhaps that relating to the period of Mars in its epicycle, on page 15 wrongly stated to be equal to the period in the deferent Babylonian and Egyptian astronomy are, moreover, sadly confused) The accuracy of the work is not so much in question as the need for such excessive brevity The last seven pages, for example, covering modern cosmology, are like a mirage to a man lost in a desert of understanding His temperament is what will determine whether he should give up in despair, or turn to more substantial works on the same subject On the whole, the second reaction seems the more probable, and this is ample justification for a work of this kind

CHANCE CHANGES LITTLE

The Doctrine of Chances

Or A Method of Calculating the Probabilities of Events in Play By A de Moivre Pp xxvi+257 (London Frank Cass and Co , Ltd , 1967 First published 1718) 105*s*

IT is perhaps not usual for this journal to review a reprint of the second edition of a work which has already proceeded to its third edition, but none of the three editions were reviewed here when they came out, for unavoidable reasons, and so some notice seems deserved De Moivre's famous work was first published in 1718 This is an exact reproduction of the second (1738) edition, with an index and table of contents added The third edition appeared in 1756, I do not know to what extent it differed from the second

Two hundred years have dated the book very little, and it makes most refreshing reading For historians of science its re-issue must be a great blessing, but statisticians even without an historical sense could not fail to find it of great interest This is because, whether de Moivre is writing about the "meaning" of a "chance", or about the interpretation of data, he is concerned with old questions still full of perplexity and still liable to arouse controversy The applications discussed in the book are, as might be expected, to gambling and to actuarial science Those who wish to compare this book with a review of the present state of those two applications may wish to refer to L E Dubins and L J Savage, *How to Gamble if You Must* (McGraw-Hill, 1965), and to K Borch's article "The Theory of Risk" and the accompanying discussion in the *Journal of the Royal Statistical Society*, Series B (29, 432, 1967) For modern developments of de Moivre's limit theorem a good reference would be the second edition of W Feller's *Introduction to Probability* (Volume 1, Wiley, 1957), and for the latest developments of the combinatorial approach to which de Moivre made great contributions a useful reference is L Takács, *Combinatorial Methods in the Theory of Stochastic Processes* (Wiley, 1967)

The general editor (Dr L L Laudan) and the publishers of the Cass Library of Science Classics are very much to be congratulated on making this important work once more generally available D G **KENDALL**

METAL STRUCTURE

Structure of Metals

Crystallographic Methods, Principles, and Data Third edition By Charles S Barrett and T B Massalski (McGraw-Hill Series in Materials Science and Engineering) Pp xvii+654 (London and New York McGraw-Hill Publishing Company, 1966) 126*s* , $15 75

THIS book presents a new edition of the original classic text first published by C S Barrett in 1943 and revised in 1952 Now under dual authorship the contents remain, nevertheless, in general, much as before without any noticeable change in philosophy or presentation

The first four chapters discuss the fundamentals of crystal lattices, crystal nomenclature and standard projections, together with the basic principles of the reciprocal lattice and diffraction of X-rays by crystals Then follows, in Chapters 5 to 9, a descriptive treatment of the various experimental X-ray methods, that is, Laue, rotating crystal, powder method, crystal structure determination and texture methods The other common experimental methods of studying the structure of metals and alloys are treated later in the book with X-ray and electron microscopy in the fifteenth chapter, stress measurement by X-rays in Chapter 17, ending with electron and neutron diffraction in Chapters 22 and 23 Between the two treatments of methods, the authors present the crystal, electronic and defect structure of metals and alloys including superlattices together with the relevant modern theories (Chapters 10 to 14) The remainder of the book is taken up in discussing some selected research results where X-ray methods seem to have been of value, such as Fourier analysis of particle size, strain or stacking fault broadening in Chapter 16, solid state phase transformations in Chapter 18 and preferred orientations after various treatments in Chapters 19, 20 and 21

The material and coverage of topics in this text remain as broad as in the previous editions with much revision, expansion and modernization This has been possible only at the expense of the more elementary sections, which the authors justify on the grounds that such elementary material is adequately covered in other books and is already familiar to most readers The book therefore presents a strange mixture of the elementary, intermediate and advanced, and as a consequence is unsuitable in treatment for all but a few undergraduate and graduate students There is too much emphasis on research for undergraduates to buy the book, which is too broad to be of real use to the graduate student and researcher Even the detailed treatments such as preferred orientation, and microscopy involving X-ray and electron diffraction, are of limited value because the researcher invariably consults the more detailed up to date work of, for example, the A S M book on *Recrystallization, Grain Growth and Textures* and *Electron Microscopy of Thin Crystals*, respectively Thus although such a book as *Structure of Metals* was invaluable up to the early sixties, its usefulness today is much more limited Nevertheless, a tremendous amount of work has been put into the present edition and no doubt the book will still be useful as a quick reference to a wide variety of topics, without being the classic of the earlier years

R E. SMALLMAN

FLAME PHOTOMETRY

Flame Photometry Theory

By E. Pungor Translation edited by R A Chalmers (The Van Nostrand Series in Analytical Chemistry) Pp x+200 (London D Van Nostrand Company, Ltd ; Princeton, N J. D Van Nostrand Company, Inc , 1967) 60*s*

THIS is a very worthwhile book, collecting together a wealth of scattered information on flame processes in the broadest sense of the term Flame photometry is now a widely used analytical tool, the ease and rapidity with which it produces data engender a temptation to relegate the underlying principles to a subsidiary role There are few areas in analytical chemistry where the relationship between theory and practice is as tenuous as it is in emission spectrography. The book is written primarily for analysts and it will certainly be welcomed by them. It serves to underline the fact that the apparently simple and rugged technique of flame photometry is based on complex interrelationships of chemical and thermal processes It can be recommended to a wider readership as an informative text

Considerably more than half of the book is devoted to two important chapters The first is a survey of flame processes, covering the basic parameters for evaluating flame performance together with the experimental techniques involved The various theories of flame propagation are also discussed The second chapter is concerned with radical equilibria in flames and again a substantial amount of experimental information is given The treatment is largely concerned with hydrogen/oxygen flames, but the literature on hydrocarbon flames is adequately covered The remainder of the book is made up of brief chapters on flame temperature and its measurement, important flames used in flame photometry, theory of atomization and spray collection (based largely on the author's own work) and flame emission and atomic absorption spectroscopy It is well produced and reasonably priced.

J. K FOREMAN

AUSTRALIAN LANDFORMS

Landform Studies from Australia and New Guinea

Edited by J. N Jennings and J A Mabbutt Pp xxiii+434 (London Cambridge University Press, 1967) 105*s* ; $19.50

THIS is a very Australian book It is a collection of essays dealing with landforms in Australia and New Guinea The three essays concerned with New Guinea are almost exclusively confined to the highlands The other fourteen essays cover many characteristic aspects of Australian landform study, and although the book is not intended to be a regional geomorphology almost every principal region is represented It is the Australian-ness that gives the main unifying theme to the book because the essays are of very different types and many aspects of landform study are included Therefore, although the reader is dealing with seventeen different authors and their different approaches, the collection is remarkably successful Most of the essays are between about 10,000 and 16,000 words long, one or two are longer, and the shortest is an interesting little essay by B P Ruxton on "Slopewash under Mature Primary Rainforest in Northern Papua".

The studies are very variable, in that some contain results of new research, while others are more like review articles Moreover, the whole range of disciplines concerned with landform study is dealt with Modern statistical and computer techniques have been used by J G Speight in "Spectral Analysis of Meanders of some Australasian Rivers", and by D S Simonett in his discussion of landslide distribution and its relationship to earthquakes in the Bewani and Torricelli mountains in New Guinea More conventional field geomorphology is represented by C. R Twidale's work on the "Hillslopes and Pediments on the Flinders Ranges" and by R W Galloway's discussion of the pre-, sub- and post-basalt surfaces of the Hunter valley in New South Wales Edmund Gill uses the methods of the Quaternary geologist to unravel the problems of the evolution of the coastline between Warrnambool and Port Fairy in western Victoria

To make any really constructive criticism of the evidence and the conclusions presented in these essays, one would need to know Australia extremely well and to have been working most recently in the areas concerned. Although I am familiar with certain parts of Australia, it is only possible to make general comments on them. As would be expected from the remarks already made, the most interesting and perhaps the most successful essays are those dealing essentially with Australian rather than with more general problems These include particularly the studies of the geomorphological history of the Lake Eyre basin by H. Wopfner and C R Twidale, those dealing with landforms and laterites in both north and south-western Australia (by J Hays and by M J Mulcahy), and that discussing soil periodicity in relation to landform development in south-eastern Australia by B Butler It may be that these studies evoke more especially the nostalgia that affects all who have lived in Australia which is referred to by Professor Hills in his foreword

But it does seem to me that, in the essays where there is a considerable amount of European literature (and American) available, the collection is rather less successful It seems to indicate that the study of landforms in Australia has had to rid itself of geomorphological ideas inherited from other continents before it could really progress This is illustrated by the development of ideas on the glaciation and peri-glaciation in Tasmania, which is the subject of a beautifully clear and succinct contribution by J L Davies The survival of outmoded concepts is also indicated at the end of J. Mabbutt's interesting work on the "Denudation Chronology in Central Australia", in the comment on the "usefulness of the concept of the arid cycle" (page 179); this seems to a European as unnecessary, as the concept of the arid cycle left us long ago Survival is also faintly perceptible in my colleague J N Jennings's persistence in discussing the karst areas of Australia in purely morpho-climatic terms, at a stage when there is a great emphasis, in eastern Europe at any rate, on lithological studies in limestone terrains Nevertheless, it is very good to see the work of the Australian speleologists progressing so well and so much work being done in the Australian karst areas

The two final essays are more in the nature of reviews The first attempts to discuss the factors responsible for the formation of the coastal lagoons in south-east Australia, this work suffers from a certain diffuseness, and it may be, as E. C. F. Bird has himself said, that an attempt at this kind of essay is a little premature in the present state of knowledge. The second of these essays, on the coral reefs of the Australian region by R. W. Fairbridge, is in many ways the most brilliant in the book. Professor Fairbridge's knowledge of coral reefs and of coral limestones is unrivalled, and his application of this to the Australian reefs makes interesting and instructive reading.

Because all seventeen essays are by different people they are in varied styles, but this does not impede the reader greatly. But like "American English", "Australian English" is now written by people whose original language was not English, this leads to much writing in the passive rather than in an active sense, and occasionally to somewhat obscurely written passages like those contained in the interesting work by M. J. Bik on the morpho-climatic zonation in the central highlands of New Guinea.

This collection of essays brings together scientists of many different disciplines—geomorphologists, geologists and pedologists all make contributions. In particular much of the work on Australian landforms stems from the resource surveys of the CSIRO Division of Land Research, illustrating how applied geomorphology has helped the work of the more academic side of the subject and also how Australia has applied landform knowledge to practical ends.

The volume shows signs of having been edited hastily, for there is a long list of corrigenda both to the text and to the diagrams. It was probably better, however, to get the work published rather than delay it too long. It is well illustrated by thirty-six pages of half-tones, each essay containing at least one of them. The diagrams are plentiful and on the whole uniformly drawn. It would have been helpful to have had some of the maps on folding sheets, so that they could be referred to more easily when reading the text.

The book marks a distinct stage and a great development in the knowledge of Australian landforms. It not only introduces the results of new work, but the many references will make the problems of Australian landforms much more familiar to all students of the subject.

M. M. SWEETING

PROTEIN MODELS

Poly-α-Amino Acids

Protein Models for Conformational Studies. Edited by Gerald D. Fasman. (Biological Macromolecules: a Series of Monographs.) Pp. xv+764. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1967.) 275s.

OCCASIONALLY on examining edited books of review or general research articles by, as this dust-cover proclaims, leading authorities, I find that either the authorities are far from leading their fields or they are almost unknown. It is probably the first duty of an editor of such a volume to ensure that the writers are known and respected in their various fields of activity, and in assembling the contributors to this volume Dr Fasman has successfully discharged this duty.

This is the first edited volume of a series on biological macromolecules, the purpose of which, according to the introduction, is a "periodic presentation of critical evaluations of various aspects of a general field". In this case the general field being evaluated concerns the application of physico-chemical techniques to conformational studies of poly-α-amino-acids. Of the thirteen articles presented, one by Silman and Sela on the "Biological Properties of Poly-α-Amino Acids" falls outside the general scope of the volume but nevertheless gives a full and interesting account of the use of synthetic polypeptides in studies of such topics as the action of proteolytic enzymes, the molecular basis of immunogenicity and antigenic specificity and the interaction of poly-α-amino-acids with biological macromolecular systems such as nucleic acids, proteins, viruses and bacteria. Nine of the other twelve articles are by specialists in the various techniques used, one by Mandelkern is a review of the physical studies of poly-L-proline and the remaining two articles are concerned with the factors involved in the conformations and stabilities of polypeptide chains. Both of the last two articles are very long, about 100 pages, the one by Poland and Sheraga is theoretical and applies statistical mechanics to conformational analysis, discussing in particular the non-covalent factors involved in the determination of polypeptide conformations and also the mechanics of the helix→coil transition. The article by Fasman is an exhaustive review of the considerable body of experimental data, as attested by the 457 references quoted, which now exist on the factors (for example, nature of sidechain, length of main chain and solvent system) which determine the conformation of the polypeptide backbone.

Leading research workers have contributed the articles on the specialist techniques and so it need scarcely be said that they are authoritative accounts of the current situation in the various fields. The topics covered are high angle X-ray diffraction of polypeptides (A. Elliott) and low angle diffraction of the different phases in polypeptide/solvent systems (P. Saludjian and V. Luzzati), the usual spectroscopic techniques of the infrared (T. Miyazawa), ultraviolet (W. B. Gratzer), optical rotatory dispersion (J. T. Yang) and circular dichroism (S. Beychok) and the additional fields of light scattering and hydrodynamics (H. Benoit, L. Freund and G. Spach), hydrogen exchange (S. W. Englander) and the dielectric properties of polypeptides in solution (A. Wada). Although the preface states that the "considerable amount of exciting work" forthcoming since 1961 was responsible for the publication of this volume, not all the fields have made significant advances since then and some of them add little new to what was known in 1962. If any of these articles were to be specially mentioned, one might select that by Gratzer on ultraviolet studies of polypeptides which includes not only the basic theory, application and results but also an extremely useful section on the experimental aspects and difficulties of measurements in the far ultraviolet, and the articles by Miyazawa and Englander, who have endeavoured not to re-review work but to present a more critical account of the application of their techniques.

There is little doubt that this volume will be a very useful source of reference to the work completed on poly-α-amino-acids up to the beginning of 1966. There are two criticisms: one is the usual complaint of the time delay, in this case almost two years, which has elapsed since the completion of the articles and their publication. The second criticism is the extremely high price.

E. M. BRADBURY

BIOLOGICAL ULTRASTRUCTURE

Engstrom–Finean Biological Ultrastructure

Second edition. By J. B. Finean. Pp. viii+384. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 120s.

I THINK it would have been wiser, despite Finean's declared attachment to it, if the book had not attempted in a section of forty-seven pages to give before the ultrastructural details themselves a summary of the methods used in their elucidation. To deal adequately in such a short compass with the principles of the operation of the electron microscope and its application in biology, with high- and low-angle X-ray diffraction both as applied to solids and solutions, besides various optical and spectroscopic methods, is impossible A surprisingly balanced introduction to electron microscopy is achieved, but in the section dealing with X-ray diffraction the author tends to set and fall into traps caused by over-brevity There is not the space to distinguish between unit cell and Fourier transforms, it is misleading in relation to diffraction by helical structures to dismiss more complicated diffraction than that from a single helix by "Double and triple chain helices show simple variations of such (single helix) characteristics" Multiple helix systems (for example, α-helix, collagen) usually take the form of coiled-coils and the relationships of their diffraction patterns to simple ones can be complex. Guinier's relationship is quoted for the determination of the radius of gyration of a particle from the X-ray scattering of solutions, but no indication is given of the angular range of its application In a similar manner, in the chapter dealing with principles of molecular structure, I question the value of two pages on quantum mechanics. It is as if the author has tried for the understanding of his readers in the manifold "tricks of the trade" used in ultrastructure determination, I believe instead he should have given sufficient only for the reader to follow the arguments with detailed references to the specialized texts for the details

The book is successful in presenting biological phenomena as "patterns of physical and chemical events organized in space and time" There are sections on proteins, nucleic acids, lipids, carbohydrates, the role of mineral salts and the role of ultrastructure in biology and medicine. In general the structural interpretations are up to date and embrace references until 1966 Occasionally over-brevity gives a slightly misleading impression, for example, the higher order low-angle meridional X-ray diffractions from all dry collagens do not fan out, and besides the order–disorder explanation of Bear for the fanning there is the fibril-shearing mechanism proposed by Tomlin and Ericson Occasionally additional references would be valuable; for example, in connexion with the movement of a cilium or flagellum the author whets the appetite by remarking that plausible theories have been proposed for the control of the movement and its energy requirement, but gives no lead in following it up. There are a few misprints but none to deceive—I wonder whether the reference (page 105) to "Caltech" was intended, but perhaps today everyone knows what it means.

The section of the book dealing with the role of lipids is really a valuable review of the field to which Finean has himself contributed greatly Isolated lipids, lipid interactions and natural lipoproteins are treated most comprehensively and this section merits the space it has been given—the same as the proteins, amino-acid sequences and complete structure determinations notwithstanding

As a broad introduction to molecular biology and ultrastructure research I believe this book to be valuable both at the undergraduate level and especially to the graduate physicist or chemist "converting" to molecular biology I hope that in future editions the space now occupied by "methods" will be given to further structural detail

R E Burge

GENETICS AND BEHAVIOUR

The Genetic Analysis of Behaviour

By P. A Parsons (Methuen's Monographs on Biological Subjects) Pp. viii+174. (London Methuen and Co, Ltd, 1967) 30*s*.

As the author of this biological monograph points out, behavioural traits, when under some degree of genetic control, have a highly significant role in initiating evolutionary change There is also a compelling urge for knowledge in this field as regards our own species, despite the well recognized difficulties

Much of the book is devoted to an exposition of how a quantitative behavioural trait can be analysed from a genetic point of view This includes a scheme of analysis of variance for separating out genotypic and various environmental and interactional effects in a set of inbred strains for a series of environments, this has apparently not been carried out before There is also reference to recent attempts at "locating the polygenes", and a chapter on the evolutionary consequences of variations in mating behaviour. The behaviour that is discussed in greatest detail is that of *Drosophila*, the organism with which the author is most familiar As he mentions, conclusions about mating preferences, the speed with which mating is attempted and the duration of copulation which are derived from laboratory studies may not apply in wild populations of *Drosophila* Still less can findings about the extent and nature of the genetic control of such traits in *Drosophila* be extrapolated to man Yet the difficulties of research with the fruit-fly and the methods that have been devised to overcome them suggest ideas for the genetic study of rodent behaviour, and in turn the analysis of rodent behaviour can be helpful to the human psychologist While the author's approach to man through work on experimental organisms helps to highlight difficulties such as inadequate control of the environment, he also points out the advantages of the more sophisticated methods of biochemical, physiological and psychological investigation that can be applied in man

When he comes to describe and discuss work on rodents and man, Professor Parsons has to rely more heavily on secondary sources, and he does not claim to be anything but extremely selective in his approach to behaviour in man. In some respects, such as the genetics of normal vision and ideas about the evolution of colour-blindness, knowledge may not be as limited as he suspects And despite the difficulties of making any sort of exact statement, there have been continuous attempts in the past few years to apply some of the principles described in the monograph. One thinks of heritabilities calculated for defined behavioural traits such as intelligence, extraversion, drinking habits and schizophrenia, some of them based on natural "wild" populations, and of renewed efforts at assessing environmental variables by means of discordant twins, twins reared apart and fostered or adopted children. This merely shows the potential fruitfulness of a genetic approach in psychology.

The present monograph with its clear exposition of methods, its awareness of the difficulties and its broadly based "attempt at applying evolutionary principles to behaviour" should serve as a useful introduction to its subject.

James Shields

UNRESPONSIVENESS

Natural and Acquired Immunologic Unresponsiveness

By William O. Weigle (Monographs in Microbiology) Pp. x+180 (Cleveland and New York: The World Publishing Company, 1967) $8.

Immunological unresponsiveness can result from the contact of a potential antigen with the immature lymphoid cells of an animal in the perinatal period The concept that this mechanism allows the development of a natural immunological tolerance to autologous body constituents was generated by the observations of Owen on the chimaerism of dizygotic cattle twins; by the speculations of Burnet and Fenner, and by the experiments of Billingham, Brent and Medawar and of Hasek on the consequences of perinatal contact with transplantation antigens Our understanding of the cellular events underlying the induction of immunological unresponsiveness is still uncertain and the importance of the work of Dixon and his colleague Weigle lies essentially in the contributions they made using single protein antigens. This led to a clearer definition of the experimental circumstances involved in the induction, maintenance and termination of the unresponsive state not only in the neonate but also in adult animals The account of this work given by Weigle in his monograph will not provide easy reading for the general immunologist owing to the excessive wealth of experimental detail Nonetheless, the specialist in this field will find it of value to have the data collected in one volume

The author's important studies on the termination of natural or artificially acquired unresponsiveness by cross-reacting antigens feature prominently, his results indicate that antibodies to the tolerance-inducing antigen evoked in this way react only with determinants similar to those present on the cross-reacting antigen but not with determinants to which tolerance has already been established This conclusion has since been elegantly supported by the findings of Paul, Siskind and Benacerraf (*Immunology*, 13, 147, 1967), who studied the termination of unresponsiveness to human serum albumin (HSA) by injection of dinitrophenyl–HSA, the antibodies purified by adsorption to and elution from HSA had a much higher affinity for dinitrophenyl–HSA than for the unconjugated albumin Weigle's caution in referring to "termination of the unresponsive state" rather than "abrogation of tolerance" is thus entirely justified. Demonstration of the latter phenomenon, by providing evidence for the survival of tolerant cells, would have helped to clarify the fundamental question of whether unresponsiveness involves merely the inhibition of lymphoid cells or their elimination

The author clearly considers that in the present state of knowledge extensive theoretical considerations are not warranted, but nevertheless some useful generalizations are made He stresses the need for adequate equilibration of antigen between intra- and extra-vascular spaces for the successful induction of tolerance and directs attention to the fact that all manipulations which facilitate induction of unresponsiveness such as neonatal injection or X-irradiation also provide conditions in which the initial antibody response is depressed, he suggests that antigen can thereby persist at concentrations adequate to inhibit or eliminate the appropriate lymphoid cells The interesting conclusion is drawn that the inhibitory effect of simultaneous injection of the tolerogenic antigen on the termination of unresponsiveness by cross-reacting antigen provides a mechanism by which the body is protected from the formation of autoantibodies by cross-reacting microbial antigens. Where the concentration of a body constituent in the circulation is low, one could expect, and indeed may find, formation of autoantibodies in response to such exogenous antigens Weigle speculates that this may be one of the ways in which autoimmune diseases arise, but could have been more explicit in relating this hypothesis to specific clinical disorders The relevance of tolerance induction in the adult to problems of transplantation should perhaps have been discussed in a book on this subject, and in this context the possible implications of Mitchison's observations on "low dose tolerance" would seem to merit greater emphasis I M Roitt

INSECT PHYSIOLOGY

Insects and Physiology

Edited by J W L. Beament and J E Treherne. Pp viii + 378 + 34 plates (Edinburgh and London : Oliver and Boyd, Ltd., 1967) 130*s*

The greatness of a man of science is not measured by the number of his pupils, the weight of his publications or even the number of times his name appears in textbooks Professor V B Wigglesworth would qualify on any of these counts, but none would do him justice The true measure of greatness is the extent to which others have been able to build, on foundations securely laid, a structure of greater beauty than the founder himself could have created

This book is a collection of articles specially written on the main theme of Wigglesworth's 1948 Croonian Lecture—the suitability of insects for the study of physiology The authors are all people who have worked at least for a time in his unit in Cambridge As is almost inevitable in such a publication, the standard varies widely and it is depressing to note that the main flowering of ideas seems at present to be taking place on the other side of the Atlantic. The four essays from Western Reserve University are all extremely stimulating and so are five others from elsewhere in the United States and Canada, many of these record important new experimental results By contrast (and apart from those by Maddrell and Weis-Fogh), the articles from Cambridge are mainly historical or repeat discussions already published elsewhere. Migration appears to be desirable for the health of this species, though the quality of the writing by Miller shows that it need not be to another country

Wigglesworth has worked on insects for most of his life, but he has always tried to relate his discoveries to the rest of physiology Another distinction can be made between the different articles in this volume by the extent to which the authors follow their mentor's example Most of the Americans show a clear appreciation of the fact that insects are merely one of the types of animal and thus strengthen their advocacy of this particular biological material for the solution of their problems. Some of the local products seem to be entomologists first and physiologists second, and a few do not appear even to be familiar with the recent entomological literature

The main subjects discussed are morphogenesis, neurosecretion, the growth and organization of the sensory and central nervous systems and the structure and permeability of the cuticle. The foundations for each of these branches of insect physiology were laid by Wigglesworth. The reviews by Weis-Fogh on flight metabolism, by Berridge on ion and water transport and by Davey on reproductive physiology are also important, though drawing only general inspiration from his writings, these three bring out very well the value of studies on insects for the general physiologist Although, as Miller says, "reviews and hypotheses, like nappies, must be freely disposable", many of these articles will certainly remain in use for some time and many of the suggestions made by the authors will justify several passages through the clarifying laundries of the scientific world I fear that because the word "insects" is printed large and the word "physiology" small on the dust cover and spine, many physiologists will miss the opportunity offered to them, for the crusade launched by Wigglesworth in 1948 still hardly affects the security of the great para-medical laboratories Perhaps David Smith puts his finger on the reason for this when he writes that, for all the many advantages of insects, "their small size hampers correlated structural and biochemical studies involving the separation of subcellular fractions" Certainly the attempts made in this volume to jump on the DNA/RNA band-wagon reveal a singular lack of secure footholds

I must regretfully note certain signs of carelessness in printing and editing There are minor misprints in nearly every article and in several places the initial letter of a line has fallen out, once the initial words on two adjacent lines are interchanged And surely one contributor should not be allowed to mis-spell the name of another in his text and list of references! For all this, the volume is a worthy tribute to a great man and one may hope that this evidence of the progress made by some of his pupils and collaborators will be to him both a source of satisfaction and an encouragement to continue his own researches, which are by no means at an end

J W S Pringle

Announcements

Applications are now invited for the 1968 Drummond Prize, an annual prize of £250 awarded for research in the field of nutrition. The prize, which is for research undertaken by persons normally resident in Great Britain, is open to those who have not reached the age of 35 by the closing date Further information can be obtained from Mr D S Miller, Honorary Secretary. Nutrition Society, Queen Elizabeth College, London W8

The American Microchemical Society has created a fund to commemorate the work of the late Dr A A Benedetti-Pichler, and an award will be made to an individual who has made outstanding contributions to the practice or teaching of microtechniques Nominations are now being sought and further information can be obtained from Dr Michael Cefola, Department of Chemistry, Fordham University, New York, NY 10458

Applications are now invited for the 1968 Langley Memorial Prize, founded to commemorate the work of Dr W H Langley, principal medical officer, southern Nigeria The prize, value £21, is awarded triennially for the best paper on one of the following subjects Tropical Medicine or Surgery, Tropical Hygiene and Sanitation, Tropical Entomology and Parasitology Further information can be obtained from the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street London WC1

Meetings

Modern Chemistry in Industry, March 11–14, Eastbourne (Honorary Secretary, 14 Belgrave Square, London SW1)

Brain Research and Human Behaviour, March 11–15, Unesco House (P Dell, Ibro/Unesco, Place de Fontenoy Paris 7^e)

The Council of the European Organization for Nuclear Research has planned four sessions during 1968 to be held on the following dates March 14, June 19–20, September 25–26, December 18–19

Physical Properties of Liquids and Gases for Plant and Process Design, March 20–21, Ministry of Technology's National Engineering Laboratory, East Kilbride, Glasgow (Mr S W Turner, BP Chemicals (UK) Ltd , Bo'ness Road, Grangemouth, Stirlingshire)

Optimization, March 25–28, University of Keele (The Secretary and Registrar, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex).

Mechanical and Thermal Properties of Ceramics, April 1–2, US National Bureau of Standards (J B Wachtman, Jun , Rm A359, Materials Bldg , National Bureau of Standards, Washington, DC 20234)

Wind Effects on Buildings and Structure, April 2–4, University of Technology, Loughborough (Mr J Charles Department of Transport Technology, University of Technology, Loughborough, Leicestershire)

Erratum In the article by Professor Herbert Dingle in the issue of January 6 (*Nature*, 217, 19, 1968), one paragraph was unfortunately garbled in transmission by telephone The first complete paragraph in the right-hand column of page 20 should read as follows

The letters of Dr Barrett[6] and Mr Fullerton[7] reveal elementary misconceptions Barrett writes "for *A*, these two clocks are not synchronized" Synchronized clocks are not synchronized for *A* or for *B*, they are simply synchronized The process is experimental if the readings satisfy the condition $T_3=2T_2-T_1$, given in my article, the clocks are synchronized absolutely Barrett confuses clock-readings with the times at which the clocks have those readings the same reading is correct, fast or slow, according to the co-ordinate system chosen, but the reading is absolute Clock-readings alone are involved in my disproof of special relativity That is why Einstein rightly concluded that his theory required one clock to work absolutely more slowly than the other Fullerton refers to an observer who "synchronizes *A*, *B* and *H* to zero but not *N*" Clocks are not synchronized to one reading, synchronized clocks give a common reading for every event *B* cannot be synchronized with *A* and *H*, for it moves with respect to them If Fullerton means only that these clocks read zero at the event E_0, then so does *N*, but the fact is trivial

Erratum In the communication "Semi-annual Variation in Thermospheric Density" by Reginald E Newell (*Nature*, 217, 150, 1968) in the twenty-second line of the third paragraph $K_p \leqslant 5_0$ should read $K_p \geqslant 5_0$

Erratum In the communication "Interaction between Model Compounds of Actinomycin *D* and DNA Physicochemical Studies" by F Ascoli, M Savino and A M Liquori (*Nature*, 217, 162, 1968), the last sentence of the fifth paragraph should read "The values so obtained are 1 125 and 1 350 which are of the same order of magnitude as those obtained for 3,4-benzpyrene"

Erratum The bibliographical details of the review of the books by G K Batchelor and Frank Chorlton (*Nature*, 217, 199, 1968) should have been as follows

An Introduction to Fluid Dynamics

By G K Batchelor Pp xviii + 615 (London Cambridge University Press, 1967) 75*s* net, $13 50

Textbook of Fluid Dynamics

By Frank Chorlton Student's Paperback edition Pp xiv + 399 (London D Van Nostrand Company, Ltd , Princeton, N J D Van Nostrand Company, Inc , 1967) 35*s*

On page 204 of the same issue the ninth of the reports and publications should be Freedom of Action in a Mechanistic Universe

CORRESPONDENCE

New Era for Salk Institute?

Sir,—There is one factual error in the article about the institute in the December 9, 1967, issue of *Nature* (216, 961, 1967), and one passage that deserves comment

The physical plant of the institute has not cost twenty million pounds, as the article states, but approximately twenty million dollars

The statements in the article which refer to the "past two years" might be interpreted as a pejorative personal reference to the past President, Dr Augustus B Kinzel whose long-time performance in many positions has earned him a reputation as a very strong administrator Your readers may therefore be interested to know that the trustees of the institute approved a resolution which contained the following remarks

" Dr Kinzel contributed importantly to the administration of the Institute during a period when there were complex matters of concern to the Fellows and the Trustees During his tenure, the scientific work of the Institute has made notable progress and the broad interests of the Institute have been clearly advanced

"Steady perseverance and resourcefulness have characterized Dr Kinzel's work for the Institute . "

Yours faithfully,

Jonas Salk

Salk Institute for Biological Studies,
San Diego

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, January 29

ROYAL INSTITUTION (at 21 Albemarle Street London, W1), at 5 30 p m —Professor Julius Sumner Miller "What is Physics?" (Lecture for Fourth orm Boys and Girls from Schools in London and the Home Counties To e repeated on January 30, 31 and February 1)

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT IEE/IERE EDICAL AND BIOLOGICAL ELECTRONICS GROUP (at the Institution of Elecical Engineers, Savoy Place, London, WC2), at 6 p m —Colloquium on Diathermy"

INSTITUTION OF MECHANICAL ENGINEERS, MEDICAL ENGINEERING WORKNG PARTY (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m — Discussion Meeting on "The Physics and Medical Applications of Lasers"

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompon Hospital, London, SW3), at 6 15 p m —Dr J R May "The Chemoherapy of Non-Tuberculous Respiratory Infections" *

Tuesday, January 30

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 1 20 p m —Mr E W Foster "The ennine Way" *

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2) t 5 30 p m —Discussion Meeting on "Electrical Breakdown in Magnetic ields" opened by Mr L King, Mr N L Allen and Mr K A Bunting

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at Savoy Place, London, WC2), at 5 30 p m —Mr H Nicholson "Computer Simulation of Boilers and Turbo alternators"

UNIVERSITY OF LONDON (at Chelsea College of Science and Technology, Manresa Road, London, SW3), at 5 30 p m —Mr H G Gilson "The Biological Problems of Estuary Barrage Reservoirs" *

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Dr G F M Russell "Anorexia Nervosa Psychological, Endocrine and Nutritional Aspects" (Sixth of fifteen lectures on "The Scientific Basis of Medicine" organized by The British Postgraduate Medical Federation)*

INSTITUTION OF MECHANICAL ENGINEERS, RAILWAY ENGINEERING GROUP (at 1 Birdcage Walk, Westminster London, SW1), at 6 p m —Discussion Meeting on "U I C Standards and Design Limitations which would Result from the Channel Tunnel"

INSTITUTION OF THE RUBBER INDUSTRY LONDON SECTION (at the Eccleston Hotel, Victoria, London, SW1), at 6 p m —Mr H Walton "Critical Path Analyses", "Ozone Resistance of Elastomers" by a speaker from Dupont

Wednesday, January 31

ROYAL INSTITUTION, HISTORY OF SCIENCE DISCUSSION GROUP (at 21 Albemarle Street, London, W1), at 1 p m —Mr H G Frost "The Nineteenth Century Science Text Book Its Role in the Application of Science" *

UNIVERSITY OF LONDON (at the Royal Postgraduate Medical School, Du Cane Road, London, W12), at 2 p m —Dr M S Dunnill "Measurement in Histology" *

SOCIETY FOR ELECTROCHEMISTRY (at the Royal School of Mines (Room 53), Imperial College of Science and Technology, London, SW7), at 2 30 p m — Lord Wynne-Jones "Chemistry at Electrodes" (Inaugural Address)

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W1), at 5 p m —Mr N E Butcher "The Earliest Known English Colour-Printed Geological Maps" (Demonstration), Mr P Lambort "Reproduction of Old Geological Maps Produced by Colour Photography" (Demonstration), Dr A C Bishop, Dr J D Bradshaw, Dr J T Renouf and Mr R T Taylor "The Stratigraphy and Structure of Part of West Finistère, France" (Paper)

UNIVERSITY OF LONDON (in the Physiology Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Dr E J Furshpan (Harvard Medical School) "Low-Resistance Intercellular Junctions" *

Thursday, February 1

ROYAL SOCIETY (at 6 Carlton House Terrace, London, SW1) at 4 30 p m —Professor D Gabor, FRS, and Mr G W Stroke "Theory of Deep Holograms", Mr J H Thomson and Mr J E B Ponsonby "A Method of Obtaining High Resolution Radar Maps of the Moon by Two Dimensional Aperture Synthesis Using a Single Aerial"

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi London, WC2), at 5 15 p m —Mr Keith R Harding "Mining Development in Australia" (Henry Morley Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Optimisation of Traffic Throughput" opened by Mr D J Lyons.

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street London, WC1), at 5 30 p m —Professor R W Gilliatt "Experimental Peripheral Neuropathy" (Seventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

UNIVERSITY OF LONDON (at the Royal College of Surgeons Lincoln's Inn Fields, London, WC2), at 5 30 p m —Dr A R de C Dencock "Medical Problems of Underwater Diving" *

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, SE1) at 6 p m —Mr G Mann "Methods of Regulating the Carbon Dioxide and Oxygen Concentrations in Controlled Atmosphere Stores for Fresh Produce"

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, EDUCATION GROUP (at 8–9 Bedford Square, London, WC1), at 6 p m —Mr C F Davidson "Satellite Communication Systems and the Diverse Engineering Techniques Which They Require"

INSTITUTION OF MECHANICAL ENGINEERS, TRIBOLOGY GROUP, and the INSTITUTION OF METALLURGISTS (at the INSTITUTION OF MECHANICAL ENGINEERS, 1 Birdcage Walk, Westminster, London SW1), at 6 p m — Discussion Meeting on "Metallurgy is the Most Important Discipline in Tribology"

Friday, February 2

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street London, W1) at 1 p m —Dr J B Birks "The Pyrene Excimer" *

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, WC2), at 2 30 p m —Colloquium on "M O S T 's for Analogue Switching"

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, WC2), at 5 30 p m —Mr V S Ramsden and Mr R R Booth "The Digital Computer Representation of Induction Machine Transient Performance"

Saturday, February 3

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum London Road, Forest Hill, London, SE23), at 3 30 p m —Mr K M Harris "Living in Darkness—Biology of Caves" *

Monday, February 5

INSTITUTION OF ELECTRICAL ENGINEERS ELECTRONICS DIVISION (at Savoy Place, London, WC2), at 5 30 p m —Mr F E Williams, Mr F A Wilson and Mr K A T Knox "Future Trends in the Design of Subscribers' Telephone Instruments"

INSTITUTION OF ELECTRICAL ENGINEERS, JOINT PROFESSIONAL GROUP (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Specification of the British Electrical Indicating Instrument" opened by Mr L B S Golds

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Fine Chemicals Group, at 14 Belgrave Square, London, SW1), at 6 30 p m —Professor R C Cookson "Some Aspects of Photochemistry"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT LECTURERS or LECTURERS (2) in the DEPARTMENT OF PHYSIOLOGY—The Registrar, University College, Cathays Park, Cardiff (January 31)

RESEARCH ASSISTANTS (2) IN GEOLOGY to complete the team of six engaged in the resurvey of the Teignmouth One inch Geological Map (Geological Survey Sheet 339) under a contract with the National Environment Research Council—Professor S Simpson, Department of Geology, The University, North Park Road, Exeter, Devonshire (February 2)

HARRIS CHAIR OF PHYSICS—The Secretary, The University, Dundee Scotland (February 10)

LECTURER or ASSISTANT LECTURER (mathematician with research interests in any branch of pure mathematics or mathematical statistics) in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of Swansea, Singleton Park, Swansea (February 10)

UNIVERSITY LECTURER in either SOCIAL PSYCHOLOGY or SOCIOLOGY—The Secretary of Faculties, University Registry, Oxford (February 10)

LECTURER in APPLIED MATHEMATICS—The Secretary, Trinity College, University of Dublin, Dublin 2, Republic of Ireland (February 12)

EXPERIMENTAL OFFICER IN THE DEPARTMENT OF METALLURGY for duties in electron micro-probe analysis, mainly for work on meteorites—The Registrar, The University of Manchester, Manchester, 13, quoting Ref 2/68Na (February 14)

EXPERIMENTAL OFFICER (preferably with experience with X-ray equipment, high vacuum equipment or electronic instrumentation of any kind) in the DEPARTMENT OF GEOLOGY for the maintenance and operation of a geoscope electron probe microanalyser and an electron microscope—The Registrar, The University, Manchester 13, quoting Ref 8/68/Na (February 14)

LECTURER (with medical qualifications registrable in the United Kingdom) IN ANATOMY—The Registrar, The University, Manchester, 13, quoting Ref 3/68 (February 14)

ASSISTANT LECTURER/LECTURER (with an interest in animal behaviour) IN PSYCHOLOGY—The Secretary (NAT), University of Stirling, Stirling Scotland (February 15)

SENIOR RESEARCH OFFICER (with a degree in agricultural science, rural science or equivalent, and several years of postgraduate experience in animal husbandry research) at the Agricultural Research Institute, Wagga Wagga, New South Wales, Australia, to formulate and supervise animal husbandry research programmes in the southern wheat belt and southern tablelands of New South Wales—The Recruitment Section, New South Wales Government Offices, 56 Strand, London, WC2 (February 16)

LECTURER IN NEUROSURGERY at the Institute of Neurological Sciences, Glasgow—Secretary to the University Court, The University, Glasgow (February 17)

LECTURER (suitable medical or science graduate) in the DEPARTMENT OF BACTERIOLOGY AND IMMUNOLOGY at the Western Infirmary—The Secretary of the University Court, The University, Glasgow (February 17)

ASSISTANT LECTURER or LECTURER (with interests in either fluid dynamics or computation) in the DEPARTMENT OF MATHEMATICS—The Deputy Secretary, The University, Southampton (February 23)

RESEARCH FELLOW in the DEPARTMENT OF ELECTRICAL ENGINEERING for research into cryogenic cable systems—The Deputy Secretary, The University, Southampton (February 23)

CHAIR OF PSYCHOLOGY at Bedford College—The Academic Registrar (A) University of London, Senate House, London, WC1 (February 29)

LECTURER or ASSISTANT LECTURER (preferably with a special interest in immunology) in the DEPARTMENT OF BACTERIOLOGY AND VIROLOGY—The Registrar, The University, Manchester, 13, quoting Ref 4/68

POSTDOCTORAL FELLOW IN CHEMISTRY for research on Lewis acid-base reactions in the gas phase—Professor A F Trotman-Dickenson, University College of Wales, Aberystwyth

RESEARCH ASSISTANT in the DEPARTMENT OF FORENSIC MEDICINE to assist in a programme of research into the development of rapid methods of toxicological analysis—Dr H V Street, Department of Forensic Medicine, University Medical Buildings, Teviot Place, Edinburgh, 8, Scotland

SCIENTIFIC INFORMATION OFFICER (preferably with a botanical or agricultural degree, or knowledge of or aptitude for foreign languages, and ability to write good English) for duties which include the preparation and editing of abstracts for the journal *Plant Breeding Abstracts*, the classification of biological literature, and dealing with scientific enquiries—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50.50**	**£13 10 0**
6–11	**£12.15 0**	**$44 50**	**$48.30**	**£12 15 0**
12 or more	**£12.0 0**	**$42 50**	**$46.00**	**£12 0.0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A)

Remote Sensing of Environment

AN INTERDISCIPLINARY JOURNAL

Published quarterly Volume 1, Number 1, Summer 1968

Editor-in-Chief. DAVID S. SIMONETT

The Journal will publish papers of both research and expository type dealing with the use of remote sensor images and other remotely sensed data for scientific and practical applications in the areas indicated below

Editorial Board

Agriculture and Forestry	ROBERT N COLWELL *145 Mulford Hall* *University of California* *Berkeley, California 04720*	DAVID M GATES *Director, Missouri Botanical Garden* *St Louis, Missouri 63110*

PIETERMARITZBURG
WATTLE RESEARCH INSTITUTE

Applications are invited for the post of DIRECTOR OF THE WATTLE RESEARCH INSTITUTE attached to the University of Natal, Pietermaritzburg, South Africa The fields of research include silviculture, genetics and plant breeding, plant physiology and pathology, entomology, and phytochemistry Experience in research and its direction and administration is necessary The Director is responsible also for public relations and extension services and experience in these would be added qualifications for the post

The salary is on the scale R6 600 by R300 to R7,500 and the appointee will have the status of Professor in the University, with a seat on the University Senate Membership of the Associated Institutions Pension Fund and of the Statutory Organizations Medical Scheme is compulsory The appointment will be, in the first place, for a probationary period of one year (Note At the new rate of exchange R1 716=£1 sterling)

Further particulars, conditions of service, and application forms, may be obtained from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications must be lodged in South Africa and London not later than March 15, 1968 (305)

UNIVERSITY OF GLASGOW
LECTURESHIP IN MECHANICAL ENGINEERING

Applications are invited for a Lectureship in the Mechanics and Mechanism Group of the Department of Mechanical Engineering of the University The person appointed will be expected to contribute to the teaching and research work of the Department in the field of Dynamics A particular interest in Mechanical Vibration and/or Control Systems will be an advantage Applicants should possess a good Honours degree in Mechanical Engineering, or in a related subject The salary will be in range £1,470 to £2,270 (bar) to £2,630 per annum, with F S S U membership Prior experience of teaching or research is not essential if the successful applicant does not already have a higher degree he will be expected to work towards one

Applications (eight copies) should be lodged, not later than February 10, 1968, with the undersigned, from whom further particulars may be obtained

ROBT T HUTCHESON,
Secretary of the University Court
(318)

THE AGRICULTURAL RESEARCH COUNCIL has the following vacancies for ASSISTANT EXPERIMENTAL OFFICERS or EXPERIMENTAL OFFICERS at their RADIOBIOLOGICAL LABORATORY

A CHEMIST to assist in studies of soil and the availability of nutrients to plants Radiochemical methods and neutron activation analysis figure largely in this work Experience in either analytical inorganic chemistry or radiochemistry is desirable

B BIOLOGIST to assist in laboratory studies of factors affecting the growth of plant roots and their absorption of inorganic nutrients Previous experimental experience in plant physiology is desirable

Minimum qualifications for both posts Pass degree or, if under 22, G C E "A" level in two subjects, or equivalent Salary in scale A E O £584 (at age 18) to £1,243 (maximum starting salary at age 26, or over, £1,017), E O £1,365 to £1,734

Apply, with names of two referees to the Secretary, Agricultural Research Council Radiobiological Laboratory, Letcombe Regis Wantage, Berkshire by February 9 1968 (357)

CANADA

(RESEARCH OPPORTUNITY)

INORGANIC
or
PHYSICAL-ORGANIC CHEMIST

Position for a Ph D or M S (Ph D preferred) Academic training or research experience in asbestos fibres, cementitious materials, asphalt or similar field The work will involve both basic and applied research programmes

- Our new laboratory is located in the Sheridan Park Research Community just west of Toronto, and this position will be attractive to those wishing to work in an atmosphere of research and development

Send resumes by airmail to

Personnel Officer,
Ontario Research Foundation,
Sheridan Park,
Ontario, CANADA

(387)

ICI

GRADUATE CHEMIST

I C I 's Industrial Hygiene Research Laboratories, which are located in pleasant surroundings at Alderley Edge just south of Manchester, require a Graduate Chemist for the investigation of the metabolism of chemical substances in biological systems Candidates, either male or female, should have an honours degree, although a lower qualification with suitable experience would be considered

Progressive salary plan housing assistance and help with removal expenses for married men

Applications and inquiries to —

O. B. Sayer, Assistant Staff Manager, Imperial Chemical Industries Limited, Head Office Services Department, Fulshaw Hall, Wilmslow, Cheshire. (297)

NATIONAL AGRICULTURAL ADVISORY SERVICE
MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

SCIENCE SPECIALISTS

At least ten posts for Chemists and Biologists to work as specialist advisers in animal nutrition, bacteriology, plant pathology, and soil science, and at least one post for an Analyst concerned with the testing of soil, feeding-stuffs, plant and other materials Appointment to (i) Grade III, or (ii) Grade IV according to age, qualifications, and experience

Age at least 26 for (i) or at least 20 for (ii)

QUALIFICATIONS degree (or equivalent or higher qualification) in an appropriate agricultural or natural science In addition for Grade III posts normally at least three years' relevant experience Car driving essential for most posts

FINAL YEAR STUDENTS MAY APPLY

SALARY (national) Grade III £1,396 to £2,193, Grade IV £899 to £1,277 Starting salary may be above minimum in both cases Non-contributory pension Promotion prospects

WRITE to Civil Service Commission, Savile Row, London W 1, for application form, quoting 296/68 Closing date February 15, 1968

NATURE Volume 217
FEBRUARY 3, 1968

Hornet's Nest for Coal

THE continuing pantomime of public declarations about the fuel to be used for the aluminium smelting plant which Alcan wishes to build in the United Kingdom has brought to the surface a great many important issues of principle in the conduct of the business of the nationalized industries and a great many anomalies in the British Government's attempt to organize a co-ordinated fuel policy (see page 398). There seems to be no doubt that Alcan has offered to build an aluminium smelter based on coal rather than electricity from the national grid because the National Coal Board has been able to offer it cheap coal and stable prices. The immediate issue is whether this offer is realistic.

From the way in which Sir Ronald Edwards has now informed the coal board that he does not wish to accept the offer of cheap coal at 3.25*d* a therm for the new electricity generating station at Seaton Carew in north-east England, it is plain that the coal board's offers are not universally beguiling. Quite properly, what the Central Electricity Generating Board is anxious about is the prospect that coal prices will steadily increase during the lifetime of a power station built now to use coal as fuel. Evidently the coal board has not felt able to give the electricity board the kind of assurance which Alcan appears to have got. Nobody should be surprised that both the steel and electricity industries are up in arms at what seems to them to be unfair discrimination.

In practice, of course, it is only possible for the National Coal Board to sell coal on long-term contracts at prices less than 4*d*. or even 5*d*. a therm by counting on the elasticity afforded within its price structure by the other large customers for coal and by the fact that in the last resort the Government will have to bail it out of trouble. If, for example, the coal board were to guarantee a fixed low price for coal for an aluminium smelter, it would have to seek to recover the increased costs of mining that coal from its other customers, chiefly the electricity and steel industries. But is it proper for a nationalized industry to decide for itself which customers should pay what? Is it proper that it should first of all persuade the Government that the electricity industry should burn more coal than it wishes to do and then, without prior consultation, arrange things in such a way that coal will cost more than it should?

The trouble, of course, is that in a situation in which one large organization sells to a handful of other large organizations, fixing the proper selling price is a process which has more in common with the negotiation of a diplomatic treaty than the processes by which other market prices are fixed. The difficulty is exacerbated in the present circumstances by the common understanding, no doubt as vivid among the officials of the coal board as anywhere else, that the British coal industry is already supported to a very large extent by the determination of the British Government to see that it shall not collapse too quickly. If the coal board were to sign a contract with a would-be aluminium smelter which turned out to be an embarrassment in the years ahead, it is unthinkable that it would be allowed to default on the obligations it had undertaken. The Government, in the last resort, would be compelled to step in.

What, in these circumstances, should the Government do? Perhaps the most simple prescription for action in the months immediately ahead is that the Ministry of Power should make sure that the freedom which the National Coal Board is anxious to enjoy should somehow be accompanied by a full share of responsibility. The trouble in present circumstances is that the coal board—and many of the other nationalized industries as well—is able to pretend to commercial freedom in some of its activities while relying on an implicit guarantee that the Government will step in if commercial policies are wrong. Where the coal board is concerned, the Government has been unreasonably indulgent in recent years. For example, at a time when the coal board has been producing more coal than it could sell, the Government has provided the funds with which to finance an increased accumulation of coal stocks. By the same test, the rate at which the coal board is expected to earn a surplus on the capital employed in this industry is less than that of the other nationalized industries. It would obviously be an enormous benefit if the Ministry of Power could now return to its excited talk of only a few months ago and somehow arrange that the coal board were exposed to some of the harsher realities of the world in which it is seeking to live so freely. For one thing, it would obviously help enormously to create a sense of realism among the officials at the coal board if the industry were required to raise at least a part of the money needed to finance its development in the public market and not from the British Treasury. Where customers are concerned, it would obviously help if the large industries which fear from time to time that they are being asked to pay more for coal than is economically possible were allowed once more to import this from abroad.

But if this prescription is likely to help the coal board to put its house in order and cease being an embarrassment to the other nationalized industries and the Government as well, is there not a case for asking that similar rules should apply across the board? Certainly, the electricity industry itself would probably welcome a chance to finance some of its undertakings from sources other than the British taxpayer—at the very least this would provide a degree of flexibility which is at present lacking By the same test, the electricity industry should no longer be required to negotiate with the Government before deciding to build a power station of one kind or another

Smelting at Home

The British Government wants to save imports by establishing an aluminium smelting industry in Britain So much is clear But the idea is now so complicated by wrangling that it seems unlikely to be carried through without ill-will Internationally, the running has been made by Mr Kare Willoch, the Norwegian Minister of Commerce, who said that the move to establish aluminium smelting in Britain was both illegal and immoral and defied both the EFTA convention and the spirit of free trade In Britain, the objections are likely to be less easy to brush aside

The trouble is that Alcan, one of the aluminium companies which wants to build in Britain, has allowed itself to get involved in a long-standing row between the electricity generating boards and the National Coal Board The coal board, which claims that it is still possible to generate electricity as cheaply by burning coal as uranium, has persuaded Alcan to base its tender on a coal-fired generating station Although it would clearly be more attractive to Alcan to have the whole smelter complex under its own control (rather than sharing the output of a large nuclear station, which was the original intention), it has been generally assumed that the most compelling argument has been a promise by the coal board to supply coal at knock-down prices

Both the coal board and Alcan have refused to reveal the price that has been agreed for the coal It is, however, quite possible to calculate this Alcan has agreed to take 1 million tons of coal a year from the north-east coal-field, where the cost of coal in 1967 was an average of £5 32 a ton, according to the annual report of the coal board At this price, Alcan's annual bill would be £5 3 million, even if transport costs were ignored But Mr John Elton, managing director of Alcan in Britain, has said that power costs amount to no more than 15 per cent of production costs Aluminium ingots sell at about £228 per ton and, to make the investment worthwhile, Mr Elton will have to produce ingots at about £200 per ton For a 120,000 ton a year plant, this means annual production worth £24 million Fifteen per cent of £24 million is £3 6 million, far less even than the cost of fuel if Mr Elton were buying at the going rate It is clear that he can be paying no more than £2 8 to £3 million a year for coal, equivalent to 3·1*d* per therm at the smelter This is very markedly less than the 5*d* per therm paid by the generating boards, or the 4 6*d* per therm paid by the National Steel Corporation, both of which are much larger customers

Even if the deal is approved, Invergordon seems an odd place to choose for the smelter, particularly as it will involve the transport of coal by sea from the north-east of England Invergordon, it can be argued, is a development area and is thus a candidate for development grants, but so is the north-east In principle it would be most sensible of all to build the smelters where the ore, bauxite, is mined—in Jamaica, among other places At present bauxite is converted to alumina in plants in Jamaica and is then carried by sea to the smelters elsewhere in the world.

Slower Growth for Universities

The publication last week by the University Grants Committee of the grants to individual universities enables a preliminary assessment to be made of the way in which universities are likely to develop over the next five years Fig 1 shows the total support provided by the University Grants Committee to the universities in the years between 1957 and 1972 Fig 2, which takes the University of Birmingham as a particular example, shows the same pattern What the curves do is to confirm an impression that the years of really rapid growth lie between 1963 and 1968, and are now coming to an end Beyond 1968 there is evidence of a slackening of support, and it looks as if the growth will return to much the same rate as prevailed before 1963 On this rather pessimistic argument, the stimulation of support for universities which was achieved by the publication of the Robbins Report was little more than a temporary phenomenon

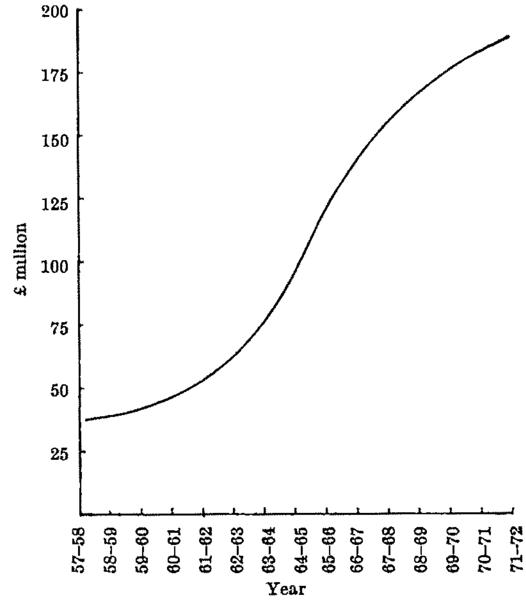

Fig 1 Support by UGC to British universities, 1957–72.

What is potentially more alarming—to scientists, at least—is that of the more modest increases which are promised to the universities in the next five years, the greater part will be devoted to subjects other than science and technology In this, as in other things, the UGC has been swept along by the tide Although Sir John Wolfenden is no Canute, he and his committee do seem to have made some efforts to resist—they provided for a small expansion in science and technology, although the evidence is that the total numbers of students coming forward will actually decline for the next few years The UGC is clearly terrified that if the swing away from science should reverse itself, and the attractions of social science become less compelling to schoolchildren, it is going to be left high and dry This is why it has provided for an increase in science places, although the evidence is that some of them will be left empty, or filled by students less able than their contemporaries in other departments.

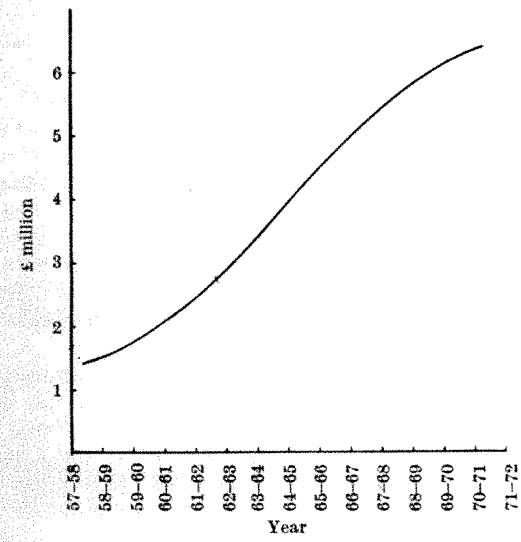

Fig. 2. Support by UGC to Birmingham University, 1957–72.

For the first time, the UGC report includes an interesting survey of the costs of producing graduates in a variety of disciplines. The figures, reproduced below, show how much it costs to produce a graduate in each of the disciplines listed, but do not include the costs of administration, libraries and maintenance of buildings. These costs add up to an additional £260 per student.

ACADEMIC YEAR, 1966–67

	Average Unit Cost	*Average Staff/ Student Ratio*
	£	1 :
Arts	276	9·8
Social Studies	255	11·3
Education	261	12·5
Biological Sciences	518	8·7
Physical Sciences	376	11·3
Technology	425	11·3
Medicine		
(*a*) pre-clinical	647	8·2
(*b*) clinical (excluding postgraduate institutes)	790	5·9
Dentistry	778	5·6
Veterinary Science	1,136	4·6
Agriculture	497	7·8

Sonic Booms and Superbooms

A PROGRESS report on research into sonic booms has been carried out by a sub-committee of the Committee of the US National Academy of Sciences on SST–Sonic Boom (*Generation and Propagation of Sonic Boom*, National Academy of Sciences. Obtainable in Britain from Universal Subscription Service, Ltd., 4 Footscray Road, London, SE9. 25*s*.). The sub-committee, which was chaired by Dr R. L. Bisplinghoff, professor of aeronautics at MIT, held out no hope for an immediate or dramatic improvement in noise generation.

Progress in supersonic aerodynamics has been such that sonic boom overpressures on the ground can now be accurately predicted to within margins of 10 per cent. But this is only for aircraft flying at constant speed, height and direction and over a quiescent atmosphere. Atmospheric inhomogeneities, such as those caused by temperature variations, wind shears and turbulence, exert a complex effect on the propagation of shock waves which at present is poorly understood. Topographic features and seasonal variations in atmospheric turbulence also exert profound influences on the sonic boom waves that reach the ground, and here again further research is needed.

The phenomenon of "superboom" occurs when shock waves from more than one point of the flight path reach the observer at the same time. This can happen when a supersonic aircraft changes speed or direction, with the result that propagated shock waves are momentarily focused at a single point. Current theory can predict the location of a superboom on the ground but not the size of the pressure wave. The sub-committee is dissatisfied with current investigation into superboom effects, and it considers that more flight and laboratory tests are necessary.

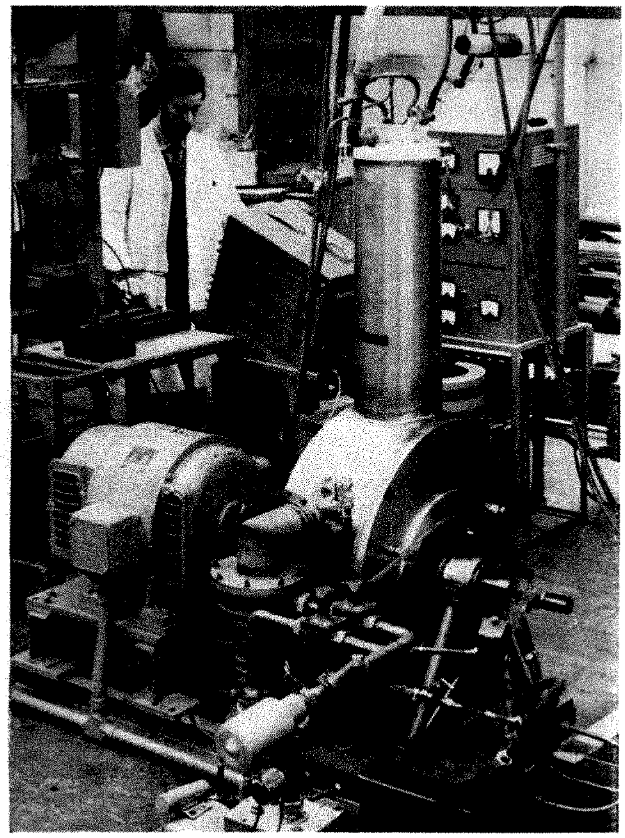
Studies of aircraft design aimed at minimizing sonic boom effects are of prime importance, but the designs so far tested have been relatively conventional. The sub-committee urges that less conventional configuration studies be undertaken in the future. The better radiation characteristics of such fuels as liquid methane or hydrogen hold the possibility of increased propulsion efficiency and possible reduction in sonic boom levels; this is another topic that would merit further attention.

At ground level, little is known about the exact features of the sonic boom which make it undesirable both to animals and to the stability of buildings. The record of the pressure wave as a sonic boom hits the ground, known as its signature, varies both with the type of aircraft and the prevailing conditions. Further research needs to be devoted to determining which parameters of the signature are responsible for damage to human sensibilities on the one hand and to buildings on the other.

It is clear that a large number of problems remain to be solved before the generation and behaviour of sonic booms are thoroughly understood. As far as the Concorde is concerned, the Royal Aircraft Establishment at Farnborough is confident that knowledge of the phenomenon, if not complete, is at least sufficient to allow Concorde flights to proceed. Unforeseen turbulence or topographic effects may perhaps cause prolongation or reverberation of the boom, but they are unlikely to affect the initial sound which is the main cause of annoyance. Unlike military aircraft, which can cause superbooms by abrupt turns or accelerations, the Concorde is expected to produce a superboom only at the period after take-off when its speed becomes supersonic. It is hoped that with suitable planning this superboom can be dumped in the sea.

Industrial Superconductivity

INTERNATIONAL Research and Development Ltd., a sponsored research organization based in Newcastle upon Tyne, announced this week that it has successfully designed and built an electric motor based on superconducting coils. This has been a dream of engineers since superconductivity—the phenomenon in which metals cooled to very low temperatures lose all electrical resistance—was first discovered by the Dutch physicist Kamerlingh Onnes in 1911. But it was not until the development of high-field superconductors and alloys capable of handling very large currents that it became clear that industrial development of superconductivity was worthwhile.



A 50 h.p. superconducting motor developed at International Research and Development Ltd. in Newcastle.

The project at IRD began as a feasibility study for the Ministry of Defence, and showed that a large superconducting motor was possible. Initially a small motor of only 2 h.p. was envisaged, but after some work it was realized that it would be possible to make a much more ambitious motor, producing 50 h.p. and running at 2,000 r.p.m. When this was built, further financial support was sought from the National Research Development Corporation, which appointed a working party to examine the proposal. Although the working party recommended that a 1,000 h.p. motor should first be constructed, NRDC decided to be bold and to go straight to a motor of 3,000 h.p. and 200 r.p.m., the size at which it is estimated superconducting motors will break even on cost with conventional motors. The large motor is to be tested at Fawley power station, by agreement with the Central Electricity Generating Board. The water cooling pumps at Fawley are rated at 3,250 h.p. and 200 r.p.m., designed to be driven by a conventional a.c. motor through reduction gearing. Although the conventional motor runs at 900 r.p.m. to produce the necessary power, the superconducting motor will be able to do it at 200 r.p.m. The stator for the Fawley motor will use a fully stabilized titanium/copper composite superconductor, cooled by a closed circuit helium refrigerator supplied by British Oxygen Cryoproducts Division. The rotor, which will not be superconducting, will be water cooled.

As well as using superconductivity, the engineers at Newcastle, led by Mr A. D. Appleton, have improved the design of the simple homopolar motor, first devised by Faraday. This type of motor, although very simple in design, has been slow to develop because it calls for a high current and low voltage supply. At IRD a system has been devised which uses a segmented disk —the rotor of the homopolar system—to overcome this difficulty, and Mr Appleton thinks that the new design may have potential uses in electric transport, though not in a superconducting form. Homopolar motors would have the distinct advantage that they could be used to regenerate the batteries while braking the vehicle.

The other advantage of the superconducting motor is a remarkable saving in weight. IRD estimates that with an 8,000 h.p. motor the saving in cost would be £70,000 (£150,000 instead of £220,000) and the superconducting version would weigh only one-ninth as much as the conventional motor. These advantages, IRD believes, will soon make the adoption of superconducting motors inevitable.

Cutting off Europe's Nose

TECHNOLOGICAL progress in Europe is being hampered by Britain's exclusion from the EEC. In an address to the Council of Europe on January 29, Mr Anthony Wedgwood Benn, Minister of Technology, reaffirmed the British Government's belief that technical collaboration "within an enlarged common market" is the only way Europe can hope to catch up and keep pace with the United States. Industrial and economic integration will be necessary for this, and European-based international companies must be created if industry is to operate on an adequate scale.

Despite the French veto, which "weakens European economic power in the face of transatlantic pressures", Britain is determined to pursue her policy of collaboration with the EEC and is prepared to consult with any country if mutual benefit will result. Mr Wedgwood Benn said that the decision to devalue the pound, which was taken in the hope of strengthening the economy, has turned Britain "decisively and irrevocably in the direction of Europe". Rationalization of industry within the country has been going on, notably in vehicle manufacturing and the electrical industries, and research projects are being examined for possible areas of collaboration with European countries. Computers, electronics and civil applications of atomic energy are three that have been mentioned already, but there are likely to be many more.

British collaboration is not, however, likely to be limited to Europe. Contact with the United States will be continued, and the technological agreements that have been signed with Poland, Hungary, Rumania and the Soviet Union will mean that planning techniques and long-term research will be discussed. Mr Wedgwood Benn stated his belief that "technological collaboration cannot come to full fruition except within the confines of a single industrial and trading market", and, although Britain's entry into the Common Market has been delayed, it is not too soon for a start to be made on collaboration in such fields as industrial standards, company law and patents which the Council of Europe has begun to examine. The European Institute of Technology proposed by the Prime Minister in November was described as an "organization that would provide an independent centre of analysis available to governments and industries on industrial structures, problems and future developments". It would provide a forum for technological exchanges, and by working in close collaboration with the EEC commission it could "play a major role in accelerating the achievement of a European technological community—a community which is essential if Europe's potentials are to be realized". But those who hoped that Mr Benn would finally disclose exactly what is in the Prime Minister's mind were disappointed. The European Institute of Technology remains a nebulous idea, splendid for injecting life into otherwise familiar speeches, but not apparently the subject of much serious study.

Unequal Trade

With the worsening of relations between rich and poor countries as a result of wars in the Middle East and in Vietnam and racial tension in many countries, the meeting of the United Nations Conference on Trade and Development (UNCTAD) which is taking place in New Delhi will not be all plain sailing. The last meeting in Geneva in 1964 was an acknowledged flop, and hopes for the New Delhi meeting are not high. Too many countries, Britain included, have gone to the meeting without a clear policy.

UNCTAD—defined in the most recent annual review of the Overseas Development Institute (ODI, 12*s*. 6*d*.) as "a forum for redressing the balance of the world's economic system in favour of the developing countries"—has not been a triumphant success in the past few years. Although one of its aims is to increase the production and value of commodities on which most developing countries rely, the price of commodities continues to fall. Increases in production or in productivity tend inevitably to be reflected by a decline in the prices paid for the commodities, so that the processes by which developed countries advance themselves tend to do the opposite for underdeveloped countries. UNCTAD also cherishes a hope of establishing aid to developing countries at the rate of 1 per cent of the GNP of developed countries, and of promoting tourism and regional co-operation between developing countries. But the chances of increasing aid at the moment are slim indeed—the British aid programme is to be fixed at the present ceiling of £205 million per year, despite devaluation, which means that the real value of the aid which Britain dispenses has fallen by between 8 and 11 per cent. This has happened after an actual cut of £20 million announced at the end of 1966, so that the value of British aid to developing countries has fallen steadily for the past two years. In the circumstances, it would perhaps have been unreasonable to expect anything else, but it is hard for developing countries to feel that Britain's economic difficulties, alarming as they are, are anything like as serious as their own.

The annual review from the ODI suggests ways in which developing countries can make the best of a bad situation. It would not be helpful, the report argues, if the developing countries use the present UNCTAD meeting to attempt to force concessions from developed countries. UNCTAD, the authors of the report say, must work through consensus—if the proceedings are based on bargaining from strength, it will be impossible to get the system changed for the simple reason that bargaining from strength has produced the very system which is under attack. The UNCTAD secretariat, headed by Dr Rául Prebish, has prepared a detailed analysis of the present situation, together with a series of proposals for action, but these have been treated with scepticism by some of the developed countries. The ODI report suggests that detailed argument about the way the case has been presented should not be allowed to obscure the basic issue—that the present system for operating world trade is biased against the developing countries. UNCTAD, the report concludes, must devote itself to changing the economic system, not to trying to secure concessions within the existing system.

Whether the developing countries accept this timely advice remains to be seen. There is little doubt, however, that without a new stimulus the world aid programme runs the risk of coming to a halt through political apathy in the developed countries. This is depressing, and in this context the occasional success stories are very refreshing. Pakistan and Kenya are likely to be quoted frequently at the UNCTAD meeting as examples of what can be done.

Reducing the Risks

The opening of the advanced Nuffield Transplantation Surgery Unit on January 31 by Sir Peter Medawar marks an important step forward in this extremely complex field. The Nuffield Foundation provided £230,000 towards the cost of the unit, which is at the Western General Hospital in Edinburgh.

According to Professor M. F. A. Woodruff, who is the director, the new unit has been designed for the treatment of patients who run a particular risk of infection because of having received immuno-suppressive agents. Three main categories of patients will be admitted; first, those patients receiving organ transplants and who are receiving immuno-suppressive drugs; second, patients with auto-immune diseases also receiving these drugs; and, third, certain types of cancer patients who have reduced resistance to infectious agents. The unit will, however, also be available to patients who have been accidentally exposed to radiation.

There are six patient rooms and two operating theatres in the unit. These work on a complicated system of ventilation with sterilized air under pressure which will prevent any cross-infection. All materials entering the unit will be sterile and wrapped, and communication between patients and visitors will be through glass and using microphones. The first patients will be those receiving kidney grafts.

Waiting, Not Yet Seeing

The meeting last week in Geneva of the Council of the European Molecular Biology Organization (EMBO) seems to have been a mixed success. The proposal for a central laboratory was presented by EMBO but not formally discussed—that will not happen until later this year. Nevertheless, a second firm offer of a site for the laboratory has now been made. As well as the offer of a site near Nice by the French Government last year, there is now the prospect of an Italian site near Rome.

At this stage, however, it seems that enthusiasm among some governments is more than counterbalanced by the scepticism of others. The West German Government, for example, seems to take the view that at this stage any attempt by EMBO to force the pace of a decision on the laboratory would invite refusal. Other governments, the British among them, take the line that the first step should be to make a decision about collaboration and continuing financing of the programme of fellowships and exchange visits on which EMBO has already embarked, chiefly with money from the Volkswagen Foundation. From this point of view, the laboratory is likely to become a live issue only towards the end of 1968, although there may be some discussion of it at the next governmental meeting arranged for April.

From EMBO's point of view, however, it is somewhat disconcerting that even the less ambitious set of proposals for fellowships and exchanges may not command full support by the next meeting. Although several delegations last week are known to have come out in favour of the fellowships, both the British and Belgian Governments—for different reasons—took a more negative line.

The British view seems to have been determined by recognition, rather late in the day, that even the proposal to finance EMBO fellowships on a continuing basis raises awkward issues of principle which have not yet been given the attention they deserve. There is, for example, the issue why molecular biology should be singled out for special treatment. There is also a fear that massive support for EMBO would serve unhealthily to institutionalize molecular biology. In more practical terms, although the amounts of money involved in financing the fellowships (as distinct from the laboratory) are comparatively small, it is inevitable, now that forward planning within a fixed budget has become everybody's watchword, that funds for EMBO will have to come out of somebody else's budget.

The difficulty here is that the Medical Research Council—one obvious source of finance—is likely to decide that it knows of better ways of spending its own money. At the same time, it is unlikely that the Royal Society would take kindly to a government instruction that a large part of the £200,000 a year which it has been allotted for European fellowships in all fields should in future be earmarked for EMBO. The result, in Britain, is most probably that the government will try to resolve its difficulties by a process of enquiry and consultation within the research councils and the Council for Scientific Policy. There may be some interest to see whether it can clear up its genuine difficulties without seeming to use consultation as a means of procrastination.

Franco-Soviet Space Agreement

SOME details have now been made available of the Franco-Soviet space agreement signed in Moscow on December 9. The agreement calls for the launching of a satellite containing an experiment of French design to make a spectroscopic analysis of the Moon's atmosphere, if it has one. The satellite will be launched at the end of this year or early in 1969.

Observations made during eclipses have given grounds for believing that the Moon may contain a thin atmosphere, produced, it is surmised, by volcanic eruption of gases or by radioactive decay of surface rocks, for example, of potassium into argon. Another possibility is that the high energy particles in solar winds might erode the lunar surface to the extent of releasing hydrogen and helium atoms; these might be retained by the Moon's gravitational field for brief periods. Any lunar atmosphere will probably be so tenuous that the exhaust gases from lunar landings could radically alter its composition; the experiment must therefore be performed as quickly as possible.

Another project outlined in the Franco-Soviet agreement is a study of the magnetic fields of the Moon. It has not yet been confirmed whether the USSR will make use of the French base at Kourou in Guyana for the launching of a manned satellite.

New Nature Reserve

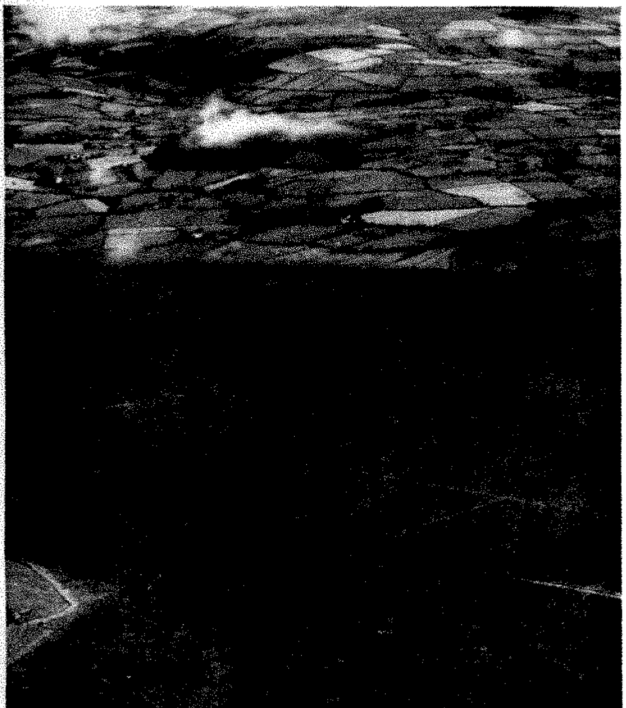
THE decision of the Natural Environment Research Council to establish a National Nature Reserve on about 182 acres of Cors Fochno, otherwise known as Borth Bog, in Cardiganshire, will be good news to many ecologists. There can now be no danger that draining will destroy a fine example of a relatively undisturbed raised bog.

Borth Bog is on the southern side of the estuary of the River Dovey and is an extensive area of acid peat which is in some places as much as twenty-three feet deep. The vegetation is very rich in mosses, and especially the genus *Sphagnum*—also known as bog moss. Among the species present is *Sphagnum imbricatum*, a peat-forming moss which is now quite rare in Britain. One of the problems now puzzling botanists is why this moss, which must have been the commonest when peat formation was progressing rapidly, has now become almost extinct.

Among the flowering plants there are no great rarities, but there are some interesting species. *Andromeda polifolia*, or bog rosemary, the pink flowered low woody plant, which is found on Borth Bog, is now decreasing on the bogs in the north and west of Britain. All three species of *Drosera*, the plant which catches insects on its sticky leaves, are found in close proximity at Borth, and this is a very rare occurrence. The fauna also has its interest; polecats, the stoat-like carnivores which are now rare except in central Wales, are numerous, and seventy-four species of butterflies and moths and twenty-two species of breeding birds have been identified.

As well as the distribution of the vegetation on the surface of the bog, and the effect on it of changes in the habitat, such as water movement, there is great interest in the history of the bog. Analysis of borings into the peat has revealed that the bog developed from fenland, later to be covered by forest, dominated by a sequence of different trees. The base of the bog is clay, containing Foraminifera—the fossil Protozoa which usually had a hard outer coat. Peat samples from 24 cm above the base of the bog contain less pollen from trees than from other plants, mainly monocotyledons, which suggests that this was fenland. The trees were elm, pine, oak and hazel. Samples from 34–54 cm above the base of the bog contain more pollen from trees than from other plants, with a marked preponderance of alder and birch pollen. The fen was evidently covered by forest, first dominated by alder, and later by birch. At 100–180 cm above the base the proportion of tree pollen decreases and there are many spores of the moss *Sphagnum*, and pollen of the small aromatic plant *Myrica gale*, also known as sweet gale or bog myrtle. The transition from fenwoods to raised bog—the peculiarity of a raised bog is that it has developed from the less acid fen—appears to be about 100 cm from the base of the profile.

This sequence resembles closely that found in the submerged forest which stretched intermittently between high and low tide marks for two miles along the coast between the villages of Borth and Ynyslas to the north. On the beach at Ynyslas there are exposed remains of tree trunks which were part of this forest.



Borth Bog, Cardiganshire, looking south-east. The Nature Reserve is shown in the middle distance. (Crown copyright; Dr J. K. S. St. Joseph.)

There is still much to be learnt about the historical aspect of Borth Bog. Dr Peter Moore of King's College, London, has recently made a series of borings in bogs, including Borth, and built up a historical picture of the human influence on the vegetation of central Wales. Pollen analysis can show, by such signs as the presence of a high proportion of weed pollen in peat samples, that man has been active in an area. There is other work in progress which is concerned with similar aspects of the history of Borth Bog, as well as various ecological studies on the surface, despite the impression given by the apparent paucity of published results. It will all be able to continue unhampered when the Nature Reserve is set up.

Documentation for Planning

HOUSING, building and planning are subjects which cut right across the conventional disciplines. As a result, the literature is diffuse and it is also inundated with trade material, good and bad, in enormous quantities. These problems make the proper organization of literature in the fields of housing, building and planning complicated, to say the least. There is not too much wrong with the two-way flow of information between North America and the countries of Western Europe, but it is a different story with Eastern Europe, Asia and Africa. There are the usual language difficulties, and most developing countries have far from sophisticated library and information services. It is hoped, however, that a new organization, an International Institute for Documentation of Housing, Building and Planning, will help. A talk about this was given recently at Aslib headquarters by Mr Agard Evans, former Chief Librarian, Ministry of Public Building and Works.

There are already in existence several organizations concerned with building and planning on an international scale—the International Council for Building Research, Studies and Documentation (CIB), and the International Federation for Housing and Planning, for example. None of the international bodies, however, appears to have the terms of reference, the funds or the facilities to cover documentation in building and planning on a world-wide scale. This is why it is proposed to set up a new institute which would be able to channel all its energies and resources into the problems of documentation. The Economic and Social Council of the United Nations has had the institute in mind for some time. Before giving final approval to the project, the council asked that an expert group of four from India, Czechoslovakia, France and Britain should undertake a feasibility study. The group, of which Mr Evans was the British member, met twice last summer and presented a unanimous report to the council in September. A draft resolution was approved and this is to be put before the full council meeting in May this year.

In outline, the proposal is to establish the headquarters of the institute in New Delhi. This will be supported by national documentation centres in each member country. Staff in New Delhi, documentalists, translators and others, will disseminate information on housing, building and planning in various ways—through "digests" (extended summaries of a selected number of primary documents, 100 per month); annotated references; abstracts (selected from those already published in the field); and "syntheses" (reviews of the subjects from primary and secondary sources). These services would be in four languages—English, French, Russian and Spanish. The national centres would assist in all this by making the information available to practitioners in their country. The institute in New Delhi would also act as an information centre for queries which cannot be answered from existing national sources. If necessary, queries could be channelled to the other international centres. Secondary functions of the institute could include standardization, classification and giving advice on any aspect of documentation in the fields covered. But it would not undertake full-length translations, critical appraisals of literature, the publishing of textbooks and manuals, nor anything falling outside the boundaries of documentation.

There is now a working party busy with all the details. If approved, the new institute should be fully operational within about 15 months. There remain some big questions. The institute will have to rely on voluntary support from governments. Will enough money be found for the capital costs and running expenses? The Indian Government is helping with staff and buildings. Are other countries going to follow? How will the institute select material? How will it be staffed? Documentalists are already hard to find.

Welsh Primary Schools

All primary schools in Wales should eventually become bilingual. With this aim as the chief recommendation in its newly published report, the Central Advisory Council for Education (Wales) must have gone a long way towards satisfying the Welsh Nationalists. The second recommendation, more the concern of educationists, calls for increased attention to in-service training and advisory services for teachers. One week's study leave on full pay for each year of service is recommended for all teachers.

A considerable amount of reorganization in rural areas is called for, so that the smallest schools will have a minimum of 50–60 pupils and not less than three teachers. Area schools in key villages are suggested for such areas, with the limit of 45 minutes being placed on the travelling time of the children. The committee comes out in favour of all-through schools for 5 to 12 year olds, rather than a two-tier system with a move at the age of 8. It is hoped that the schools can be connected with community centres dealing with social and welfare services and those which provide for leisure and further education. Liaison between these different groups in community life should be encouraged and teachers could help in this respect, particularly if, during their training, more emphasis is placed on this aspect of their work. The pattern of teacher training courses was given some attention, but the council believes that a full enquiry into the system is necessary.

The council was set up in April 1964, under the chairmanship of Professor C. E. Gittins, Professor of Education at University College, Swansea. This was some months after the English equivalent, under Lady Plowden, but the terms of reference given to both bodies "to consider primary education in all its aspects and the transition to secondary education" were identical. Professor Gittins and Miss S. E. Grey, Organizer for Infant Education for Glamorgan, served on both councils, and thus maintained close contact between the two groups. In general, the recommendations of the Gittins Report agree with those put forward by the Plowden Council, but additions are made wherever matters of special concern to Wales are mentioned.

Religious education was investigated by the council, and it was suggested that compulsory religious instruction be left to the discretion of head teachers. Professor H. D. Lewis, Professor of History and Philosophy of Religion at King's College, London, did not agree with the recommendations of the council. He believes that religious education should be compulsory, and did not sign the report. Professor D. C. Marsh, Professor of Applied Social Science at the University of Nottingham, did not support the recommendations for a fully bilingual primary education in Wales.

Action of Drugs

Professor M. J. H. Smith is the director of a new research department of biochemical pharmacology which has been instituted at King's College Hospital Medical School, Denmark Hill. The department, which consists of 2,000 sq. ft. of laboratory space, was made possible by a grant of £24,000 from the Nuffield Foundation and a subsequent grant from the University of London.

The research work in the new department will attempt to gain an understanding of the way in which drugs affect normal and diseased people; in particular the effects of anti-inflammatory drugs such as aspirin, phenylbutazone, indomethacin and various steroids used to treat rheumatism will be studied. This will involve investigating their effects on metabolic processes and tissue enzymes and using the results to explain known clinical and toxic effects of the drugs.

The cost of equipment, which includes a computer, radioactive counting material and a refrigerated respirometer, is being met by part of the £9,000 grant from the University of London, and also by a grant from King's College Hospital and Medical School Joint Research Committee. In addition, the Nuffield Foundation has made a three-year grant of £11,537 which includes a fellowship, and the Arthritis and Rheumatism Council is allocating £32,000 over the next five years.

Value from Scrap

Anything to reduce the British import bill is welcome these days, so that the work of the Warren Spring Laboratory at Stevenage in the recovery of valuable metals from scrap residues and waste is likely to be enthusiastically taken up. This particular research, which uses chemical processing techniques, is helpful to the non-ferrous metallurgical industry which depends heavily on imported raw materials. New techniques are also being developed for the extraction of rarer metals needed for high-duty alloys and for electronic devices, and for the finer purification of primary metals. The mineral industry is also likely to benefit from the new methods of dry separation of minerals which are being developed. Two separators using air fluidization which could be used in regions of the world where water, the normal medium, is scarce, are described in the laboratory's annual report for 1966, just published (HMSO, 8*s*. 6*d*.). Work in the mineral processing field accounted for some 40 per cent of the total expenditure of the laboratory.

An important 35 per cent of the expenditure was spent in the chemical engineering division. Some of the most significant experiments being done are those on the computer control of complex chemical processes. A pilot plant which produces acetone by the dehydrogenation of iso-propanol is being used to examine different forms of digital control. The computer used is an ARCH 9000. During the past year, the instruments and computer systems of the plant have been modified and extended in various ways. It is only by re-designing the plant and processes that the full possibilities of computer control can be gauged. Short specialized training courses for chemical engineers from industry are being held at the laboratory so that detailed knowledge of the methods and techniques of process control may be diffused through the process industries. A second project to study computer control has now been started. This is a study of the control by computer of a fast chemical reaction (oxidation of hydrocarbons) in a transfer-line reactor, in which effective control to obtain conditions of maximum conversion can be done only by computer. The work so far has been mainly on computer control of large-scale and complex continuous processes. The laboratory has found, however, that there could also be improved control of a number of processes on a smaller scale. Research has been started, therefore, on control of batch distillation with an assembly of digital logic and analogue elements.

Several other investigations are described in the report. These include work on viscometers and flowmeters, and the development of an on-line particle size sensor and a new fluorine analyser based on neutron activation. The work on flow properties, mixing storage and bulk-handling of granular materials has led to designs for mass-flow hoppers. These have been successfully applied in a number of different industries.

It has been estimated recently that air pollution costs Britain £350 million annually, quite apart from any losses caused by its effect on health. The laboratory spends just over 20 per cent of its total expenditure on research in this field. In 1966, increased attention was paid to pollution arising from vehicular traffic and to the reactions of pollutants in the atmosphere.

Coexistence in Botany

Since the merger in September 1967 of the Departments of Botany and Agricultural Botany at the University College of North Wales, Bangor, a noteworthy effort has been made to break down the barrier between pure and applied plant sciences.

The School of Plant Biology—as it is now called—was instigated by Professor P. W. Richards with the aim of covering the widest possible range of botanical subjects and with the intention of ending the separation between pure and applied disciplines. According to Professor J. L. Harper, who is head of the new school, the union has brought in an academic staff of twenty-three, and a number of building alterations have made it possible to house almost all the academic staff in one main building. Teaching and some research activities are, however, still spread over a number of buildings.

The school now possesses two field stations. One of these is the 28 acre research station of the School of Agriculture at Pen-y-ffridd; it has research laboratories, and controlled environment facilities are provided. The other station—Treborth botanic garden—is approximately the same size and has laboratories, woodland and an experimental garden. The greater part of the work in systematics is concentrated at Treborth, and physiology and experimental ecology are developed at Pen-y-ffridd.

Within the school there are now two M.Sc. courses—one in pure and applied ecology and a second in crop protection. The latter with an intake of about ten graduates a year is particularly valuable, according to Professor Harper, for strengthening the links with agricultural industry.

Undergraduates are, however, the main interest in the school, which still offers degrees in agricultural botany and botany. Students are offered an extremely wide range of choices in the honours degree option, so that a student can specialize in an aspect of the plant sciences covering both pure and applied science disciplines. The merger has also produced a very large research group and there are at present thirty-four students working for postgraduate degrees—a healthy number for any university department. Part of the finance is provided by the Science Research Council, part by the Natural Environment Research Council, and the Ministry of Agriculture provides studentship awards. But in addition there are a number of students engaged in work supported by industry, and there are also students supported by the Copper Development Association, the Zinc Development Association and the International Copper and Zinc Research Association.

Parliament in Britain

Agriculture

Mrs Shirley Williams, Minister of State, Department of Education and Science, stated that in the United Kingdom in 1966, 431 students qualified for university first degrees in agricultural subjects and 194 for higher degrees or diplomas. In 1967, 482 qualified for diplomas, 1,799 for certificates following full-time courses and about 13,000 for certificates in individual subjects following part-time or block release courses in further education. (Written answer, January 25.)

Power

The Parliamentary Secretary to the Ministry of Power, Mr R. Freeson, stated that the inclusion of the allowance for the effect of devaluation changed the estimate of the cost of electricity from Dungeness *B* nuclear power station from 0·56*d.* to 0·57*d.*/kWh. The effect on the operating costs at Hunterston *A* station was likely to be marginal and at Hunterston *B* was unlikely to be significant, although depending largely on the final terms of individual contracts. The total consumption of fuel oil at power stations in the United Kingdom was estimated at 7·3 million tons in 1966 and 7·4 million tons in 1967. Mr R. Marsh, Minister of Power, stated that the Central Electricity Generating Board estimated the construction cost of Hinkley Point *B* at £71/kW and the base load generating cost, including capital charges, at 0·52*d.*/kWh. For Drax, the most advanced coal-fired thermal power station offered to the board, the corresponding figures are £52/kW and 0·60*d.*/kWh. He was advised by the board that with pithead coal prices of 3*d.*, 4*d.*, 5*d.* and 6*d.* per therm, the estimated base load generation cost per kWh of the most advanced coal-fired power station would be 0·55*d.*, 0·65*d.*, 0·74*d.* and 0·83*d.*, respectively. (Written answers, January 19, 22 and 23.)

What French Scientists Do

THE results of a detailed survey of the origins and the employment of research scientists in the French public service, including higher education, have now been published by the Délégation Générale à la Recherche Scientifique et Technique (*Les Chercheurs du Secteur Public en Sciences Exactes et Naturelles*). Because the public sector employs close on 60 per cent of the 50,000 or so research workers thought to be active in France at present, the census is likely to be a reasonably accurate picture of the management of scientific resources in France. The analysis now published is based on detailed replies collected during 1963–65 from 11,000 scientists working either in the French civil service or in higher education.

Physicists account for 31 per cent of the research workers covered by the survey. Biologists account for 29 per cent, chemists for 25 per cent, mathematicians for 8 per cent and geophysicists of various kinds for the remaining 7 per cent of this population of research workers. The survey did not cover people working in medicine and related disciplines or in the social sciences. One striking feature of the results is the comparatively high proportion of women at work in French laboratories, particularly in biology. For the public sector as a whole, roughly 20 per cent of the research workers are women; the proportion varies from 11 per cent in physics to 28 per cent in biology. The report points out that in the United States the proportion of women research workers in the public sector is only 9 per cent.

As elsewhere, the population of research workers in France is comparatively young. For the public sector as a whole, the median age of active research workers works out at 35 years. Chemists and physicists tend to be younger than biologists—a third of active chemists are in their twenties compared with a fifth of biologists. Although the report raises questions about the likelihood that a person's productivity and creativity may be determined by his age, the chances are that these small differences are consequences of the different rates of growth of different disciplines.

The French labour force includes a surprisingly high proportion of people from abroad. For the public sector as a whole, it seems that 4 per cent of active research workers are from countries outside France, roughly half of them from elsewhere in Europe. For the labour force as a whole, 45 per cent of research workers are to be found in higher education and roughly a quarter of them work directly for the CNRS. There are, however, sharp differences between the distribution of people with different kinds of qualifications. The Atomic Energy Commission (CEA), for example, employs more than a quarter of all physicists, nearly two thirds of mathematicians are to be found in universities.

Of those engaged in research in France, the majority seem to be trained at French universities. The Grandes Ecoles and the similar institutions in France provide a great many qualified people in science and technology, but many of these finish up in the private sector. The result is that 53 per cent of active research workers are trained in universities, just over a third in the Grandes Ecoles and 2 per cent at institutions outside France. One interesting feature of the statistics which have been collected is that 6 per cent of those active in research appear to have had their training at Ecoles Normales Supérieures, chiefly at a handful of particularly distinguished institutions of this type. Most of the women who make a career of research seem to have a university background. The same statistics show how comparatively small a proportion of French scientists include in their training a spell abroad.

The statistics also illustrate how French scientists tend to acquire higher degrees at a comparatively advanced age. Of those active in research, 27 per cent had qualified as doctors of science, but at a median age of 42 years. The more recently introduced doctorate based on a programme of study and research at a university immediately after baccalauréat seems to be held by roughly 6 per cent of the population of active researchers but, even there, half of the scientists concerned seem to have had to wait until they were 30 before qualifying. If anything, the age of qualifying seems to have increased over the past four decades.

In the public sector as a whole, teaching seems to account for a substantial proportion of the time and energy of qualified scientists. Altogether, 18 per cent of a person's time was spent on teaching, compared with 60 per cent on research. Mathematicians as a whole are the most diligent teachers (25 per cent of everybody's time), physicists get off most lightly, with an average of 12 per cent of time spent on teaching and 63 per cent on research. Understandably, the proportion of time spent teaching is greatest among those employed in universities—just over 33 per cent compared with 41 per cent for research. In the universities, it seems to be the rule that the most junior people do the most teaching. Assistants—the lowest grade—can expect to spend 38 per cent of their time teaching and 43 per cent of it on research. By contrast, professors spent 24 per cent of their time teaching and just as much on research. The report does not define accurately what it means by teaching, but in comparison with university people elsewhere, those in France probably carry the heaviest burdens.

The survey of French research workers has set out to discover how well equipped they are to deal with scientific literature from abroad. According to the information which has been collected, 7 per cent of active research workers confess to having no knowledge of a foreign language, but the Délégation Générale is quick to point out that the corresponding proportion in the United States is 27 per cent. In France, mathematicians seem to be the least well equipped with foreign languages—13 per cent of them know no foreign language compared with only 3 per cent of chemists in a similar state of ignorance. Most scientists in France, apparently, know at least two foreign languages and among the languages quoted English was at the top of the list (83 per cent) and German next (42 per cent). Of the scientists included in the survey, 14 per cent seem to have spent some period abroad on scientific business, with doctors of science among the most widely travelled. In the physical sciences the United States seems to be the favourite visiting place (with roughly half of those included in the survey). Among geophysicists and biologists, Africa claims pride of place.

NEWS AND VIEWS

Problems of European Integration

It is, of course, disappointing that the meeting in Geneva last week about the continued financing of the activities of the European Molecular Biology Organization should have made so little progress (see page 401) This is particularly ironical at a time when the foreign ministers of several European countries, meeting in Brussels, were congratulating themselves on their willingness to collaborate in all kinds of schemes for the integration of European institutions and interests

At the same time, it is only proper to acknowledge that the proposals which EMBO has put forward raise important issues of principle To be sure, it is hard to see why these have arisen so late in the day It is also hard to see why the example of CERN does not serve, to scientists as well as to administrators, as a proof that putting money into EMBO would not be the same as pouring it down the drain If there is to be further discussion about the proposals, it is to be hoped that it will be at once public and quick It is a great misfortune that the British Government, now apparently embarking on another process of enquiry into the rightness or wrongness of the scheme, should not have done the job more thoroughly at the beginning, perhaps a year or more ago

That said, it is important not to overlook the developments which have already taken place towards the integration of scientific institutions in Western Europe The way in which several national academies in Europe are collaborating—with funds provided by their governments—on the exchange of fellows and students from one laboratory to another is a splendid development with great promise for the future In this connexion, the part which has been played in the past by the North Atlantic Treaty Organization should not be overlooked The organization has been particularly influential in supporting summer schools for senior postgraduate students and the like at dozens of centres in Europe on an increasing scale One way and another, several of these summer schools have already grown into more or less permanent and regular institutions The only trouble, of course, is to know at this stage what is to happen to activities like these, financed through NATO, when the treaty is revised in 1969

If all these schemes for increasing the cohesion of the profession of science in Western Europe are put together, however, it must be acknowledged that they do not by any means match the real need for closer integration and real exchange between laboratories and universities Moreover, it is hard to see how the existing machinery could adequately administer the very much larger sums of money that would be needed if travel between one place and another in Western Europe were to become as free as it should be for scientists and technologists

In the past few years there has also been welcome progress towards the federation of learned societies in several disciplines Biochemical societies, for example, have created not merely a common institution but a journal of their own as well The physical societies are at present in the thick of negotiating a constitution for a federal organization, and will probably be able to launch this officially in the autumn It remains to be seen how far they will be able to go in the rationalization of journals, the development of international conferences and the administration of exchanges between laboratories, but at present everybody seems to be hoping for the best But even here, unfortunately, a few swallows do not make a summer It is unthinkable that the integration of European science should be allowed to proceed by the independent decisions of academies of different disciplines to link themselves together

This is why governments should be much more ready to take a hand than they apparently were last week at Geneva The long-term need is for the creation of institutions on a European basis which can help somehow to administer policies as well as charitable donations Professor Waddington made a strong case, in his contribution to the new OECD report on science policy in the United States, for a sharing of decision-making within Western Europe on new projects of research What he had in mind was the inclusion in the national research councils such as the Science Research Council of council members from other European countries The virtues of this development would be not merely the avoidance of overlap between research projects undertaken in different countries but the creation of means for the improvement of the proposals put forward by teams of scientists in separate countries This, as it happens, is a modest version of the kind of proposal which ought now to be considered seriously in Western Europe

Applying Holography

The progress that is being made in holography was reviewed by Professor D Gabor and nine others in a symposium held during January 17–18 at the National Physical Laboratory The meeting was organized by the Optical Group of the Institute of Physics and the Physical Society in conjunction with the Stress Analysis and Materials and Testing Groups The audience numbered more than 300 for each of the three sessions

In his opening paper Professor Gabor drew attention to some of the ways in which holography could be used to fabricate unusual types of optical element If recording materials of improved phase-recording quality could be found, then several uses could be foreseen for composite reflectors containing a very large number of stacked Lippman reflecting layers. He referred also to the increasing American interest in acoustic holography, which could be an attractive alternative to X-rays in medical diagnosis.

Of the papers that followed, two dealt with ultrasonics and with the problems of recording particle tracks in a bubble chamber, and three were concerned with fundamental optical aspects of holography. The paper by J. W. C. Gates (NPL) emphasized the advantages of pulsed laser holography and included a live demonstration in which a hologram was handed round the audience only minutes after it had been recorded on the platform.

The remaining papers dealt with measuring applications and made it clear that, although holography as a means of processing information has been studied for many years, its more recent role as a measuring tool is at least equally important.

The paper by A. E. Ennos (NPL) reviewed some of the ways in which hologram interferometry can be used to measure either minute changes in the shape of an engineering component or departures from a holographically recorded master shape. The highlight of this presentation was a short cine film which demonstrated the advantage of a new stroboscopic method, as opposed to the time averaged technique, for studying the vibrations of an acoustic resonator the resonances of which are sharp. J. M. Burch (NPL) described a new holographic version of the "moiré shadow" test which should make it possible to test a diffusely reflecting component such as a turbine blade with a reduced sensitivity of perhaps 400 fringes per centimetre of error. W. R. B. Bradford (EMI) illustrated the experimental precautions that are needed for holographic metrology, and showed results that should be of forensic as well as of engineering interest. It appears, for example, that if a floorboard is dented, Dr Bradford can determine which if any of the dents is less than an hour old.

The brief symposium was accompanied by several holographic demonstrations which were arranged by the NPL Division of Optical Metrology in an adjoining laboratory. A high degree of interest was shown throughout, and this augurs well for a full international conference on "Engineering Uses of Holography" which is to be held at the University of Strathclyde between September 17 and 20.

Extraction by Bacteria

from our Microbiology Correspondent

FOURTEEN years ago it was found that certain sulphur-oxidizing bacteria could accelerate the extraction of copper sulphide ores. Considerable use is now made of this leaching process which has rapidly attained importance as the necessity to exploit low-grade ores has arisen. This extraction process has been studied both in the laboratory and the field, and reports in the current number of *Biotechnology and Bioengineering* indicate the present state of our knowledge and the problems involved in optimizing the conditions for a successful commercial operation. Beck (*Biotech. Bioeng.*, IX, 487, 1967) has surveyed the practice of copper leaching in several mines in the western United States and, although the control of the process and the extent of the recovery varied greatly, essentially the same procedure was employed at all mines. Where convenient, the waste or low-grade ore (up to 20 million tons) is deposited in a ravine which forms a natural collection system and water is percolated through the ore dump. Pregnant waters rich in soluble copper and ferric iron feed a collection pond and then are piped to a precipitation plant where the copper is recovered and the iron is in part reduced to ferrous sulphate. Spent waters are subjected to further microbiological action in an oxidation pond in which iron is precipitated as hydrated ferric sulphate with a concomitant decrease in acidity. Finally, the spent waters are recycled through the ore dump and sulphuric acid added *en route* to maintain optimal *p*H conditions. Beck's survey proved a consistent association of *Thiobacillus ferrooxidans* with leaching waters and exposed ores and a massive development of this bacterium in the oxidation ponds. Stimulation of thiobacilli in this latter site provides a large inoculum in the percolate and removes much of the iron which might precipitate and cement in the upper layer of the dump and thereby impede percolation. As the water passes through the packed ore the viable thiobacilli decrease in number, an observation which could be taken as inconsistent with their proposed activity on sulphide ores. The massive dimensions of the leaching system, however, are likely to impose absorption and filtering out of bacteria and produce stratification and localized accumulations of organisms. In turn, localized heating, up to 80°, would have a two-fold effect—a decrease in the bacterial population, and a possible enhancement of chemical oxidation at the expense of microbiological activity.

The exact contributions which bacteria make to copper leaching are not known fully, but the efficacy of their activity is determined by a complex interaction of physical, chemical and biological factors. Ehrlich and Fox (*Biotech. Bioeng.*, IX, 471, 1967) ascribe three major functions to the thiobacilli: (1) direct oxidation of the sulphide ores, (2) regeneration of ferric iron which becomes involved in chemical oxidation of the ores, and (3) depressing the release of iron from the ores. Although it is possible only to assess the combined contributions made by thiobacilli at present, Ehrlich and Fox have studied parameters such as the nature of the gangue and mineralogy of the ore, particle size, the availability of oxygen and carbon dioxide, the *p*H, E_h and temperature, and the nutritional status of the system. This last point may affect the growth of heterotrophic micro-organisms, and either promote or inhibit the extraction process, by, for example, acid and sulphide production respectively. Unfortunately the scaling up of laboratory findings to field situations has had only limited success so far, and it is clear that more thorough evaluation of the *in situ* process along the lines of Beck's survey is a very necessary adjunct to simulated experiments in the laboratory.

The Wake of the Moon

from our Magnetosphere Correspondent

IN July 1967, the National Aeronautics and Space Administration in the United States succeeded in injecting the satellite Explorer 35 of the IMP series into orbit around the Moon. The instruments included two magnetometers and a plasma probe, and the preliminary results from one of the magnetometers (Colburn *et al.*, *Science*, **158**, 1967) tell an interesting story which suggests that when there has been time for the data from one of the magnetometers and the plasma probe to be put together, progress will be made with a basic plasma problem. This kind of data analysis necessarily requires a considerable time, however, and the data from each instrument are first studied separately. It may be noted that the Russian lunar orbiter Lunik also carried a magnetometer, but the measurements (Zhuzgov *et al.*, *Cosmic Investigations*, **4**, 880, 1966) showed a magnetic field strength an order of magnitude stronger than that found by Explorer 35. Since it is much easier to imagine causes of error leading to spuriously large fields than to spuriously low fields, it is most probable that the Lunik measurements are erroneous. It may also be noted that some check on the Explorer 35 measurements can be obtained by comparison with Explorer 33. This was launched a year earlier, was intended to orbit the Moon, but went into an Earth orbit with apogee farther than the Moon and is still operating. Furthermore, Explorer 35 is spin-stabilized along an axis nearly perpendicular to the ecliptic and any spacecraft field perpendicular to this axis is corrected for. The altitude of periselene is about one half of a lunar radius and that of aposelene about 4.5 lunar radii.

One remarkable negative discovery is the lack of a bow shock in front of the Moon. This would have appeared as a rather sudden increase in field strength and onset of turbulence as the satellite crossed the shock from upstream. The Earth's bow shock is clearly seen in the variance of the magnetic measurements on Imp 1 (Ness *et al.*, *J. Geophysical Res.*, **69**, 3531, 1964) in a distance quite small enough compared with the size of the Moon. The absence of a bow shock implies that the Moon does not appreciably disturb the flow of the Solar Wind. An early speculation (Gold, in *The Solar Wind*, Pergamon Press, 1966) suggested that the Solar Wind protons would be neutralized at the lunar surface but that an electromagnetic interaction would be found if the whole Moon had an electrical conductivity comparable to that of the Earth's crust. Briefly, in the Solar Wind the electric field is zero in the frame of the plasma and hence non-zero in the frame of the Moon, unless the magnetic field is parallel to the wind—an unusual situation. Such an electric field would drive a current through a conducting Moon in a direction which would increase the magnetic field on the upstream side; if this increase were appreciable, a shock should occur. It can be concluded that at least the outer layer of the Moon is a good insulator; by studying the time-variable fields near the Moon, electromagnetic sounding of the internal conductivity should be possible and hence some indication of internal temperature.

The other discovery by Explorer 35 is an enhancement of magnetic field strength downstream of the Moon which is plausibly interpreted as the result of a plasma void where the wind has been intercepted by the Moon. This is best understood hydromagnetically as an increase of magnetic pressure in the void caused by the lateral pressure of the plasma outside. The increase of the field propagates inward at the Alfvén speed in the void (assumed to be less than the speed of light) while the plasma closes in at about its thermal speed. The shape of the void should be mapped out as the aposelene of the lunar satellite swings round on the dark side. The structure of the plasma front moving into the void is a basic plasma problem of great interest, previously inaccessible to detailed measurement. The enhancement of the field in the void is not particularly reproducible, but this is probably accounted for by variations in the interplanetary field. Still less reproducible, but usually present, are large but short-lived decreases of field strength on either side of the void. Hydromagnetically this implies an increase in lateral pressure in the plasma which has just missed the Moon. This is plausible but not properly understood, and again suggests that the combination of the data from the plasma probe and the magnetometer will be fruitful.

Sequences and Structures

from our Molecular Biology Correspondent

ONE of the most far-reaching technical advances in the nucleic acid field in recent years has been the development by Sanger of procedures for separating and identifying radioactively labelled oligonucleotides. This culminated in a determination of the complete sequence of an RNA of 120 residues, containing no "unusual" bases, such as could be used as markers in the sequencing of transfer RNA species. The subject of this *tour de force* was the 5*S* RNA associated with the ribosomes of *E. coli*. Similar 5*S* species are present in other ribosomes, but their function remains obscure. The sequence of one of them, from mammalian ribosomes, has now been reported by Forget and Weissman (*Science*, **158**, 1695, 1967).

This RNA, isolated from KB carcinoma cell ribosomes, has 120 residues, and has other features in common with its bacterial counterpart; the 3′-terminus is uridine in both cases, but the KB cell RNA has guanylic acid, rather than uridylic acid, at the 5′-end. The sequence presents the possibility of fairly extensive base-pairing, and in particular complementary sequences of nine nucleotides occur at the two ends of the chain (residues 1 to 9 complementary with 118 to 110), so that these must be presumed to be united in a double-helical segment. In *E. coli* 5*S* RNA there are sets of ten complementary bases at the ends, but in both molecules isolated G-U pairs occur in these sequences. Other sets of complementary sequences, including one of nine residues, are found. As in the bacterial RNA, there is a run of five residues which is complementary to a four- or five-base sequence common to all transfer RNAs so far determined. This then reinforces speculation about a site for the attachment of *t*RNA to the ribosome.

The emergence of the primary structures of the various 5*S* and transfer RNAs has naturally provoked a fever of activity in a number of quarters. Most of all, it has stimulated attempts to work out the secondary, and even the tertiary, structure of these molecules solely by contemplation of the sequences. In favour of this agreeable pursuit, it must be said that the "cloverleaf" model for *t*RNA, which was deduced by comparing the several known sequences, remains an unchallenged working hypothesis, at least in respect of the pattern of base-pairing. The first serious attempt to establish experimentally how it relates to the overall appearance of the molecule comes now from Lake and Beeman (*J. Mol Biol*, **31**, 115, 1968) They have measured X-ray scattering at low angles from yeast transfer RNA in aqueous solution The scattering profile depends on the distribution of matter within the solute molecule, and it is possible to calculate the scattering for given models for the tertiary structure with considerable precision. Starting from a "cloverleaf" arrangement, containing four paired segments, Lake and Beeman are able to assert that the limbs are not splayed out, the *t*RNA is in fact a compact and disymmetric structure, and a good fit between experiment and theory can be achieved if the arms are packed tightly together The best fit is for a two up – two down configuration, but three up and one down is not excluded Granted the original "cloverleaf", therefore, this work must be seen as a considerable step towards a picture of the molecule

No such working model exists as yet for the 5*S* RNA An attempt at characterizing the secondary structure has been made by Boedtker and Kelling (*Biochem Biophys Res Commun*, **29**, 758, 1967) They have shown the existence of a considerable degree of base-pairing by demonstrating that the structure collapses when treated with formaldehyde The absence of any significant ionic strength dependence of the sedimentation coefficient indicates that there is in fact a rigid tertiary structure Measurements of ultraviolet hypochromicity in the native state, by comparison with that in the formaldehyde-treated material, have been used to obtain a limiting value for the extent of base-pairing For reasonable values of mean hypochromicity for paired and unpaired RNA chains, it is found that some 60 per cent or more of the bases are paired

Zonal Centrifugation

from a Correspondent

MORE than 200 people attended the British Biophysical Society meeting on zonal centrifugation on January 26, organized by Professor P Alexander at the Chester Beatty Research Institute Laboratories at Sutton Professor D E Hughes in his opening remarks described the development of the zonal centrifuge as a major breakthrough in the separation of biological material One of the major fields of study in contemporary biological science is the relationship between function and structure In order to study this it is necessary to obtain sub-cellular components in as pure a state as possible The old method of differential centrifugation produced very impure fractions, while the introduction of separation by density gradient centrifugation in swinging bucket rotors improved the quality of the fraction at the cost of greatly reduced yield With zonal centrifugation using rotors with capacities of up to 1,700 ml, it is possible to obtain fractions in quantities sufficient for almost any analytical procedure

Dr N Anderson of Oak Ridge who, with his co-workers, has been responsible for the development of the zonal centrifuge, started the proceedings with a major contribution entitled "Recent Advances in Zonal Centrifugation" This paper, lasting nearly an hour, was delivered with expertise and humour He described a number of interesting modifications in technique which can be applied to zonal centrifugation and which considerably extend its potential Among the successful applications so far is the production of highly purified viral vaccines using a flow-through rotor to process 1 to 2 litres per hour of culture medium One of the latest developments at Oak Ridge is a new generation of rotors, the "*K*" series, capable of handling four or five times the quantities of the present "*B*" series

The following papers were each concerned with the isolation of one or more components from disintegrates of biological material The overall impression was that the workers had achieved a degree of resolution and reproducibility not obtainable with any other method Dr J Hastings (Chester Beatty Research Institute) described the separation of different species of RNA using the *B* XV titanium rotor

Dr C. D Birnie and Dr Harvey (Imperial Cancer Research Fund) then showed some excellent separations of polysomes, ribosomes and ribosomal sub-units In the afternoon session, together with Miss S M Fox, these authors also described the use of the continuous flow rotor for the isolation of viruses

During the luncheon break, demonstrations of *A*, *B* XIV and *B* XV rotor systems were given by MSE of Crawley, England The afternoon session was opened by Dr R G Wallis (Microbiological Research Establishment), who described a simple containment device for use in conjunction with the zonal centrifuge for the isolation of non-pathogenic viruses

The complex problem of the isolation of cytomembrane and plasma membrane fragments from liver homogenates was dealt with by Dr E Reid, Mr R H Hinton and Mr J T R Fitzsimons (University of Surrey), and this was followed by a paper on "The Separation of Mitochondria and Lysosomes" by Mr G C Hartman and Mr R H Hinton.

Dr D Lloyd (University College of South Wales and Monmouthshire), using the *A* rotor, showed that the zonal centrifugation of a fraction rich in mitochondria resulted in the mitochondria separating into fractions having different metabolic properties but appearing as a broad band on the zonal profile Dr A P Mathias (University College, London) showed what degree of separation of nuclei could be achieved using the *A* rotor Using low speeds of the order of 600 r p m, he had separated diploid and tetraploid nuclei from rat liver

The final paper by P J G Avis, Dr C Dean, Dr A Driedger and Dr L Hamilton (Chester Beatty Research Institute) dealt with the separation of disintegrates of *Micrococcus radiodurans* using the *B* IV rotor A novel feature was the lysing of the bacterial cells within the rotor to avoid excessive shearing of the DNA during the introduction of the sample through the rotating seal

This was the first meeting to be held in this country devoted entirely to the technique of zonal centrifugation and drew one of the highest attendances for a meeting organized by the society

Lactose Repressor

from our Cell Biology Correspondent

THE isolation at Harvard University of the lactose operon and λ-phage repressors by Gilbert and Muller-Hill and Ptashne has made possible fundamental experiments to detect how genetic repressors act at the molecular level Last year, Ptashne (*Nature*, **214**, 232, 1967) showed that the λ-phage repressor binds specifically to the operator region of the λ-DNA molecule. This result supports the simplest model of repression—namely, that the repressor protein itself binds to DNA and that this binding somehow prevents transcription of the subsequent genes into *m*RNA In the current issue of *Proc US Nat Acad Sci*, (**58**, 2415; 1967), Gilbert and Muller-Hill report that the lactose repressor binds to the operator region of lactose operon DNA molecules and, furthermore, that the repressor molecules are released from the complex with DNA by inducers.

To do the experiments, Gilbert and Muller-Hill labelled *E coli* with radioactive sulphur and then isolated from the cells protein sedimenting at 7–8*S*, which includes the repressor. About 1 per cent of this labelled protein binds to DNA isolated from a defective λ-phage which carries the *E coli lac* operon in place of part of the λ-genome Moreover, a synthetic inducer of the lactose operon, isopropyl-1-thio-β-D-galactoside (IPTG), releases the bound protein from the *lac* DNA This proves, first, that the 1 per cent of 7–8*S* protein which binds to the DNA is indeed *lac* repressor—not just sticky protein—and second, that inducers work by releasing repressors from the repressor DNA complex On the other hand, o-nitrophenyl-β-D-fucoside (ONPF), a substance which binds to repressor but does not induce expression of the *lac* operon *in vivo*, has no effect in the *in vitro* binding of repressor to *lac* DNA, nor does ribonuclease

Gilbert and Muller-Hill have proved that the *lac* repressor binds only to the operator region of the *lac* operon by measuring the binding of repressors to the DNA of two constitutive mutants of the *lac* operon In the absence of inducer, one of these mutants produces *lac* operon enzymes at 20 per cent of the fully induced level, and the other mutant, a low level constitutive, produces only 1 per cent of the full level in the absence of inducers The basal level of the enzymes in wild type cells, in the absence of inducers, is only 0 1 per cent the full level The expression of the *lac* operon in the absence of inducers is explained as a failure of the repressor to bind to the operator site If so, the *in vitro* binding of repressor molecules to the DNA of the two constitutive mutants ought to be weaker by a factor of several hundred for the 20 per cent constitutive and at least ten times weaker for the 1 per cent constitutive than to wild type DNA In binding experiments Gilbert and Muller-Hill have also found, as expected, that the amount of repressor bound to the *lac* operon DNA of the constitutive mutants is less than the amount bound to wild type DNA The repressor, therefore, must bind to a unique sequence in the operator and, because no binding occurs between repressor and denatured DNA, the repressor must bind to double-stranded DNA Ptashne (1967) has shown that this is also the case for λ-phage repressor

On the basis of these isolation procedures, Gilbert and Muller-Hill estimate that each haploid *E coli* cell contains 10 to 20 repressor molecules Each molecule must recognize a stretch of at least 11–12 base pairs, which corresponds to at least one turn of the DNA helix, a stretch of 35 Å The *lac* repressor, with a molecular weight of 150,000, is a sufficiently large molecule to cover this amount of DNA

Now that the Harvard group has established beyond doubt that repressors act by binding to the operator, what comes next? If sufficient crystalline repressor can be isolated, it should be possible to determine by X-ray crystallography the molecular structure of the repressor and the allosteric changes that occur when repressor binds to DNA And, of course, there is still the problem of how, by binding to the operator DNA, the repressor prevents transcription

A New Ribonuclease

from our Cell Biology Correspondent

ZINDER'S group at the Rockefeller University has now reported the discovery and partial purification of a new ribonuclease—ribonuclease III—from *E coli* (Robertson, Webster and Zinder, *J Biol Chem.*, **243**, 82, 1968, and *Virology*, **32**, 718, 1967) Ribonuclease III is apparently specific for double-stranded RNA molecules Because of this unique property—all other known ribonucleases digest single-stranded RNA molecules—RNase III should prove extremely useful as an experimental tool The new enzyme, which occurs in *E coli* loosely attached to ribosomes, is an endonuclease, it attacks RNA chains internally rather than by clipping single bases from one or the other ends of an RNA chain

Robertson *et al* originally detected the enzyme when they found that about 2 5 per cent of the Qβ RNA added to an *S*30 extract of *E coli* to programme *in vitro* protein synthesis was degraded while the rest of the RNA remained intact Because about 2 5 per cent of the RNA isolated from Qβ phage by phenol extraction is known to be double-stranded, they inferred that the *S*30 extract contained an enzymatic activity——RNase III—which specifically digests double-stranded RNAs This they confirmed by digesting other double-stranded RNA molecules, including *R*17 replicative form RNA, reovirus RNA and synthetic double-stranded ribopolynucleotides, with *S*30 extract Tests with *f*2 RNA as messenger, however, showed that the presence of RNase III in the *S*30 extract does not have any gross effect on *in vitro* translation

Starting from these observations, it has now been discovered that the RNase III activity is associated with the *E coli* ribosomes and that it remains bound to the ribosomes at low salt concentrations, but that it is released by washing the ribosomes in buffered 0 2 M (or above) ammonium chloride Unlike RNase I, RNase III is not released from *E coli* cells by osmotic shock Zurdo and his colleagues have partially purified the enzyme, released from ribosomes, on 'Sephadex' columns and find that it has an absolute specificity for RNA molecules containing double helical regions, it has no effect on single-stranded RNA or on single-stranded or double-stranded DNA, and these polymers do not competitively inhibit the digestion of double-stranded RNA This property of RNase III, together with its absolute requirement for Mg^{++} and Mn^{++} and NH_4^+, K^+ and Na^+ cations, its *p*H optimum in the range of *p*H 7 4–*p*H 9 7, and its endonucleolytic activity—the enzyme cleaves internal phosphodiester bonds to yield 3′-phosphate and 5′-hydroxyl groups—clearly distinguish RNase III from any previously described RNase or DNase

RNase III can distinguish between double-stranded RNA and double-stranded DNA, and the secondary structure of double-stranded RNA is closer to the *A* helical form of DNA than the *B* helical form. This suggests that part of the specificity of RNase III resides in the ability to distinguish the *A* form polynucleotide helix. Preliminary experiments have shown that RNase III digests the RNA from a DNA/RNA hybrid. This result supports the suggestion that substrates for RNase III are *A* helices because the hybrid molecule has an *A* helix configuration.

Whatever the function of RNase III *in vivo*, the enzyme will certainly be useful to experimenters. It can obviously be used to analyse the role of double-stranded RNA in RNA phage replication, to produce limited digestion of predominantly single-stranded RNA molecules which have some helical content, and in hybridization experiments to selectively digest the RNA from a DNA/RNA hybrid.

Brain Amines and Drugs

from our Clinical Biochemistry Correspondent

In the past ten years, drugs which affect brain metabolism and human behaviour have been consumed in ever increasing quantities. A biochemical theory of affective disorders has been developed in which depression is the result of a deficiency in the concentrations of serotonin and norepinephrine in the brain, and mania is the converse state with too high a concentration of amines (Schildkraut and Kety, *Science*, **156**, 21; 1967). Much of the evidence comes from animal experiments, and all drugs are developed by experimenting on animals. The relation between biochemical and behavioural effects in different species is therefore of great interest. G. R. Pscheidt (*Comp. Biochem. and Physiol.*, **24**, 249; 1968) has now collected comparative data on the distribution of serotonin and norepinephrine in the brain and of the effects of reserpine, monoamine oxidase inhibitors and lysergic acid diethylamide (LSD).

The hypothalamus usually contains the highest concentration of serotonin and norepinephrine (Amphibia have epinephrine instead of norepinephrine). Birds and fishes are unusual in having relatively high amine concentrations in the telencephalon. The cortex, which is very low in amines, makes up only a very small proportion of the telencephalon in these species. In general, the parts of the brain which are older in an evolutionary sense contain the greatest concentration of free amines, and these are the parts concerned with emotional behaviour.

The monoamine oxidase inhibitors are a group of drugs which are thought to increase the concentration of amines in the brain by inhibiting their breakdown. They certainly do increase the concentration of serotonin in all the species studied, but in the cat, dog and frog the concentration of norepinephrine was not increased. Although large numbers of depressed patients have been treated with monoamine oxidase inhibitors, only one study has shown that they increase amine concentrations in human brain and that was concerned with the action of only one drug. Because animal experiments indicate that there is no correlation with species or drug in the dose of drug necessary to produce a 50 per cent increase of amine concentration, the true effect of these drugs on human brain amines is largely unknown.

Reserpine reduces the concentration of brain amines and produces sedation or tranquillization in all species studied except the frog. (Sedation occurs only if the frog has been pretreated with a monoamine oxidase inhibitor.) When reserpine and a monoamine oxidase inhibitor were given together, the amine concentration was usually intermediate between the concentrations achieved by either drug alone, but in the monkey and rabbit the combination actually gave higher concentrations of serotonin than the inhibitor alone.

Origin of the Diffuse Interstellar Bands

by

Unidentified diffuse interstellar bands may be caused by electronic transitions of impurity ions in grains which are coupled to the lattice vibrations. The 4430 absorption band has a significantly asymmetric profile, being somewhat steeper on the red side than on the blue. This feature is a prediction of the solid state model proposed for the band.

Broad diffuse absorption features, such as the 4430 band, which occur in the spectra of distant stars have defied identification for more than 30 years. The interstellar origin of these bands seems to be beyond serious question and their association with interstellar dust is likely. Most recent attempts at a theoretical explanation of these bands have involved a search for transitions to closely spaced rotational and vibrational energy levels in molecules attached to grains. Herbig[1] has proposed that transitions from the metastable $c^3\Pi_u$ level of the H_2 molecule may account for the 4430 band, but this model can be criticized on account of the unfavourable conditions which exist for the population of the $c^3\Pi_u$ level[2]. More recently, Johnson[3] has proposed that transitions in

Elliott X-ray tube -gives highest specific intensity

Elliott's GX3 rotating anode X-ray diffraction equipment includes an exclusive fine focus cathode system with a rotating anode of high power loading capability. 7kW/mm² (actual area) is available with one thousand hours filament life. The plant includes the rotating anode tube mounted on a robust console which houses the vacuum system, cooling system and all controls. Tube current and voltage are stabilised within ±0.1%. Focal spot sizes are easily interchanged without disturbing the filament and advanced long-life seal design ensures trouble-free operation from the dynamically balanced anode.

Does Energy Data Interest You?

Nearly every operation in industry and in research involves an energy change. How many of the tasks in your field have to do with a change in heat?

A change that may mean you want to measure Heat of Solution, Heat of Adsorption, Heat of Reaction, Heat of Combustion, Heat of Vaporization, Heat of Dilution, Heat of Mixing, Specific Heat of Solutions and so on. Did you know that you could carry out all these measurements with ONE instrument. You can, with

The LKB Precision Calorimetry System LKB 8700

The most versatile instrument available for calorimetric measurement today. Our research team have incorporated in one system the following calorimeters:

General Purpose and Solution · Titration · Heat of Vaporization · Closed-Bomb Reaction · An adiabatic control unit for the study of slow reactions · Rotating Bomb for Heat of Combustion.

Whatever your interest in chemical and physical research, Government, University, Industry, Space Research, National Defence; whatever your end-product, chemicals, oil, rubber, telephones or motor cars, pharmaceuticals or scientific instruments, somewhere along the line you will find you need the LKB Precision Calorimetry System to provide you with accurate thermochemical data.

Write today for full information on this instrument that brings you instantly a complete range of calorimeters; just plug in and choose which one will meet the requirements of the energy change you want to measure.

complex molecular aggregates similar to chlorophyll could be responsible for the diffuse bands. Such a model does not seem to be even remotely plausible because of the lack of suitable conditions for the formation or the stability of such complex molecules in the interstellar medium.

A new line of investigation has recently been suggested[4]. It has long been known that the spectra of certain impure crystals exhibit broad absorption or emission features in the visible and near ultraviolet spectral regions[6-9]. Such bands may in general be attributed to electronic transitions in impurities which are coupled to the lattice vibrations. The widths of such bands may range from ~500–30 Å and the f-values may range from 1 to 10^{-2}. As already pointed out[4], some of these bands bear a striking resemblance to the 4430 band. Assuming that the 4430 band is caused by an electronic transition at an impurity site, we may calculate the concentration of impurities which is required. The absorption cross-section σ_0 near the band centre per impurity ion is given by

$$\sigma_0 = \frac{4\pi e^2}{\gamma mc} f \qquad (1)$$

where f is the oscillator strength and γ is the half-width of the band in frequency units. With $\gamma(=\Delta(c/\lambda))$ as appropriate for the 4430 band we have

$$\sigma_0 \approx 10^{-14} f \text{ cm}^2 \text{ per impurity} \qquad (2)$$

For a star at 1 kpc distance the observed absorption at the centre of the 4430 band is typically ~0.1 mag. In order to produce such an absorption we require a number density of impurities N given by

$$0.1 = \Delta m \cong 1.086\, \sigma_0 N \times (3\times 10^{21}) \qquad (3)$$

that is

$$N \cong 3 \times 10^{-9} f^{-1} \text{ cm}^{-3} \qquad (4)$$

For f in the range 1–10^{-2} and a total grain density $\sim 3\times 10^{-11}$ cm^{-3} we thus require ~10^2–10^4 impurity atoms per grain. Such an impurity concentration would seem entirely permissible in a grain consisting of ~10^9 atoms.

A particular class of defect band which has been studied in some detail is the so-called F-centre in alkali halides. In this case, we have an electron trapped at a negative ion vacancy. A small fraction of such vacancies is present in any crystal at thermal equilibrium, but their concentration could be enhanced by irradiating the crystal with X-rays or thermal neutrons. At such a vacancy an electron is in a potential well which may be approximated crudely by $\varphi = $ constant inside a spherical cavity representing the vacancy and $\varphi = -e^2/\varepsilon r$ outside it. The electron accordingly has hydrogenic energy levels with a $1s$ ground state and a $2p$ first excited level. By the usual selection rules the transition $1s$–$2p$ is strongly permitted with an f-value close to unity. The electronic transition gives rise to a broad band, for each of the electronic levels is split into many phonon states. Experimental results for a large number of alkali halides indicate that the central wavelength of this band depends almost entirely on the lattice spacing d, being approximately $\propto d^{1.8}$ (ref. 10). It varies from ~8000 Å in RbI to ~2500 Å in LiF. The width (at low temperatures) is typically in the range 300–500 Å, considerably broader than the generally recognized diffuse interstellar bands. It is, however, not impossible that such very broad diffuse features exist in stellar spectra, but do not show up above the noise level of the spectrograms. In this connexion it might be possible to attribute the sharp knee at ~4300 Å in the extinction curves of Nandy[11,12] to a weak, but very broad, F-centre at this wavelength superposed on a more gradual change of slope in the extinction curve given by the Mie scattering theory.

A more general class of impurity band is caused by an electronic transition in a foreign ion or radical occupying a lattice site of the crystal. In this case also it is an unfortunate circumstance that most of the available experimental data relate to impurities in alkali halide crystals. The physical processes involved, however, would apply to suitable impurity ions in any crystal lattice; but the central wavelength as well as the width of the band is determined by the particular impurity ion/host lattice combination. The purpose here is to recognize certain general structural features to be expected from these "solid-state bands" and attempt to identify such features with the known interstellar bands.

Wagner and Bron[8] have obtained absorption and emission bands in the blue region with widths ~100 Å for rare earth ions in alkali halide crystals. These bands arise from electronic transitions within the $4f$ configuration and are therefore parity forbidden in the free ion. Lattice vibrations, however, produce a non-zero electric field at the ion and the resulting Stark effect allows a mixing of states with odd and even parities. The net result is that the transition in the crystal becomes weakly permitted with an oscillator strength of ~10^{-2}. Similar effects may be expected to occur for impurity ions belonging to the iron group where electronic transitions may occur within a $3d$ configuration (personal communication from R. J. Elliot).

We urgently require experimental data for crystals of ice and/or graphite with sufficiently abundant impurity species such as Si, Mg, Fe, Ti. Until such data become available we can only hope to identify certain distinctive qualitative features to be expected on the basis of this model.

Let us now consider a very crude representation of the physical process involved. Suppose, initially, that the impurity ion in its ground electronic state is surrounded by host neighbours. Let q_0 be a co-ordinate parameter

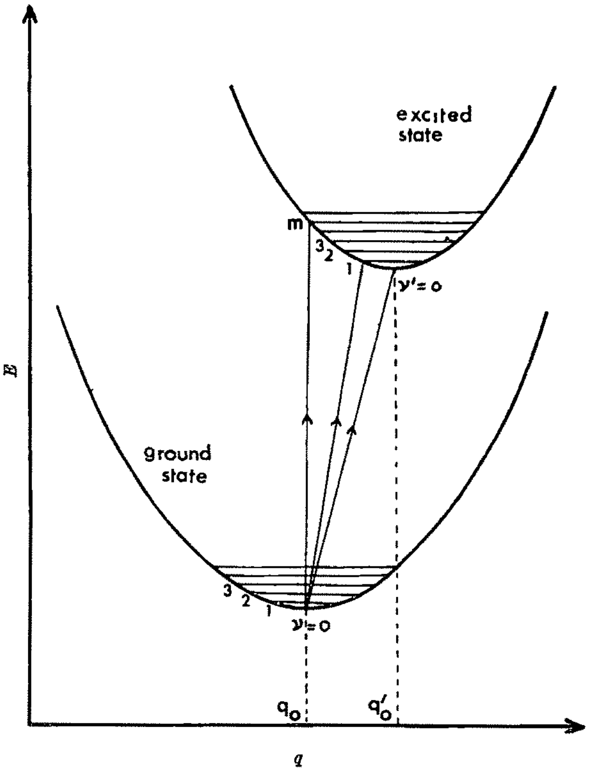

Fig. 1. Schematic energy level diagram showing the vibrational splitting of the electronic energy levels in the impurity ion.

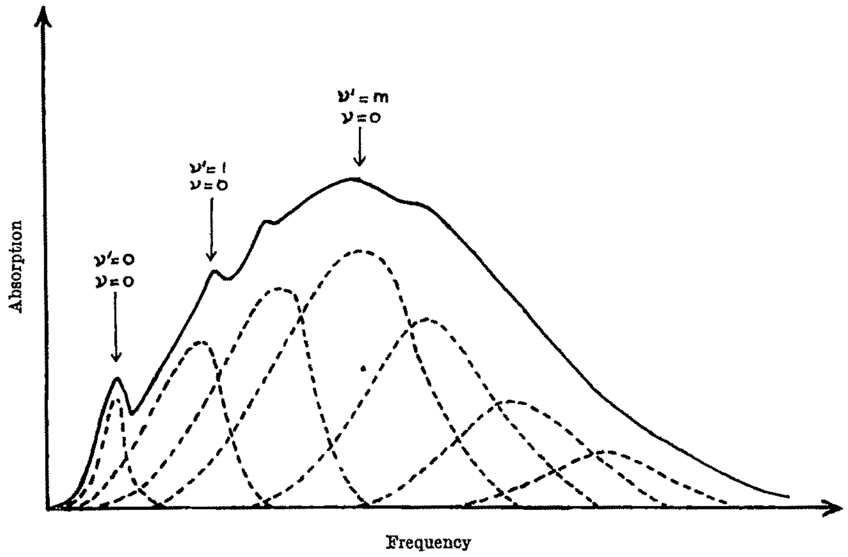

Fig 2 Schematic representation of the absorption profile to be expected due to transitions between phonon states associated with two electronic energy levels The red side of the band is in general steeper and may have more vibronic structure than the blue side (Compare with Fig 6 of ref 7)

which defines its mean equilibrium position relative to the nearest neighbours When the ion is in its upper electronic state the lattice will be locally distorted by the electric fields and q_0 will be increased to q'_0. In either situation the ion may be regarded as a harmonic oscillator vibrating about its mean position with equally spaced energy levels. The energy levels of the entire system may be represented schematically as in Fig 1. $\nu=0,1,2 \ldots$ and $\nu'=0,1,2$. denote the vibrational energy levels associated with the lower and upper electronic states, respectively $\nu'=m$ is the vibrational level of the excited electronic state which lies immediately above the $\nu=0$ level of the ground electronic state The "no phonon" transition from $\nu=0$ to $\nu'=0$ is usually very weak because it is forbidden by the Franck–Condon principle Transitions from $\nu=0$ to $\nu'=1$, 2 . become successively stronger until $\nu'=m$. This transition is strongest according to the Franck–Condon principle For $\nu'>m$ the successive transitions become progressively weaker Fig 2 shows schematically the additive effect of such transitions. The widths of the individual component bands are due to the dispersion of vibrational levels in the lower electronic state. For a more detailed explanation of the shape of these bands we refer the reader to M. H. L Pryce[7] Although varying degrees of asymmetry are found in the experimental solid state absorption bands, the general result which is borne out in Fig 2 is that the red sides of the bands are somewhat steeper and have more vibronic structure than the blue sides (see refs 7–9) The interesting possibility now arises that the predicted characteristics of the solid state band may be subject to an observational verification.

The determination of the precise shape of the 4430 band including the vibronic structures would require spectrograms at very high dispersion—somewhat higher than that available in the results of Seddon[13] Even with the available resolution, however, it may be possible to detect any marked asymmetry, if present, in the 4430 profiles Unfortunately, several stellar lines occur within the 4430 band and it will be necessary to make allowance for them. We have attempted to eliminate the stellar lines by differencing the 4430 intensities in pairs of stars of identical or very similar spectral type, one of which has weak 4430 and the other strong 4430 features Such a procedure would be expected to produce a cancellation of the stellar atomic lines and the residual profile may be

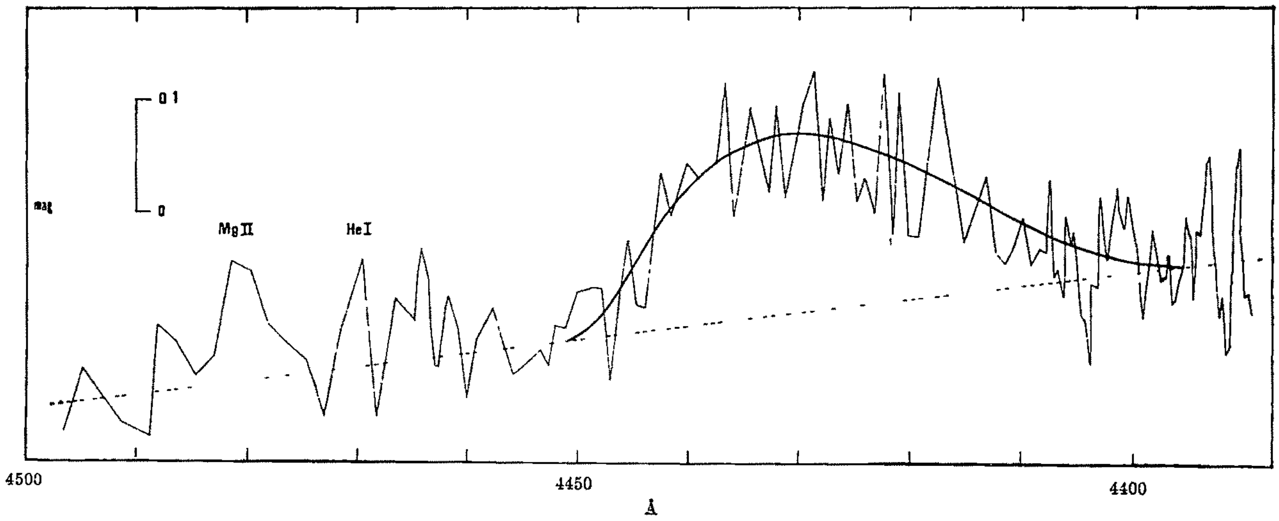

Fig 3 Mean profile of the 4430 band extracted from 3 pairs of stars Heavy line represents the best mean curve through the observational points, smoothing out fluctuations

Table 1 PAIRS OF STARS COMPARED

	Stars	Sp type	E_{B-V}	W_{4430}
(1)	*HD* 224055	*B3Ia*	0 91	2 11
	HD 198478	*B3Ia*	0 60	1 24
(2)	*HD* 224055	*B3Ia*	0 91	2 11
	HD 14134	*B3Ia*	0 67	1 24
(3)	*HD* 43384	*B3Iab*	0 65	1 54
	HD 42087	*B2 5Iab*	0 42	0 98

attributed to the features of the 4430 band including noise Three pairs of stars considered are listed in Table 1

The curve of the mean magnitude differences from the three pairs is plotted in Fig 3. It is interesting to note that the red side of the band is considerably steeper than the blue side, which is in good general agreement with our theoretical expectations (compare Fig 2) The spectral resolution in our data does not, however, permit us to detect vibronic structure which may also be expected on the red side of the band

The attempt by Herbig[14] to detect fine structure in the band occurring in the spectrum of *HD* 183143 was unsuccessful, this investigation may be worth repeating with a differencing procedure such as that employed here

Condensation of the Planets

by

F. HOYLE

N. C. WICKRAMASINGHE

Institute of Theoretical Astronomy,
Cambridge

The early overluminous phase, during the condensation of the Sun can be a great help in understanding why the inner planets are largely made up of iron and magnesium silicate

It is now believed that condensing stars of solar mass are wholly convective, with structures of the kind first investigated by Homer Lane nearly a century ago The surface temperature is maintained at a value of 3,000°–3,500° K during much of the condensation process, eventually rising to ~4,000° K as the immediate pre-main sequence stages are reached These are characterized by a disappearance of complete convection To a moderate degree the star is then sub-luminous compared with the main-sequence state. During the earlier completely convective phases, on the other hand, the star is highly overluminous compared with the main-sequence state The latter is, of course, defined by the condition that nuclear reactions take over essentially the whole energy production, the contribution from gravitation becoming negligible.

In this article we shall examine the problem of the origin of the planets in accordance with the above picture for the early history of the Sun In particular we wish to examine the implication of the overluminous phase of the contracting Sun, especially as it affects the chemical composition of the planets

First, we notice there is clear-cut evidence that the original mass of the planetary material was at least 3,000 Earth masses, as compared with the present planets which total only about 450 Earth masses To see this we note the relative abundances for solar material shown in Table 1

These values are taken from a recent extensive review by Clayton, Fowler and Hoyle (unpublished results) of the abundances of the elements in stars These authors conclude that there is an uncertainty of about ±0 2 in the solar logarithmic abundances of many elements, although the uncertainty for Si may be worse than this because of uncertain *f*-values For our purpose these uncertainties are not, however, important

The densities of the planets Uranus and Neptune are too high (1 56 for Uranus, 2 27 for Neptune) for them to contain much H or He Their densities are appropriate to H_2O, NH_3, N_2, CO_2, after allowance is made for compression If we assume these planets to be largely composed of C, N, O we obtain a minimum estimate of ~3,000 Earth masses for the planetary material This follows because the relative abundances given in Table 1 require C, N, O to comprise about 1 per cent by mass of solar material, so that the ~30 Earth masses of Uranus + Neptune contain the total C, N, O belonging to ~3,000 Earth masses of material of solar composition It is implied here that we regard the planetary material as having originally had the same composition as solar material The estimate is a minimum because it supposes that the whole of the original C, N, O is now present in Uranus and Neptune

An estimate of ~3,000 Earth masses is supported by the Fe content of the inner planets About 30 per cent of the Earth itself is usually supposed to be present in an iron core With Venus possessing a similar structure, the total Fe content of the inner planets is about 0 5 Earth masses, which is the Fe content of some 2,000 Earth masses of solar material This again is to be interpreted as a minimum, for we have no knowledge that the inner planets contain the whole of the planetary iron We shall see at a later stage, however, that there are

Table 1 RELATIVE ABUNDANCE FOR SOLAR MATERIAL

Elements	Logarithm of abundance
H	12 00 (reference standard)
He	~11 0
C	8 5
N	8 06
O	8 80
Mg	7 36
Si	7 3 ?
Fe	6 8

theoretical reasons for believing that this might be the case. Furthermore, the coincidence of this iron estimate from the inner planets with the C, N, O estimate from Uranus and Neptune suggests that the original planetary material probably did constitute some 3,000 Earth masses. The solar mass is ~330,000 Earth masses and so we suggest that the ratio of the masses of the planetary material m to the Sun M was $m/M \simeq 10^{-2}$.

Even this minimum estimate shows that the condensing Sun must have become rotationally unstable at a radius R which much exceeded the present main-sequence radius. That is to say, the planetary material quitted the Sun during the wholly convective, highly luminous, phase of solar contraction. To see this we ask: what has happened to the excess mass, to the difference between $m \simeq 3{,}000$ Earth masses and the present-day 450 Earth masses? The natural answer is that H and He escaped in large quantities from the periphery of the solar system. The excess H and He belongs to the region of Uranus and Neptune and it was from such distances, $r \sim 3\text{–}5 \times 10^{14}$ cm, that these light gases escaped into interstellar space.

The total angular momentum A of the original planetary material must therefore have been

$$A \simeq mr\left(\frac{GM}{r}\right)^{\frac{1}{2}} \qquad (1)$$

the factor $(GM/r)^{\frac{1}{2}}$ being just the orbital velocity at distance r from the Sun. We shall see in a moment why the material may be expected to have been in Keplerian orbits, as (1) requires. First, however, we regard the angular momentum A as having been at one time present in the condensing Sun, and we ask at what radius R the Sun would have become rotationally unstable.

Rotational instability of a condensing gas cloud may be expected to follow the sequence of events described by Jeans[1], in which there is firstly a polar flattening into a spheroidal form which becomes more and more pronounced until the polar diameter is about half the equatorial diameter. At this stage the lenticular configuration develops a sharp edge, requiring material to break away from the main body and to be left behind in circular orbits as contraction proceeds. The condition for this "equatorial shedding" is

$$\frac{\Omega^2}{2\pi G\bar{\rho}} \simeq 0{\cdot}25 \qquad (2)$$

where Ω is the angular velocity and $\bar{\rho}$ is the mean density.

The coefficient on the right hand side of (2) is uncertain within a moderate range. Jeans worked out a number of cases in which the coefficient falls between a lower limit of ~0·19 for an incompressible fluid and ~0·36 for a compressible gas cloud of very strong central condensation. A value of 0·31 is given for a cloud with pressure $P \propto \rho^{2\cdot 2}$, ρ being the density. In our case we expect $P \propto \rho^{5/3}$, because of convection, and for the lower index the coefficient should be less than 0·31. A value ~0·25 therefore seems appropriate.

In (2) $\bar{\rho}$ is the mean density, given by $\bar{\rho} \simeq 3M/4\pi R^3$, so that (2) can be written in the form

$$\Omega^2 \simeq \frac{3}{8}\,\frac{GM}{R^3} \qquad (3)$$

The angular velocity Ω may be expected, because of magnetic viscosity, to be approximately uniform throughout the condensing solar cloud, so that Ω is related to R by

$$Mk^2\Omega = A \qquad (4)$$

where k^2 is the square of the radius of gyration about the polar axis. It is a little difficult to estimate k^2 because of the flattening. We note, however, that whereas k^2 is $2R^2/5$ for a uniform sphere, it is $R^2/2$ for a uniform disk, not much different. This suggests that k^2 will not be much different from the case of spherical symmetry, provided R is interpreted as the equatorial radius. With $P \propto \rho^{5/3}$ for a convective star, we can use the polytrope of index 1·5, for which $k^2 \simeq R^2/5$. Then using (1) for A, and eliminating Ω between (3) and (4), we obtain

$$\frac{R}{r} \simeq \frac{200}{3}\left(\frac{m}{M}\right)^2 \qquad (5)$$

Putting $r \simeq 4{\cdot}5 \times 10^{14}$ cm, close to the radius of Neptune's orbit, and $m/M \simeq 10^{-2}$, (5) gives

$$R \simeq 3 \times 10^{12}\ \text{cm} \qquad (6)$$

There are uncertainties in the numerical value to be used on the right hand side of (2), in k^2, and in the value of r, but all these uncertainties only affect R by factors that cannot be much different from unity. It seems unlikely that R could be less than 10^{12} cm, which is still more than ten times the present radius of the Sun. Indeed, the conclusion that the condensing Sun must have become rotationally unstable at a radius R much greater than present value holds *a fortiori*, because we have used a minimum estimate for m/M. If Jupiter and Saturn contain appreciable quantities of C, N, O, then m/M would have to be increased.

The next question concerns the manner in which the angular momentum A passes from the condensing Sun to the planetary material. Early attempts at a unified theory of the origin of Sun and planets, starting with Laplace, proceeded in terms of gas dynamics alone. It was first pointed out by Alfvén[2] that a magnetic coupling of the Sun and planetary material would tend to maintain uniform angular velocity and that this could lead to a transference of angular momentum in the required sense. One of us[3] showed that without a magnetic torque coupling of the kind suggested by Alfvén the condensing Sun would evolve into two closely separated stars of comparable mass, not into a star and planets. The requirement is for the angular momentum to become stored in a mass m that remains small compared with M. The solar condensation must not remain at the verge of instability, losing more and more material, as it shrinks. Instead the first loss of material must almost immediately take up the angular momentum, so that the Sun is then permitted to contract to the main-sequence without problems of rotational instability arising. This means that the angular momentum A must pass from M to m in a time no longer than that which is required for R to change by a moderate fraction of itself. This time interval is short, because the Sun is in its overluminous state and gravitational energy is being dissipated at a rapid rate. The loss rate is $\pi acR^2T_s^4$, where $T_s \simeq 3{,}000°$ K is the effective surface temperature. The gravitational energy is $\sim GM^2/R$, and the time required for R to shrink by an appreciable fraction of itself is

$$\sim \frac{GM^2}{R}\Big/\pi acR^2T_s^4 \approx 5{,}000\ \text{yr} \qquad (7)$$

when (6) is used for R. The angular momentum must be transferred from M to m in a time less than (7). Using the same method as was used formerly[4], it can readily be shown that a magnetic field with an intensity $\sim 10^2$ gauss would be needed to effect the transference in the required period. This is a considerably stronger field than that which was formerly calculated because the previous work did not take account of the overluminous phase. Nevertheless, a field of $\sim 10^2$ gauss is still not unreasonably high. When compressed by the continued shrinkage of the Sun to the main-sequence state the field strength would become $\sim 10^5$ gauss. It is an attractive possibility that the fields of up to 3,000 gauss still observed at the solar surface represent a decayed residue of this initial field.

The transference of angular momentum causes the planetary material to move outwards from the Sun. It must indeed move largely out to $r \simeq 5 \times 10^{14}$ cm in order to store the angular momentum. With increasing r the temperature of the material falls, approximately as

$$T \simeq T_s\left(\frac{r}{R}\right)^{\frac{1}{2}} \qquad (8)$$

and depending on their concentrations and saturation vapour pressures various substances condense out of the gas as T falls The density falls like

$$\rho \sim \frac{m}{r^3} \times [\text{Numerical factor of order unity}] \qquad (9)$$

the numerical factor depending on the degree to which the planetary material becomes flattened into a disk

Starting with material of solar composition we have carried out extensive computations of the thermodynamic properties of the planetary material, treating the system as a dissociating assembly of molecules, and including the formation of solids and liquids The density ρ was taken to fall as T^6, in accordance with the proportionalities suggested by (8) and (9), and the behaviour of the material was studied as a function of T Fig 1 shows the concentrations of a representative sample of molecules arising from such a calculation for the case $m \simeq 3{,}000$ Earth masses The calculations are much more sensitive to T than to ρ, so that the precise value chosen for the numerical factor in (9) was not very important The calculations were in fact performed for various values of the product $m \times$ [Numerical factor of order unity] About a hundred molecular species were included in the calculations, which led to details that go much beyond the scope of this article Here we are concerned only with the materials that condensed from the gas phase into the solid phase—no liquids were formed within the range of our calculations

The solids fell into two categories. refractory materials that condensed at temperatures above 1,000° K, and volatile substances condensing at low temperatures. The most important refractory materials were MgO, Fe and SiO_2 It is to be noted that the iron was given the opportunity to condense in a non-metallic form, for example, as the sulphide and oxides, but it was the metal phase that actually condensed The respective temperatures were ~1,600° K for MgO, ~1,500° K for Fe, and ~1,400° K for SiO_2 The temperature for silica was the lowest because at higher temperatures the silicon was overwhelmingly in the form SiO, which we took to have the rather low heat of vaporization of 65 Kcalories/mole. A significantly higher value, say, 100 Kcalories/mole, would have the effect of solid SiO appearing at ~1,600° K Unfortunately, there are no good data for the heat of vaporization of SiO, but we are informed that a low value is more likely to be correct than a high value

It is clearly significant that the inner planets are largely composed of Fe and of $MgOSiO_2$ in various mineral forms We also see why the inner planets contain an appreciable fraction of the total Fe and $MgOSiO_2$ contained in the whole of the planetary material Taking 1,500° K as a mean condensation temperature and setting $T_s \simeq 3{,}000°$ K in (8), we have $r \simeq 4R \simeq 1\ 2 \times 10^{13}$ cm, when (6) is used for R It is satisfactory that this value falls between the radii of the orbits of Venus and the Earth

The first volatile to condense was H_2O, at $T \simeq 150°$ K Again using (6) and (8), $r \simeq 400R \simeq 1\ 2 \times 10^{15}$ cm, comparable with but rather greater than the radii of the orbits of Uranus and Neptune Condensation at somewhat smaller values of r is indeed to be expected because (8) assumes that the solar radiation is not strongly absorbed within the planetary material Should the material become opaque, as it eventually does through absorption by water vapour in the infrared, the temperature must fall off more steeply with increasing r than is given by (8) This is because the material has a disk structure, so that a non-isotropic situation then occurs with the radiation being emitted normally to the disk, instead of continuing to propagate freely in directions parallel to the disk. The relevant strong water vapour band is centred at about 6μ When T falls so that the black-body curve has its peak at about 6μ, that is, when T falls to ~500° K, the opacity becomes large and T can be considered to fall quite steeply with r Using (8) again, but now with $T \simeq 500°$ K, leads to $r \simeq 36R \simeq 10^{14}$ cm, somewhat less than the radius of the orbit of Saturn An ambitious investigation, taking account of the geometry of the disk and of opacity effects, would be necessary to determine the details of the condensation process, but we see that the condensation of H_2O, and of the next most important volatile CO_2, extends to values $r \simeq 3 \times 10^{14}$ cm, although some condensation may occur at radii within the orbit of Saturn

This work differs from previous investigations in that we have taken account of the overluminous phase of the condensing Sun As far as the broad features of planetary condensation are concerned, this has many advantages First, if there were no high luminosity phase the volatiles would condense at too small values of r, near Jupiter rather than beyond Saturn Second, it is easier to understand the escape of H and He from the region of Uranus and Neptune, for $r = 3 \times 10^{14}$ cm, $R = 3 \times 10^{12}$ cm, $T_s = 3\ 900°$ K in (8) gives $T = 300°$ K Because of the shielding effect of water vapour at $r < 3 \times 10^{14}$ cm, this is an overestimate, but even allowing for the opacity due to water vapour we expect a temperature appreciably above the former value of 75° K or less[3] Third, the refractory materials condense in the region of Venus and the Earth, farther

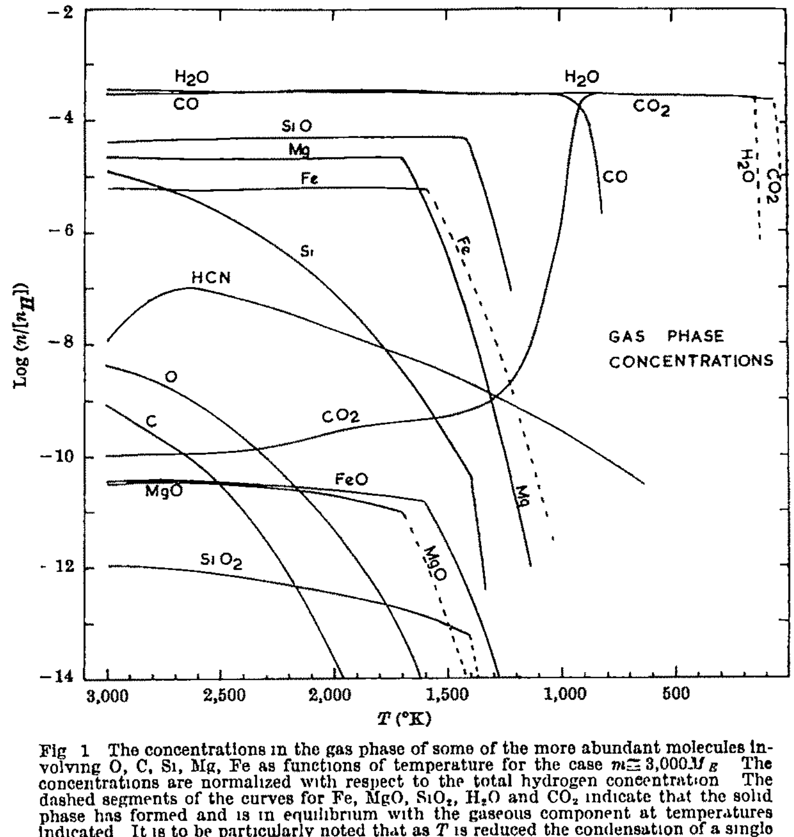

Fig 1 The concentrations in the gas phase of some of the more abundant molecules involving O, C, Si, Mg, Fe as functions of temperature for the case $m \simeq 3{,}000 M_E$ The concentrations are normalized with respect to the total hydrogen concentration The dashed segments of the curves for Fe, MgO, SiO_2, H_2O and CO_2 indicate that the solid phase has formed and is in equilibrium with the gaseous component at temperatures indicated It is to be particularly noted that as T is reduced the condensation of a single species involving a particular metal is accompanied by a steep drop in the concentrations of all species involving that metal As T falls, the metal (for example, Mg, whether as Mg metal or as MgO) is quickly drained out of the gaseous phase into the condensed phase

out than would be the case if the Sun had low luminosity. Fourth, at a temperature of 1,500° K metallic iron is sticky and likely to aggregate quickly into large lumps The MgO and SiO_2 could well have condensed as a fine smoke which continued to be carried along by the outward moving gases except when it became mixed in with the metal This could well explain the puzzling discrepancy between the ratio (Mg+Si)/Fe in the Earth and in the Sun In the Earth the mass ratio is $\sim 1/1$, whereas in the Sun it is $\sim 3/1$ The lumps of metal only succeeded in promoting the aggregation of about one-third of the $MgOSiO_2$ Fifth, it was previously supposed that the Earth aggregated as a cold body and this made it difficult to understand how the Fe in the Earth has managed to sink through to the centre With the Fe already in considerable lumps, and with the temperature greater than 1,000° K, this is now not so difficult Furthermore, the plastic flow of considerable lumps towards the centre would itself release energy that would raise the temperature considerably, as was first pointed out by Urey[4] It seems probable that the concept of an initially cold Earth will have to be revised, with a return to the earlier idea of a molten Earth[5], or at any rate to an Earth with large scale convection

An important question remains how did it come about that the Earth acquired volatiles, in particular H_2O, CO_2, N_2? Once the Earth had formed as a strongly gravitating body, it could acquire some volatiles by accretion from a solar wind The target area of the Earth for such a process, however, would be quite small It seems preferable therefore to argue that, although the main aggregation of the Earth may have occurred very quickly, say, in $\sim 10^4$ yr during the high temperature phase, a good deal of debris in the form of modest-sized planetesimals continued to be present for a time at least of the order of the time required for the Sun to reach the main-sequence, more than 10^7 yr This would include the overluminous phase that preceded the main-sequence state Further ejections of material, such as are observed in *T* Tauri stars, would lead to the condensation of volatiles at much smaller values of *r* These might well have become added first to the planetesimals, and later to the Earth and other inner planets as the planets continued to mop up the smaller bodies

It may also be worth noting in this connexion that Fe and $MgOSiO_3$ condense in an atmosphere containing high concentrations of H_2O, CO and N_2. It is possible that significant quantities of these volatiles become trapped as impurities within the refractory solids

Prodromus of the Comparative Serology of Marsupialia

by
J. A. W. KIRSCH
Department of Zoology,
University of Western Australia,
Nedlands, Western Australia

Serological data, and the information about phylogeny which they supply, can be used as the basis of a revised classification of the Marsupialia

In spite of the great interest of marsupials to mammalogists, and a number of thorough and excellent taxonomic reviews which have appeared since marsupials were discovered[1–7], several problems of marsupial systematics remain unsolved This is largely because there is a poor understanding of the phylogeny of the group, which is in turn related to the paucity of Tertiary fossil material in Australia In this situation only the features of the living animals can provide clarification of marsupial affinities and relationships Accordingly, there has been in recent years an increase in interest in the systematic application of neontological characters to marsupials, often by workers who are not taxonomists in the classic sense Thus we now have a large body of data, taxonomically oriented, on marsupial reproductive anatomy and physiology[8–11], cytology[12–14] and sperm morphology and behaviour[15,16] Serology, however, has so far contributed little to marsupial systematics[17,18], and it was this omission, together with an awareness of the potential of serology in taxonomic work, which provided the stimulus for the present study Only three species of American marsupials have been included, but the coverage of the Australian radiation is comprehensive, and embraces about 1,800 individuals of eighty species, representing thirty-nine genera from all but one of the extant families listed by Simpson[19] A few results have already been reported (refs 20 and 21, and my unpublished work), but it will be some time before the details of this work can be published in full, and so it seems desirable to present a summary statement now A new classification of marsupials, incorporating the serological data, is also presented here, a detailed rationalization of this scheme will be given later

Standard serological techniques, including double-diffusion and immunoelectrophoresis in agar gels, nephelometry, starch-gel electrophoresis and the haemagglutination inhibition test, were applied to the study of the serum proteins of marsupials The greater part of the data summarized here came from the immunoelectrophoretic tests, which involved extensive use of preabsorbed antisera The results were scored and interpreted by a variety of techniques, including an original method of "logical analysis", and Goodall's probabilistic similarity index[22] was computed for certain sections of the data A feature of the study was the use of antisera prepared in marsupials this proved advantageous in studying families which contain numerous very closely related species (for example, Macropodidae)

As a group, the marsupials are more similar serologically to eutherian mammals than they are to monotremes (*Tachyglossus*), a point which accords well with contemporary concepts of the interrelationships of mammals[19] Fig 1 summarizes the serological affinities of forty-one marsupial genera to each other, generic limits are largely those adopted by Ride[23]. Fig 1 is neither a phylogeny—although it has phylogenetic implications—nor a classification The conventions of this phenogram are the usual ones, that is, the linkages represent groupings of increasingly similar taxa proceeding from left to right on the horizontal axis. The scale of the abscissa is roughly linear, but the ordinate has no dimension, and proximity of taxa in the vertical dimension does not necessarily indicate special affinity

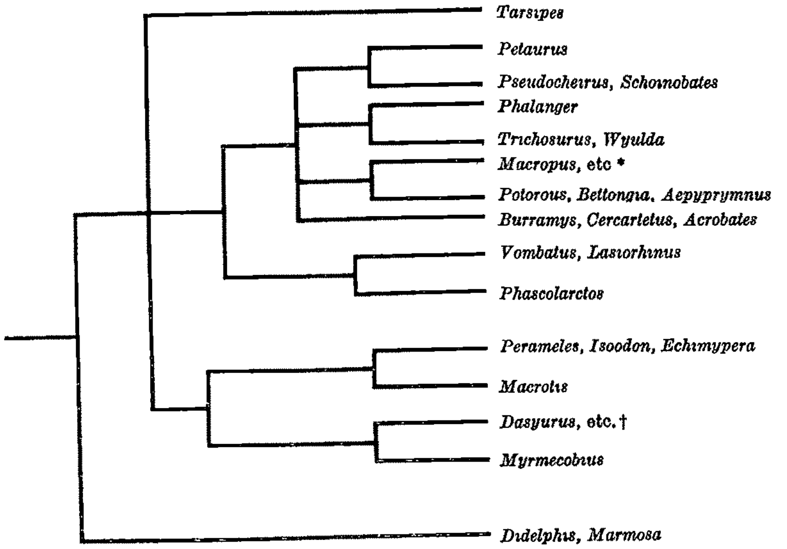
In many respects the groupings indicated by serology correspond to those of the generally accepted classification of marsupials[19] For this reason the details in which the serological clusterings differ from that arrangement are particularly interesting (1) The American marsupials, at least as represented by *Didelphis* and *Marmosa*, stand apart from all of the Australian genera, this result confirms the similar finding of Weymss[18] (2) The Australian marsupials comprise three groups *Tarsipes*, the remaining phalangeroids, and the peramelids plus dasyurids (including *Myrmecobius*) (3) *Phascolarctos* is most similar to the wombats (*Vombatus, Lasiorhinus*), and not to the "phascolarctine" possums (*Schoinobates, Pseudocheirus* and closely related genera) (4) The Phalangeridae, excluding *Phascolarctos* and *Tarsipes*, comprise at least three groups as distinct from each other as they are from the Macropodidae

The phenogram does not show in detail the affinities of the genera in diverse families such as Dasyuridae and Macropodidae Seven genera of dasyurids (apart from *Myrmecobius*, which represents a distinct line within Dasyuridae) have been examined *Dasyuroides, Sarcophilus* and *Dasyurus* (all species but *D maculatus* were tested) are very close, and *Sarcophilus* might be considered an aberrant member of *Dasyurus* *Sminthopsis* and *Antechinomys* form a second genus-group, and both groups are equally distinct from a third, consisting of *Phascogale* and *Antechinus* (including *Pseudantechinus*). The latter grouping is complicated by suggestions that *Antechinus* may represent more than one genus, and *A rosamundae* appears to be closer to *Dasyurus* than to *Phascogale-Antechinus*

The usual sub-familial arrangement of the Macropodidae is supported by serology, but Woodburne's recent suggestion[24] that *Dorcopsis* be included in the Potoroinae is not upheld; *Hypsiprymnodon* and *Caloprymnus* have not yet been examined Within Potororinae, *Bettongia* and *Aepyprymnus* form a group distinct from *Potorous* Species of all macropodine genera but *Dorcopsulus* and *Peradorcas* have been studied, and these experiments show that the strongest genus-group in Macropodinae is of *Thylogale* and *Petrogale*, with which *Setonix* and probably also *Lagostrophus, Dendrolagus* and *Dorcopsis* are associated The interrelations of the last three genera are still uncertain A second group of genera is represented by the kangaroos and wallabies of *Macropus* (sensu Calaby[25]), but on serological grounds this genus includes *Megaleia* and *Wallabia bicolor*. *Lagorchestes conspicillatus*, the single species of *Lagorchestes* available for study, is associated with *Macropus* *Onychogalea* appears to represent a third group of macropodines

The phylogenetic implications of data such as these are usually inferred by assuming that the similarities among organisms are proportional to their relationships, that is, that evolutionary change has been a regular function of time in each lineage If this is so, it is easy to establish the cladistic relationships of a group of living organisms from a consideration of their phenetic affinities. At the same time, the assumption of "time-dependent" evolution has certain logical consequences, the most obvious being that, with respect to the characters studied, no living organism is more primitive than any other Assuming time-dependency for biochemical or serological characters therefore precludes the possibility of discovering the relative primitiveness of members of the studied group, which is another, equally valid, aspect of phylogeny. Biological and theoretical considerations, as well as a large portion of the present and other published data, indicate that time-dependency cannot possibly hold true in detail for marsupial serum proteins; a further treatment of the problem is the subject of a paper now in preparation.

If any conclusions at all are to be drawn from the data of Fig 1, the assumption of time-dependency must be made, and its usefulness as a generalization for at least the broader aspects of marsupial relationships can only be assessed on the basis of the reasonableness of the resulting phylogeny Proceeding in this fashion, the results suggest that the Australian radiation is distinct from the American (at least, didelphid) radiation in this regard it would be most interesting to examine blood from caenolestids Within the Australian group, the dasyurids and peramelids must represent recent derivatives from the (presumably polyprotodont) stock, and thus neither family can be imputed to represent the ancestors of Phalangeroidea *Tarsipes*, which is so distinct from the rest of the Australian marsupials, presents a difficult and in many ways critical problem Recent unpublished work of Yadav at the University of Western Australia has shown that, in common with other Australian diprotodonts, *Tarsipes* possesses a superficial thymus gland, and this, together with its diprotodonty and syndactyly, would seem to remove all doubt that *Tarsipes* is a true phalangeroid Thus the only reasonable interpretation of the serological data is that this animal represents a lineage that arose from the Phalangeroidea as early as the basic polyprotodont–diprotodont division of Australian marsupials The remaining phalangeroids consist of two lines. koala–wombats and possums–kangaroos The latter comprises four equally related groups of genera, and in this sense "the macropodids are simply leaping phalangistids[26]"



* *Macropus*, etc , includes *Macropus, Megaleia, Wallabia, Lagorchestes, Lagostrophus, Setonix, Thylogale, Petrogale, Dendrolagus, Dorcopsis* and *Onychogalea*

† *Dasyurus*, etc , includes *Dasyurus, Dasyuroides Sarcophilus, Antechinus, Phascogale, Sminthopsis* and *Antechinomys*

Fig 1 Phenogram showing the serological affinities of forty-one marsupial genera The linkages represent groupings of increasingly similar taxa from left to right The scale of the abscissa is roughly linear, but the ordinate has no dimension

The serological data, and the data of phylogeny which they imply, can be considered together with all the other available information about marsupials as the basis for a revised classification of Marsupialia. The classification which follows purports to do this, but only a few comments in support of this arrangement can be made here It is likewise beyond the scope of this article to discuss nomenclature in detail, but as far as possible names have been chosen in accord with the provisions of the International Code of Zoological Nomenclature (second edition) A personal convention in this matter is that where the author did not use a family-group name at the indicated level, date and authorship are given in parentheses

I follow Ride[7] in considering the marsupials to represent several orders, for his reasons and also because this makes available a greatly expanded hierarchy for showing affinities and supposed relationships In such a multiordinal scheme, the Australian diprotodonts (Diprotodonta) and caenolestoids (Paucituberculata) represent two principal groups In spite of the separation of Australian and American marsupials on serological and other[16] grounds, I agree with Ride that it is useful to place the American polyprotodonts and the dasyuroids in a single order; however, unlike Ride, I believe that there are compelling reasons for including the peramelids in this order, and I would not separate them from it as he did To show the breadth of this third order (Polyprotodonta) as compared with the other two, I use suborders in it but not in Paucituberculata or Diprotodonta Gill's names are available for two of the suborders, and I propose the new name Peramelemorphia for the third

Because knowledge of fossil American marsupials is rapidly expanding, and the Didelphoidea have been revised recently[27], I do not offer opinions on the organization of the American marsupials below the level of superfamily. I have considerably reorganized Diprotodonta, however, as shown in the classification Here, *Tarsipes* is placed in a monotypic superfamily, somewhat compromising the serological results, and the koala and wombats are grouped as two families of another superfamily Phalangeroidea is restricted to the possums, kangaroos, and several extinct groups—inclusion of Diprotodontidae is somewhat tentative, however. The possums are reorganized into three families, the distinctness of which is supported by what is known of their cytology (refs 12 and 14 and unpublished work of M M Gunson, G B Sharman and J A. Thomson) and sperm morphology[15], this arrangement more adequately expresses what I believe to be the phylogenetic relationships of living phalangeroids Burramyidae may include *Distoechurus*, but *Dactylopsila* (including *Dactylonax*) is aberrant in so many respects that its affinities, like *Notoryctes*, can only be a matter of conjecture at present

This study formed part of a thesis submitted to the University of Western Australia, and was carried out while I held, successively, Fulbright student and US National Science Foundation graduate fellowships Funds were made available by the Research Grants Committee of the University of Western Australia, and a few experiments were carried out during my tenure as experimental officer with the CSIRO Division of Animal Health, McMaster Laboratories, Glebe, New South Wales, Australia

I thank the many people who helped me obtain or provided me with marsupial sera. I also thank Dr W. D L Ride for encouragement and criticism, and John Calaby for advice on nomenclature Mohan Yadav allowed me to quote from his unpublished researches on the superficial thymus

Heteropsammia michelinii, a free-living and free-moving scleractinian coral found in the Australian Great Barrier Reef, has a symbiotic association with a sipunculid worm, *Aspidosiphon corallicola*. The worm lives in a cavity on the under surface of the coral and it pulls the coral over the muddy surface of the sand.

SCLERACTINIAN corals are usually regarded as sessile organisms, providing the principal substance of coral reefs. We should like to record, however, some observations on a community of free-living and free-moving species of scleractinian corals which we found during October 1967 while we were participating in the Belgian De Moor Expedition to the Australian Great Barrier Reef. This community occurred at depths of around 12 m in the lee, that is north-west, of Lizard Island, at lat. 14° 39·5′ S. and long. 145° 26·5′ E. (Australian Survey Map SD 55.9, Grid Reference 334143). This granite mass is the highest of the continental islands within the northern half of the Great Barrier Reef. It is extensively vegetated, rises to a height of 382 m and provides the greatest shelter from the prevailing south-east trade winds. On the lee side, a gently sloping shelf 10–14 m deep extends to about 2 km from shore. The sediments of the outer part of the shelf consist of a relatively unsorted mixture of granite, sand, shell and *Halimeda* fragments, with a surface layer of detrital mud. The bottom has the "trampled" uneven appearance characteristic of sediments in which there is a large population of burrowing forms. Most of our collections and underwater observations were made about 1·5 km from the nearest reef.

There is a patchy flora of *Caulerpa*, *Avrainvillea*, *Udotea*, *Halimeda*, *Penicillus* and filamentous blue green algae. Benthic invertebrates include sponges, cerianthids, pennatulids, holothurians, crinoids, asteroids and some tunicates, more rarely *Pinna* sp. (*carnea* ?) and the white hammer oyster *Malleus albus*.

The coral population consists of *Cycloseris cyclolites* (Lamarck), *Diaseris distorta* (Michelin), *Heteropsammia michelinii* (M.E. and H.), and more rarely *Trachyphyllia geoffroyi* (Audouin). They are all free-living and except for *Trachyphyllia* have the corallum totally enclosed by living coenosarc. It is possible that *T. geoffroyi* is not typical of this environment, for it is found more frequently on clean shell and coral talus near the base of reefs where it begins life fixed to a hard substrate. The other species, *Cycloseris*, *Diaseris* and *Heteropsammia*, occur only on soft bottom, and they are never found on reefs.

It is paradoxical that all these forms by definition belong to the category of hermatypic (reef-building) corals because they contain zooxanthellae. In an ecological sense, however, they are ahermatypes (non-reef-builders) because their solitary free-living mode of life on the muddy bottom precludes participation in the process of reef-building. It is perhaps interesting that in the sub-order *Dendrophylliida*, *Heteropsammia* is one of only two genera known to contain zooxanthellae, the other being *Turbinaria*, an important Indo-Pacific reef-building coral.

Of the two fungiids, *Diaseris distorta* is the most numerous. It occurs in more or less dense patches some of which were estimated to contain more than a thousand individuals in a square metre. Most of the coralla are less than 1 cm across; they rarely reach to 2 cm, and are thin and flat. Several thousand *Diaseris* were inspected at Lizard Island; each showed traces of breakage along the septal radii, with subsequent regeneration from the

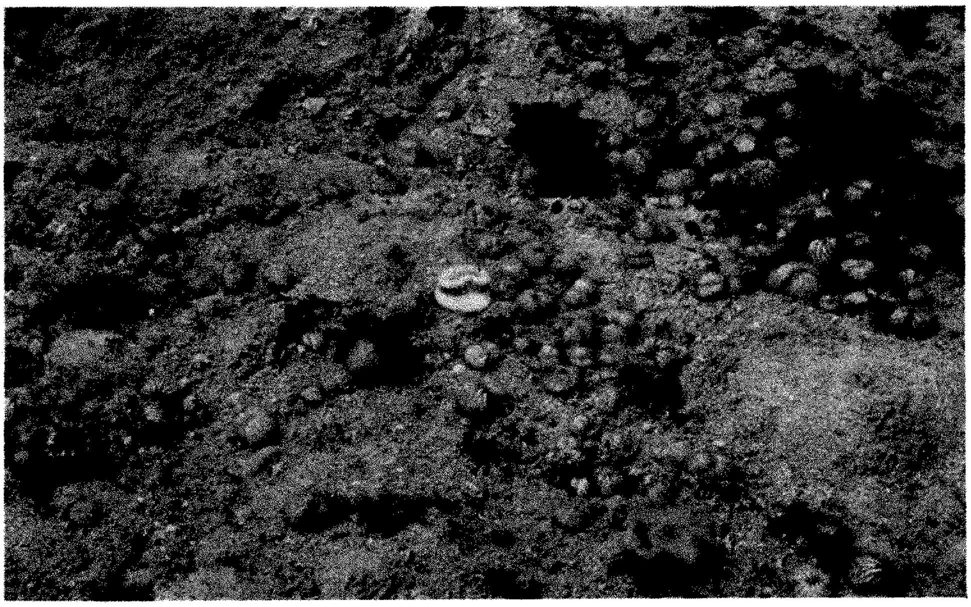

Fig. 1. Mixed community of *Heteropsammia michelinii*, *Diaseris distorta* and *Cycloseris cyclolites* at a depth of about 16 m on muddy silt bottom off Lizard Island. The most abundant coral in this field is *Diaseris*, small groups of which are congregated in hollows on the uneven bottom. Five *Heteropsammia* are visible in the foreground, and a single *Cycloseris* lies among the *Diaseris* on the right side of the photograph. All the corals here are fully expanded. The scale is given by the *Heteropsammia*, which are approximately 2 cm across.

stomodeal end. All the coralla were, as a result, asymmetric; indeed, most of the small individuals (less than 5 mm) were no more than wedge-shaped segments suggesting a very rapid rate of fragmentation. These corals, however, showed no signs of mechanical damage or injury as might be expected if the breakages were caused by external factors, such as browsing fish. It was also common to find specimens where the corallum was broken but the pieces were still held together by the tissues, which were intact and normal in appearance. The frequency of such skeletal breakage occurring without any obvious mechanical injury suggests that this may be a normal process of physiological segmentation, that is, asexual reproduction by transverse division of the anthocyathus instead of the anthocaulus, the latter being the usual method of increase among other monostomodeal fungiids[1]. This would explain the distribution of *Diaseris* in dense isolated patches each perhaps representing a clone, and also our failure to observe or collect any anthocauli of this species.

Cycloseris cyclolites is larger, dome-shaped and slightly oval. A typical individual has major and lesser diameters of 3·8 and 3·4 cm, respectively, and a height of 1·5 cm, the aboral surface being deeply concave. The coralla are fairly symmetrical and only a few showed healed scars caused by breakage and regeneration.

Both fungiids are usually expanded during the day. There are numerous small tentacles that retain particulate material which is carried to the stomodeum by local reversal of flagellar currents. When the corals are not feeding, the direction of these currents is towards the periphery, as in larger fungiids[2]. *Cycloseris* and *Diaseris* possess remarkable powers of movement. They are able to creep slowly over the bottom, right themselves if turned over and extricate themselves if buried by sediment. When corals of both species are mixed with their natural substrate and placed in a dish so that they are covered by mud, all the individuals gradually rise to the surface with their oral sides uppermost, that is, they uncover and, where necessary, turn over as originally described for larger fungiids by Marshall and Orr[3] and by Abe[4]. *Cycloseris* frees itself from mud by means of a combination of flagellar currents and tentacular movements. *Diaseris* in addition takes in water through the stomodeum; the resulting turgor causes the polyp to swell to more than double the size of the skeleton and so reduces its density that the animals literally "float" to the surface of the sediments. When the corals finally come to rest on top, they are surrounded by a well marked ridge of mud which has been carried off the oral surface by the combined action of the flagella and mucus. Compared with the larger fungiids, which usually occur in shallow turbulent zones on coarse sand or coral fragments, these smaller species are clearly very highly specialized for life on soft muddy substrates, in relatively calmer or deeper environments.

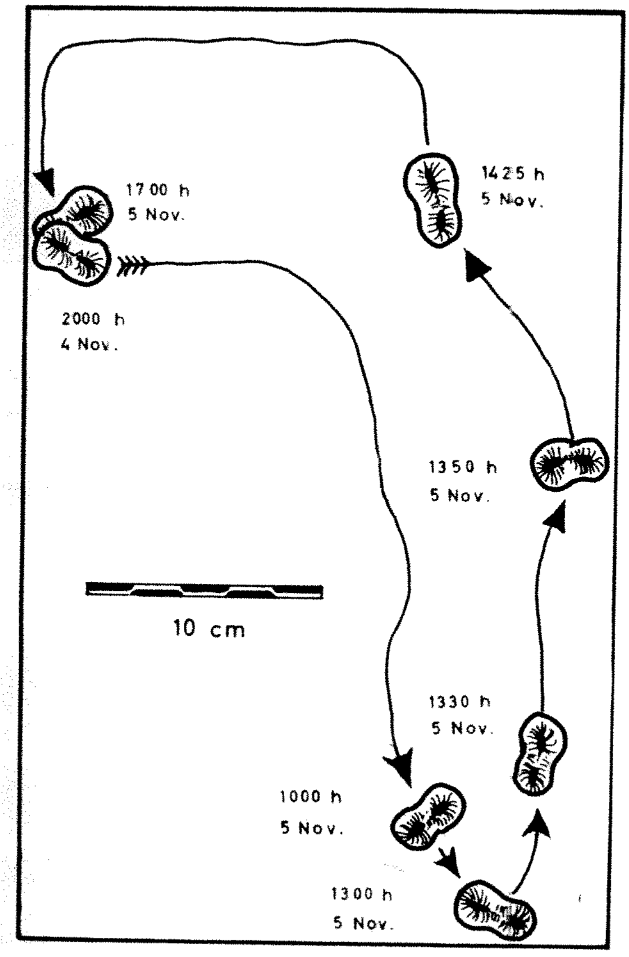

Fig. 2. Migration of a single *Heteropsammia michelinii* in a tank between 2000 h, November 4, and 1700 h, November 5, 1967. The path shown by the arrows is the trail left by the coral as it was being dragged along by its associated sipunculid worm *Aspidosiphon corallicola*.

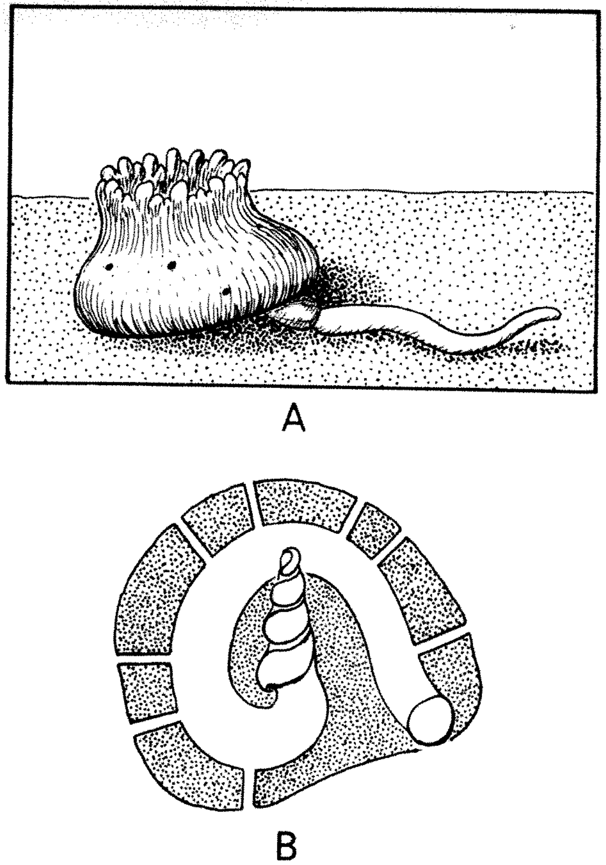

Fig. 3. *A*, *Heteropsammia michelinii* (in aquarium) with sipunculid reaching out from opening of cavity. Note openings of pores extending from this to exterior. (Redrawn after Bouvier[6].) *B*, Horizontal section through *H. michelinii* showing original gastropod shell and the spiral cavity extending from this occupied by the sipunculid, also pores, of unknown origin and function, extending to exterior. (Redrawn after Schindewolf[8].)

At Lizard Island, *Heteropsammia michelinii* occurs scattered among the *Cycloseris* and *Diaseris* (Fig. 1) and is of even greater interest. Completely free-living, each individual consists of a squat round base, with a column about 2 cm across and 1 to 2·3 cm high, crowned by one or two, rarely three, polyps. The upper calicinal surface is often wider than the base; such coralla tend to be unstable and they can topple over.

The most striking feature is the presence on the under surface of a rounded opening about 2 mm across which leads into a coiled cavity inhabited by a sipunculid worm, *Aspidosiphon corallicola* (Sluiter, as quoted in Vaughan and Wells[5]) There was little time for observations in life, but the worms were seen to emerge from the openings probing the sediments while retaining a very firm hold in the cavity They thus pull the corals over the surface of the muddy sand This movement is sporadic as shown by the track of a *Heteropsammia* on its natural substrate in an aquarium during a 21 h period (Fig 2), the wandering of the animal being clearly marked by the trail left in the sediment In their normal environments at Lizard Island many of the *Heteropsammia* were lying on their sides and a few were even upside down In one case the worm was seen to jerk the coral upright with one powerful movement The polyps are usually expanded, the tentacles reaching lengths of more than 10 mm Individuals leaning on their sides usually have their tentacles sweeping the bottom, and it is possible that they can collect in this way particular food of animal origin deposited on the sediment surface If this is so, then the activities of the commensal worm will be of great value as it continually moves the coral to the new feeding areas The sipunculid reaches down to feed in the subsurface sediments and does not compete for food with the coral

The only previous observations in life seem to be those communicated by Jousseaume to Bouvier[6] on which were based a figure, part of which is here reproduced (Fig 3*A*) The initial association is similar to that found in the sipunculid *Phascolion strombi*, which occupies empty shells of *Apporhais pes-pelecani, Dentalium entalis* and *Turritella communis* in European seas As first indicated by Milne Edwards and Haime[7], the further development of symbiotic relationship between sipunculid and coral involves settlement of planulae on similarly occupied gastropod shells As the coral comes to envelop the shell, the cavity of this is continued, still spirally wound but of much wider lumen (Fig 3*B*) This opens on the under side conferring a certain secondary bilaterality on the coral[8] The sipunculid cannot bore, but its active presence will modify the growth of the coral just as the external settlement of associates such as the bivalve *Pedum spondyloideum*[9] affects that of the "host" coral A series of minute passages of unknown function and certainly not formed by the worm open to the exterior (Fig 3*A* and *B*) In some cases (not personally observed) a calcareous secretion may cause slight constriction of the opening of the cavity. The sipunculid probably produces the secretion and it may assist it to retain firm contact while it explores the substrate The whole association, extended to cover a diversity of organisms connected with one or other of the symbionts, is briefly described by Schindewolf[8] It includes the small, byssally attached erycinacean bivalve, *Jousseaumiella heteropsammiae* Bourne (noted by Dr A Coomans), just within the opening of the cavity although it does also occur on the body of the sipunculid[10]

We thank Professor M Dubuisson for inviting us to participate in the work of the Belgian Great Barrier Reef Expedition We also thank Professor A Distèche, leader of the expedition, and his colleagues on the scientific staff, Commander A Robyns and the officers of the Royal Belgian Navy Frigate De Moor, and also Professor J W Wells for identifying the corals and discussing our manuscript

Mechanism of Olfactory Transduction

by

BARNETT ROSENBERG

ROBERT SWITZER†

Biophysics Department,
Michigan State University,
East Lansing,
Michigan

A possible mechanism for olfactory transduction depends on the formation of a weak bound complex between an absorbed gas molecule and certain carotenoid pigments.

A THEORY of the olfactory transducer must satisfy several well established criteria The interaction energy between the odorous molecule and the receptor site must be a weak one—on the order of a few times kT—to allow rapid disappearance of the first signal when the surrounding atmosphere is changed and a second type of odour occurs Despite this weak interaction, it must produce a large effect because sensitivities of the order of a small number of odorous molecules per receptor cell have been reported at threshold. This large effect must be able to produce an increase in the conductance of a limiting resistance membrane, that is, it must increase the density of charge carriers, or the mobility of the charge carriers in the membrane, to depolarize the membrane (or a limited region of it) This last requirement, when coupled with the threshold sensitivity for smell, implies strongly that an amplification process is needed—the number of charge carriers traversing the membrane must be a large number times the number of adsorbed molecules present in that locality The theory must account for the nature of the different receptor types, and for the fact that a chemical will differentially excite these types, that is, it should allow us to organize the chemicals into different classes by the interaction mechanism It is also obvious that different chemicals have very different thresholds for detection—this, too, must be correlated through the proposed interaction mechanism And, as a final requirement of the theory, fatigue or adaptation, the diminishing of the signal strength with continuous or repeated exposure to high concentrations of certain odorous molecules, should be explicable

---

* Present address Department of Chemistry, University of British Columbia, Vancouver 8, British Columbia, Canada

† Present address USA Garrison, Ft Detrick, Maryland

Earlier theories of olfaction have been reviewed by Moulton and Beidler[1] We should like to present now the outline of a mechanism for olfactory transduction which seems to be consistent with all of the criteria we have mentioned It depends on the formation of a weak bound complex between an adsorbed gas molecule and certain carotenoid pigments Carotenoids, both free and bound to proteins, have been identified in the olfactory mucosa[2-6] This weak bound complex is not well understood, but it is most likely a donor-acceptor complex and we shall call it this Further investigations may modify this identification, but this modification will not alter the theory We have found that these weak bound complexes exert a large controlling effect on the conductivity of these pigments This is the fundamental observation

Carotenoids are semiconductors, both in the glass and crystalline states The electrical properties of β-carotene in particular have been extensively investigated[7] In an earlier investigation it was observed that the semiconductive properties of β-carotene were changed by the adsorption of oxygen molecules on the crystalline surfaces Effects of gas on the conductivity of other organic and inorganic semiconductors have been widely reported Gutmann and Lyons have reviewed this work recently[8] In this particular case, the surface conductivity of the β-carotene was increased by factors of up to 10^3, proportionally to the exponential of the partial pressure of oxygen in the surrounding atmosphere This effect was completely reversed by changing the atmosphere to one of pure nitrogen From the temperature and time dependence of the reversal, it was shown that the binding energy was 0 17 eV It was suggested then that a partial donor–acceptor complex had formed between the adsorbed oxygen and the carotene molecules on the surface of the crystallites This donor–acceptor complex caused a decrease in the activation energy for the thermal generation of charge carriers from 1 52 eV in a vacuum or inert atmosphere to 1 25 eV in the presence of oxygen This decrease in activation energy was sufficient to explain the increased conductivity

More recent investigations have shown that many other gases present in the atmosphere of the chamber can cause increases in current as great as 10^7 times the inert gas value[9,10] In Fig 1 we show, schematically, the apparatus used in these experiments These effects are all (in proper temperature conditions, that is, less than 50° C) reversible with about the same time course as found for oxygen, and suggest similar, if not identical, activation energies for the break-up of the weak bound complexes and subsequent desorption The gases which we have tested for this effect were chosen from three categories—no (or weak) odour, moderate odour and strong odour The results of these tests are shown in Table 1, where we have listed the gas and the increase in current caused by adsorption of this gas on crystallites of β-carotene The inert gases, as well as hydrogen and nitrogen, gave values no different from those obtained in a vacuum, and carbon dioxide, nitrous oxide, butanol and hexanol produced only small increases, less than a factor of 10 We shall discuss the esters later. The gases with moderate odours produced increases in current of a factor of 10^2–10^3, while gases with strong odours produced large increases in current of a factor of 10^5–10^7 With some gases, for example, ammonia and methanol, "puff" experiments can be done by injecting a 1 sec pulse of the gas into a stream of nitrogen and watching the current rise and then decay If β-carotene is only one of the pigments making up the different types of receptor, then it is possible for a gas with a strong odour to be found in the group producing small increases in current if this gas is not of the class to which β-carotene responds We believe this to be the case for the esters as described here If this theory is correct, however, we should not find a gas with no (or weak) odour in the category producing large increases in current This is shown by the results so far Oxygen is the only odourless gas in the group producing moderate increases in current and, indeed, a special case should be made for this gas as it is present in constant quantity in all normal air A detailed description of the experimental conditions is being published[9]

Table 1 CURRENT INCREMENTS IN A β-CAROTENE CELL WITH VARIOUS ADSORBED GASES (NOT CORRECTED FOR EQUAL VAPOUR PRESSURE)

Gas adsorbed	Approximate current increase ($\sigma_{\text{steady state}}/\sigma_{\text{initial}}$)
(1) Nitrogen	1
(2) Hydrogen	1
(3) Argon	1
(4) Helium	1
(5) Nitrous oxide	2
(6) Carbon dioxide	10
(7) Butanol	7
(8) Hexanol	5
(9) Heptanol	5
(10) Octanol	4
(11) Decanol	4
(12) Methyl acetate	10
(13) Ethyl acetate	3
(14) Butyl acetate	3
(15) Pentyl acetate	3
(16) Oxygen	10^2
(17) Isopropanol	10^2
(18) Sulphur dioxide	10^3
(19) Propanol	10^3–10^7 (?)
(20) Acetone	10^4
(21) Nitric oxide	10^4
(22) Ethanol	10^5
(23) Ammonia	10^5
(24) Hydrogen sulphide	10^5
(25) Methanol	10^6
(26) Nitrogen dioxide	10^6

In Fig 2, we have plotted the current rise on a log scale versus the time of flow for a series of alcohol vapours carried by nitrogen gas The rise and decay times are almost totally caused by the flushing time of the chamber containing the β-carotene cell The sizes of the responses are not corrected here for the different vapour pressures of the alcohols (all maintained at a temperature of 15° C) The results, nevertheless, show that the carotene cell responds very differently to the different alcohols With smaller chambers and higher flow rates, the speed of response is very fast In all the cases where large increases in current were found, it was observed that the semiconduction activation energy of the surface currents caused by gas adsorption was lowered enough to account completely for the increase in current

We have investigated this phenomenon in some detail and conclude that the same simple theoretical model proposed for the increase in current in crystalline proteins with hydration[11] is applicable A brief description of this

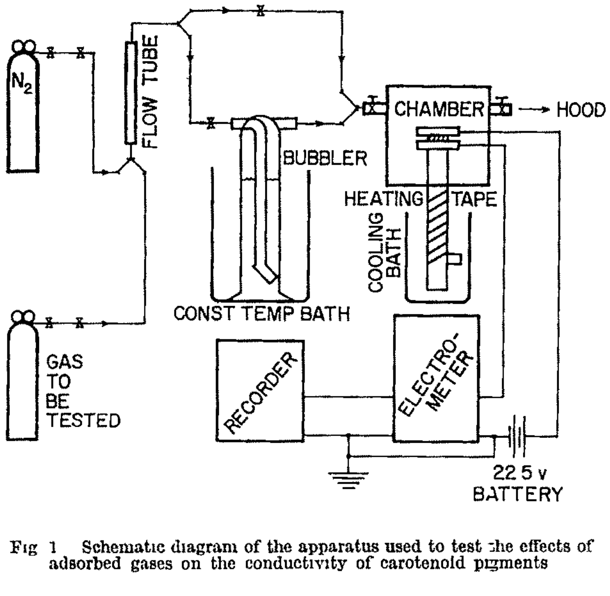

Fig 1 Schematic diagram of the apparatus used to test the effects of adsorbed gases on the conductivity of carotenoid pigments

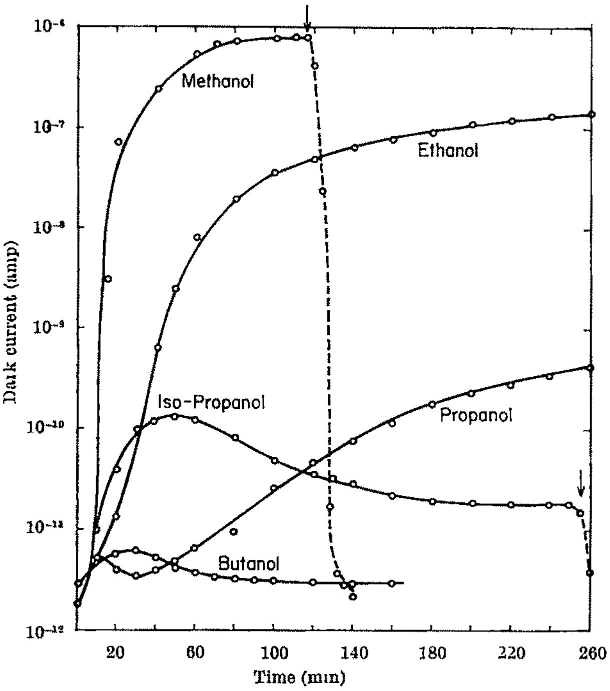

Fig. 2. Time course of the current rise and decay when nitrogen gas is bubbled through various alcohol liquids kept at 15° C and passed through the chamber. Arrows indicate when pure nitrogen alone is flushed through the chamber. Propanol shows a unique slow rise time.

model is essential. Experiments have shown that the conductivity, σ_A, of the carotene-gas complex increases with increasing gas adsorption, m (m = percentage by weight of adsorbed gas), at constant temperature and at low coverage according to the relation

$$\sigma_A = \sigma_v \exp[\alpha m] \qquad (1)$$

where σ_v is the conductivity in a vacuum or an inert atmosphere, and α is a constant for a given system. The temperature dependence of the conductivity of the carotene is that of a semiconductor, and so it is given by the relation

$$\sigma_v(T) = \sigma_0 \exp[-E_v/2kT] \qquad (2)$$

Combining equations (1) and (2) gives the empirical relation

$$\sigma_A(T,m) = \sigma_0 \exp[-E_v/2kT] \quad \exp[\alpha m] = \sigma_0 \exp[-(E_v - \gamma m)/2kT] = \sigma_0 \exp[-E_A/2kT] \qquad (3)$$

where $\gamma = 2kT\alpha$. The activation energy of the complexed crystals, E_A, is equal to $E_v - \gamma m$, and changes continuously with increasing gas adsorption. Measurements of the activation energies with different amounts of adsorbed gases have verified equation (3). We now calculate the energy necessary to separate a charge carrier from one molecule in the medium and place it on another a large distance away (that is, the coulomb interaction is neglected). This is given by

$$E_v = I_g - A_g - \frac{e^2}{R}\left(1 - \frac{1}{K}\right) \qquad (4)$$

where I_g is the gas state ionization energy of the molecule, A_g is the gas state electron affinity, K is the low frequency dielectric constant of the solid, e is the electronic charge, and R is the radius of the polarization cavity field. For the complex, if it is a weak binding type, we can approximately write

$$E_A = I_g - A_g - \frac{e^2}{R}\left(1 - \frac{1}{K'}\right) \qquad (5)$$

where K' is the new dielectric constant and $K' > K$. Eliminating $I_g - A_g$ from equations (4) and (5) results in the following relation

$$E_A = E_v - \frac{e^2}{R}\left(\frac{1}{K} - \frac{1}{K'}\right) \qquad (6)$$

The semiconduction relation is then

$$\sigma_A(T,K') = \sigma_0 \exp[E_v/2kT] \quad \exp[(e^2/2kTR)(1/K - 1/K')] \qquad (7)$$

where the second exponential term is the magnitude of the current increase as a result of the formation of the complex.

We have found for the two gases we have tested—oxygen and methanol—that the dielectric constant of β-carotene does increase when the complex is formed, and by almost exactly the correct amount required to predict the correct activation energies and conductivity increases using equations (6) and (7). Incidentally, this approach is free of any suppositions concerning injected charge carriers or on the nature (electronic versus ionic) or sign of the charge carriers.

It still remains a serious problem to understand why the formation of the weak bound complex changes the dielectric constant. A clue could be obtained from the theory of donor-acceptor interaction, which postulates a partially dative ground state (D^+A^-). This could lead to additional dipole fields. On this basis, we can only tentatively conclude that the weak bound complexes formed between the adsorbed gas and the β-carotene molecules are donor-acceptor complexes. In some other cases (such as the iodine-lipid and dinitrophenol-lipid complexes, see later) this conclusion is strengthened by spectral evidence of a donor-acceptor complex. We have not as yet found any charge transfer bands as evidence of the donor-acceptor complex of gases with β-carotene in the solid state (unpublished work of T. N. Misra and B. Rosenberg).

Differential Sensitivity and Receptor Types

Table 1 shows that the esters, methyl and ethyl acetate, produce less than a factor of 10 increase in the conductivity of the β-carotene cell. This is surprising, for the esters have a low threshold for detectability and, like other very odorous gases, it should have increased the current by a factor of about 10^6. We then measured the current increase in a cell of crystalline powder vitamin A alcohol exposed to these vapours. This chemical is a semiconductor with a low conductivity—on the order of that of β-carotene. The geometry of the conduction cell, as well as all other conditions, was maintained unchanged. The results are shown in Fig. 3. Here the current increase caused by adsorbing methyl acetate on β-carotene and vitamin *A* alcohol is compared. It is obvious that the vitamin *A* alcohol has the expected sensitivity to the esters, while the β-carotene does not.

This one case illustrates the possibility that the different carotenes and haplocarotenes function as the different receptor types, each with its own class of compounds which form the donor-acceptor complexes with it and therefore change the conductivity. Much more work remains to be done to test this crucial hypothesis of the theory and to sort out the respective classes of chemicals reacting with each receptor type. This particular example, however, is clear cut and significant, and serves to indicate the method for these tests. A more complete characterization of the pigments present in the olfactory organ is now necessary.

Fatigue Effects in Semiconduction

A second unexpected result of our experiments is the appearance of a fatigue effect in the conductivity process with certain gases. While the biological processes of fatigue or adaptation in sense organs are complicated by contributions occurring at each stage of the pathway between receptor and consciousness, there should still be fatigue or adaptation effects at the earliest stages. This

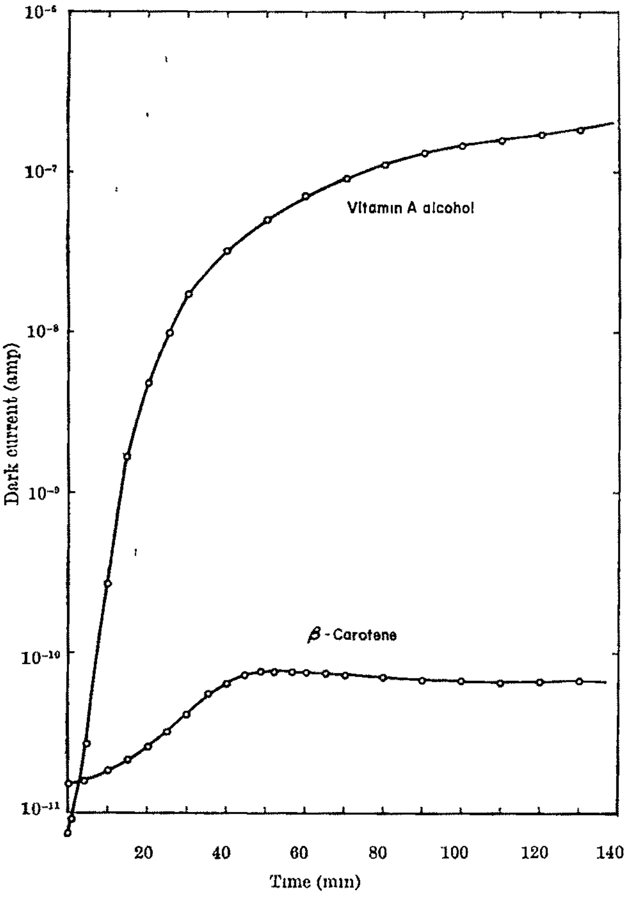

Fig 3 Comparison of the conductivity changes in β-carotene and vitamin A alcohol crystals (both all *trans*) when methyl acetate vapour carried by nitrogen gas is passed through the chamber

certainly holds in the case of the visual receptor, where a contribution to adaptation is known to occur in the receptor cell before the first synaptic connexion The anatomical simplicity of the olfactory system, in which only one synapse occurs in the pathway to the brain, makes a fatigue effect even more imperative at the receptor cell level

In Fig 2, the shape of the current versus time curve for isopropanol differs from the others, for with continuing exposure to the vapours at high concentration (partial pressure = 12 mm of mercury) the current increases to a maximum and then declines This effect is more clearly manifested with ammonia gas adsorbed on a β-carotene cell as shown in Fig 4 Here the current has risen by five orders of magnitude on first being exposed to the gas, and then decreases by three orders of magnitude before reaching a steady state When the gas is removed, by flushing the chamber with nitrogen only, the current returns to its original value This indicates that no marked chemical reaction has occurred between the ammonia gas and the β-carotene (at higher temperatures, however, there is such a permanent change in conductivity attributable to a chemical reaction) If ammonia gas is again passed into the chamber, the current rises again, but by only a factor of 10, indicating that the surface of the β-carotene has changed in some significant way In Fig 5, we show the effect of a number of such reversible flushes, each repetition of which causes a smaller change, until after five repetitions the current rise becomes reproducible and stable

After flushing with nitrogen gas for a few hours, the sensitivity to ammonia returns and the entire process can be repeated In essence, the surface of the β-carotene recovers its sensitivity There are at least two interpretations of this recovery process The first is that it is a result of the process of sublimation of the contaminated surface layers, thus exposing a virgin surface to the next ammonia gas exposure The second is the slow break-up of a more tightly bound complex and subsequent desorption of the ammonia—where the more tightly bound complex occupies the same sites as does the first type of complex but does not affect the conductivity While the sublimation process is attractive in explaining the recovery, it does not provide a basis for explaining the initial fatigue effect The second process can account for both effects Indeed, experimental evidence in favour of this second explanation has already been reported

We have already described the effect of oxygen adsorption on the conductivity of crystalline chlorophylls, *a* and *b*[12] It was shown that oxygen could exist in two states on the chlorophyll crystal surface In the first state, it increased the conductivity (donor–acceptor complex) and was easily desorbed In the second state, it did not affect the conductivity, and was more tightly bound to the surface (Ch^{+}–O_2^{-} ?) Irradiation by light converted the second form to the first form In the dark, the conductivity of crystalline chlorophylls was again higher, and the adsorption of gas was repeated a few times, with diminishing effects, until it almost disappeared A fresh exposure to oxygen would then start the same series of changes again

On the basis of these results, we suggest the following events as determining the fatigue effect and recovery The ammonia gas is adsorbed to a specific site on the crystallite, it forms a donor–acceptor complex with the β-carotene, there is an increase in the effective dielectric

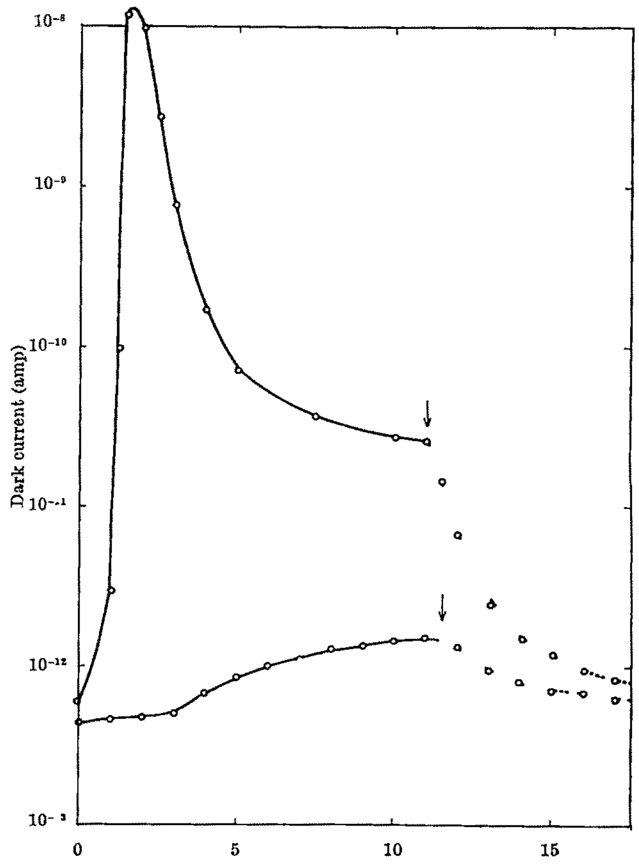

Fig 4 Fatigue effects in the conductivity of β-carotene when exposed to high concentrations of ammonia gas (NH_3 N_2, 1 1) The top curve is the first exposure and removal (arrows indicate the latter), the bottom curve is the second exposure

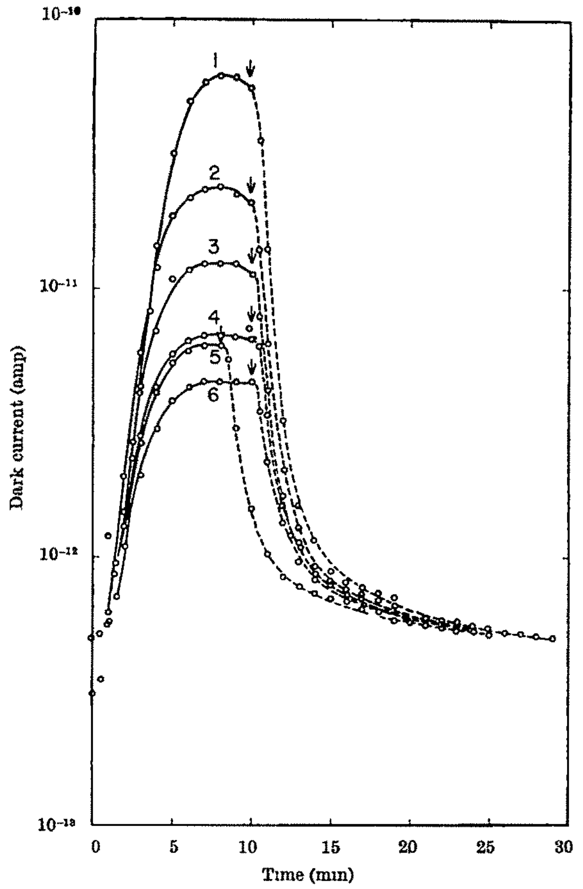

Fig 5 Fatigue effects in the conductivity of β-carotene after partial recovery of sensitivity, when exposed to ammonia as in Fig 4 Each repeat of the exposure and removal of the ammonia gas produces a smaller response until after six exposures the response stabilizes Repeats 7 to 10 (not shown here) are essentially the same as curve 6

constant, the activation energy for thermal charge generation decreases, and the conductivity increases This is state I The donor–acceptor complex converts in an equilibrium process to a more stable form (an ionic complex ?) on the same site which decreases the contribution to the effective dielectric constant, the conductivity decreases to a lower value, the binding energy of the complex is stronger and it therefore does not easily desorb This is state II (We thank L G Augenstein for recalling this two state hypothesis to our attention) When the chamber is flushed with nitrogen, the state I population decreases rapidly to zero and the conductivity returns to the usual nitrogen value The state II population slowly desorbs and/or slowly reverses to the state I type which desorbs, leading eventually to the total loss of the state II population The surface is returned to its initial condition Some more tests of this hypothesis are required and are under way at present in our laboratory The hypothesis is attractive in being able to explain the occurrence of fatigue and the subsequent recovery, and in a manner which agrees with the proposed theory We suggest that this may be at least a part of the fatigue effect in olfaction

Lipid Bilayers

So far, the experimental evidence submitted as the basis of this theory has been obtained on crystalline or glassy powders We do not suggest that such structures as these occur in the receptor membranes A more direct model system for a membrane is the bimolecular lipid films (lipid bilayers)[13] We have investigated such bilayers, using egg lecithin, synthetic lecithin and oxidized cholesterol The conductance of such bilayers increases by 10^5–10^6 when iodine (I_2, 10^{-5} molar) is added to the water electrodes[14] Spectroscopic evidence has been obtained which shows that charge transfer bands occur when iodine and these lipids interact in solution[15], and also that donor–acceptor complexes do form Solid state film experiments agree with these results and also show that the effective dielectric constant of the film increases when iodine vapour is adsorbed Again, these complexes are reversible

The same type of phenomena have therefore been found to occur in a system more like the biological situation In this case, no carotenoid was present in the bilayer, and only iodine and dinitrophenol have been tested so far Nevertheless, two important conclusions can be drawn from this work The first is that an unpigmented membrane may react to the presence of noxious chemicals by the proposed mechanism, and this may account for the response of the trigeminal nerve to higher concentrations of such chemicals The second conclusion is that bilayers incorporating various carotenoid pigments[16] form a simple and more significant model for the further testing of our theory Were it not for this possibility, we would hesitate to add yet another theory to the many already proposed to explain the phenomenon of olfactory transduction

On the basis of the experimental results described here, we propose the following as a possible mechanism for olfactory transduction (1) The pigments in the pigmented olfactory receptors constitute the recepter sites (2) These pigments exist to some degree in the limiting resistance membrane of the receptor cells (3) The odorous molecule when adsorbed on the receptor site forms a weak bound complex (a donor–acceptor complex) with the pigment molecule (4) The conductivity of the membrane increases because of an increase in the equilibrium number of charge carriers resulting from the donor–acceptor complex. (5) This increase in conductance is an amplifying process and leads to the depolarization of the membrane and signal generation (6) The donor–acceptor complexes are weakly coupled (binding energy less than 0 20 eV) and break up, leading to a desorption of the odorous molecule when the partial pressure of such molecules in the ambient atmosphere decreases (7) The nature of the donor–acceptor complex determines the amount of increase in conductance, and therefore the threshold sensitivity to the odorous molecule (8) The odorous molecule may form different strength donor–acceptor complexes with the different pigments of the various receptor types, and the resulting complex of signals defines the odour quality of that molecule (9) Such donor–acceptor complexes may form to a lesser degree between some molecules and the phospholipid constituents of an unpigmented membrane and produce similar, though weaker, signals through the same mechanism

Origin of Nitrate Deposits

by
G G C. CLARIDGE
I B. CAMPBELL
Soil Bureau,
Department of Scientific and Industrial Research,
New Zealand

New evidence from Antarctica supports the idea that nitrate deposits have been accumulated by precipitation from the atmosphere, in the absence of leaching and biological activity

DURING the summer of 1964–65 we surveyed soils in Antarctica at several localities along the western margin of the Ross Sea and Ross Ice Shelf We found that these soils showed many of the features of soils of arid climates, including the accumulation of water-soluble salts In particular, we found that included in these salts were nitrates of sodium and magnesium, together with traces of iodates Nitrate salts were found to be widespread in Antarctica in soils from various parent materials

The salt deposits that reveal most about the origin of the nitrates are those of the valley of the Shackleton Glacier, in the Queen Maud Range (Fig 1), in soils described earlier[1] These salt deposits can be divided into two groups, those of the Roberts Massif at the head of the Shackleton Glacier on the edge of the Polar Plateau, and those about 30 miles down the glacier near its junction with the McGregor Glacier

Roberts Massif is a large nunatak about 50 square miles in area which is encircled by two branches of the Shackleton Glacier and has an altitude of between 7,000 and 10,000 ft At some time in the past, the Polar Plateau was at least 1,000 ft higher than it is now, and covered the whole of the region As the level of the plateau has fallen, the ice retreated uncovering moraine-covered surfaces on which weathering has taken place and primitive soils have formed Each of these soils contains a horizon consisting predominantly of salts at a depth of 2–3 in below the surface The thickness of this horizon increases with the age of the soil, as indicated by weathering and topography, and so the accumulation of the salt is the result of a long-term process and is not some fossil feature The salts consisted of sulphates and nitrates of sodium, calcium and magnesium, together with traces of iodate, no chloride was detected and the ratio of chloride to nitrate was less than 1 15,000 (Table 1) The salt horizons contained minerals such as gypsum thenardite, epsomite, hexahydrite, bloedite, darapskite and soda-nitre

* Not detected by the analytical method used

At the McGregor Glacier junction, where other extensive areas of bare ground occur, the proportion of chloride in the salts was greater, the ratio of chloride to nitrate approaching 1 1 in places (Table 1) In this area, salts do not occur as distinct horizons but are distributed throughout the soil—in places as nodules of salts, but commonly with no salt visible

These two regions differ markedly in climate, which accounts for the difference in composition, amount and distribution of the salts in the soils The Roberts Massif region on the edge of the Polar Plateau is constantly swept by a cold, dry katabatic wind from the south,

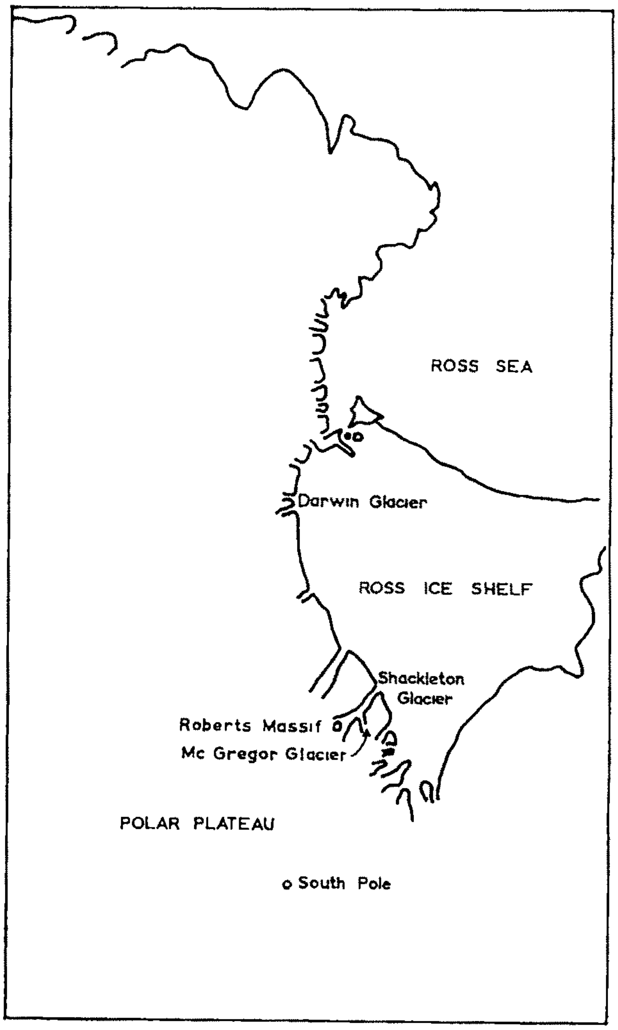

Fig. 1 Map of western margin of the Ross Ice Shelf showing localities of deposits on which nitrate studies were based

precipitation is very low and most of the snow that falls is blown from the Polar Plateau, temperatures are rarely, if ever, above freezing point and little if any melting of the snow takes place, instead the snow either sublimes or is blown away In this region any salts contained within the snow remain behind when it sublimes and may be transported a few inches into the soil by small amounts of moisture which may occasionally be present Consequently, the salts found in these soils should be related to the salt content of Polar Plateau snows

Further down the Shackleton Glacier at the junction with the McGregor Glacier the climate is warmer and precipitation is higher, the snowfalls occurring during periods when warm air masses move in across the Ross Ice Shelf bringing cloudy conditions to the coastal mountains We observed that, during the summer, cloudy conditions and light snow did not reach as far inland as the Roberts Massif, presumably being driven back by the increasing force of the katabatic wind from the south near the edge of the Polar Plateau Conditions in winter are unknown, but the precipitation pattern is expected to be similar

A third region even warmer and more moist than the other two can be defined near the coast and at a low altitude Although we could not examine the coastal region of the Shackleton Glacier Valley, it is thought to be very similar to the coastal portion of the Darwin Glacier Valley, where chlorides make up a greater proportion of the salts, but nitrates and iodates are still present (Table 1) Where temperatures are warm enough and drainage is impeded, salts may accumulate in highly saline ground water or as evaporite deposits around the edges of undrained basins[2]

Any differences in the nature of the salts contained in the soils of these regions should be related to the differences in origin of the precipitation—the Roberts Massif snows coming from the Polar Plateau, and those from areas nearer the coast being derived from local air masses gaining their moisture from the Ross Sea The principal difference is the virtual absence of chloride from salt deposits of the Roberts Massif region and its presence in soils closer to the coast

Wilson and House[3] have shown that snow falling at the South Pole contains small quantities of nitrogen in the form of nitrate Ammonia and organic nitrogen were not detected Small quantities of chloride and a smaller proportion of sulphate were also present, the molar ratio of chlorine to nitrogen being 2 1 The infall of nitrogen was reported to be 5×10^{-8} g/cm^2/yr They suggested that the nitrate was atmospheric nitrogen fixed by auroral processes, and that the chloride and sulphate are ultimately derived from the ocean

A considerable volume of work on the composition of atmospheric precipitation has been published and this has been reviewed by Eriksson[4] Both ammonia and nitrate–nitrogen have been detected in analyses of atmospheric precipitation together with compounds of chlorine, sulphur and iodine Most of these materials are thought to be derived from the sea Wilson[5] has shown that the upper, very thin layer of the ocean is enriched in nitrogenous biological materials which are transferred to the atmosphere during periods of strong winds He suggests that this is the source of the nitrogenous compounds found in the snows of temperate regions Near the oceans, most of the nitrogen is in the form of ammonia or protein compounds, but these are slowly oxidized, probably by ozone produced by the action of ultraviolet light in the upper atmosphere[6] Sulphides are similarly oxidized to sulphates and iodine compounds to iodates Lodge and Pate[7] have shown that the atmosphere over tropical oceans contains ammonia, but that the proportion of nitrogen oxides increases over land masses The proportion of chloride in atmospheric precipitation decreases with increasing distance from the sea, because of the removal of sodium chloride crystals which act as condensation nuclei and are thus precipitated from the atmosphere[8]

We believe that the compounds of nitrogen, sulphur and iodine in tropical and temperate regions are transported to the polar regions by the atmosphere in the course of circulation to maintain the permanent anticyclone induced by the altitude of the Antarctic continent and which is centred over the continent[9] During transport, they are oxidized to nitrates, sulphates and iodates The greater part of these compounds are removed with atmospheric precipitation but, as already explained, chlorides are removed preferentially

The remaining salts are precipitated with snow on the Polar Plateau in the quantities and proportions found by Wilson and House[3], and are transported by wind to areas of bare ground, such as the Roberts Massif, where they accumulate when the snow sublimes or melts and evaporates A further mechanism must be postulated, however, to account for the virtual absence of chloride from the soils of the Roberts Massif and its presence in snow at the South Pole We suggest that, because sodium chloride is more hydroscopic than other salts, it may dissolve and percolate deeper into the general mass of the ice, and that consequently it is progressively reduced in concentration during continual blowing around of drifting snow This can be supported by the fact that Wilson and House[3] report the presence of chloride in snow from a depth of 13 m but not from surface snow at the South Pole

The only other area in the world where nitrates and iodates are widely distributed is northern Chile Many hypotheses on the origin of the Chilean deposits are discussed by Goldschmidt[10], who suggests that, because Chilean nitrate contains approximately 0 2 per cent iodine as iodate, a solution to the problem of origin of these deposits might be found if the presence and state of oxidation of iodine compounds in salt deposits in other parts of the world were studied The proportion of iodate to nitrate in the Antarctic salts is similar to that in the Chilean nitrate deposits (Table 1), consequently, it seems likely that the nitrates and iodates are genetically related and have a similar origin in both the Chilean and Antarctic deposits

The possibility that the nitrates and iodates could have been derived by leaching from sedimentary rocks (as suggested by Johanneson and Gibson[11]) is disproved by their widespread distribution in soils formed from widely different rocks Igneous rocks have been found to contain small amounts of nitrogen[12], but the amount released at the slow rate of weathering prevailing in Antarctica seems to be insufficient to account for the quantities of nitrate present Furthermore, the iodine content of the salts is also left unexplained

A new general theory of the origin of principal nitrate deposits is proposed The atmosphere contains small quantities of nitrogenous material as well as compounds of iodine, sulphur and chlorine derived from the ocean surface in the manner suggested by Wilson[5], and these compounds, in varying proportions and states of oxidation, form part of the precipitation from the atmosphere throughout the world In most parts of the world, the compounds are intercepted by organisms or pass by leaching through the soil and are returned to the sea It is only in the almost complete absence of biological activity and leaching in such places as the Antarctic Continent and the deserts of northern Chile that nitrate salts can accumulate on a large scale

In both these areas, the deposits occur on old surfaces where the salts have been able to accumulate for long periods of time, the age of the Roberts Massif surface is considered to be at least several hundred thousand years[1], as are the surfaces on which nitrates are found in Chile[13]

Similar nitrate deposits might be expected in other parts of the world where conditions are sufficiently arid, however, in most of the world's desert areas they may be removed in drainage waters during the rate periods of torrential rainfall, and may be found in saline lakes and other drainage sinks. Nitrate deposits are in fact also known from the arid areas of California[14] where they seem to be similar to the Chilean deposits, but no other deposits of appreciable size are known except in Antarctica.

We thank the Antarctic Division of the New Zealand DSIR and the US Navy for transport facilities, and Dr A. T Wilson for useful discussion.

Induction of the Primary Immune Response

by

I MACKAY MURRAY

State University of New York,
Downstate Medical Center,
Brooklyn, New York

The cause of the induction of the primary immune response could be the depletion of a specific natural antibody

SERUM opsonins play a part in determining intravascular clearance rates of several types of particles, and it seems that recognition of the surface characteristics of the particle first occurs in the blood plasma of the host[1]. Antibodies, either natural or immune, act as opsonins to influence clearance rates by coating the surface of the particle, making it more liable to phagocytosis. Recognition comes about by the complexing of a specific opsonin with the particle at the moment of its contact with the blood, and this complex is removed from the circulation by the reticulo-endothelial cells, which results in a temporary depletion from the circulation of opsonins specific for that particle[2]. This sequence of events is similar to that which accompanies the intravenous injection of antigenic material, for example, bacterial, in non-immune as well as in immune animals.

The phagocytic cells of the reticulo-endothelial system or macrophages are usually found close to antibody producing cells and seem to be implicated in antibody production. A recent theory holds that the macrophage "processes" the ingested antigen by complexing RNA with the antigenic fragments and this complex is transferred to the precursors of antibody forming cells[3]. The minute amount of antigen which can be detected in antibody producing cells does not seem to supply the instruction necessary to support the high level of antibody synthesis that is usually found. Antigens may induce a primary response by indirectly priming cells genetically endowed with the ability to produce a specific antibody. These pre-formed antibodies would be represented in the body fluids by natural antibodies, that is, antibodies usually found in non-immunized animals. The macrophage, by ingesting the antigen–antibody complex[4], would cause a temporary depletion of the specific antibody in the extracellular fluid, an event which may be a signal to the cells producing that antibody. If the body fluids can recognize antigen—the specific natural antibody—and the macrophage removes it from the body fluids, the natural antibody producing cells bathed by the depleted fluid might recognize the absence of a specific natural antibody. Thus the exchange transfusion of blood previously depleted of natural antibodies against sheep red blood cells initiated a primary immune response in the rat equal to that obtained by the intravenous injection of sheep red blood cells.

Essentially the procedure was to adsorb the donor plasma with washed sheep red blood cells *in vitro*, recombine the adsorbed plasma with the donor blood cells and exchange with the recipient by transfusion.

Male rats of two strains were used, a Lewis inbred strain and a Sprague–Dawley (S–D) strain. Donor animals weighed between 250–300 g and recipients between 150–200 g. The citrate solution, 0.38 molar citric acid, 0.075 molar sodium citrate, 0.064 molar sucrose (ACS), was used in the proportion of 1.5 ml/8.5 ml of blood. ACS donor blood (35 ml) was centrifuged, 1,700*g*, for 40 min and 14 ml of the plasma was removed for adsorption. The remaining supernatant plasma was removed without disturbing the buffy coat and the donor red cell volume was adjusted to 10 ml by aspiration immediately before mixing the adsorbed plasma with the donor cells.

Sheep red blood cells (SRBC) in Alsever's solution were washed three times with 0.15 molar sodium chloride–0.01 molar phosphate buffer, *p*H 7.25 (PBS). The donor plasma was adsorbed by mixing with 1 ml of packed SRBC in plastic centrifuge tubes using siliconized pipettes and left at room temperature for 10 min followed by centrifugation, 300*g*, for 15 min at 10° C. The adsorbed plasma was filtered through a 'Millipore *HA*' membrane, pore size 0.45μ, using slight air pressure. After mixing the adsorbed plasma with the donor cells, the blood was passed through gauze and kept at room temperature for 30 min before transfusion.

The recipient was anaesthetized by intraperitoneal injection of 'Nembutal' and a No. 10 polyethylene catheter was inserted in the femoral vein through which 140 USP units of sodium heparin in 0.7 ml of saline was injected. The femoral artery was then cannulated and the outflow collected in a graduated receptacle. Donor blood was injected through the venous catheter at a rate corresponding to the outflow. The percentage exchange of blood was calculated from the formula of Trossman *et al.*[5] based on normal blood volumes of the rat[6].

Serum agglutinin titres against SRBC were measured on the fifth post-transfusion day. All sera were inactivated at 56° C for 20 min. Doubling dilutions of the antiserum with 2 ml final volumes were set up using 1 per cent normal rat serum in PBS as the diluent. The standard SRBC suspension was prepared by adding one volume of 1 per cent trypsin to nine volumes of an approximately 1 per cent suspension of washed SRBC and agitated for 10 min at 37° C. After a final washing the concentration of the SRBC was adjusted photometrically so that 1 ml of the SRBC suspension in 4 ml of water gave an optical density reading at 520 mμ of 0 30 A sample of the standardized SRBC suspension (0 1 ml) was added to the test system and agitated for 90 min at 37° C After centrifugation at 50g for 5 min the tubes were agitated and the highest serum dilution showing agglutination was recorded as the titre

My primary concern has been that solubilization of the surface antigens of the SRBC might have occurred during the adsorption process, for the 'Millipore' membrane would exclude SRBC stromata Three methods were used to test for soluble antigens in the adsorbed plasma ACS plasma, both SRBC-adsorbed and non-adsorbed, was converted to serum by adding 0 08 ml of a solution containing 0 075 moles of calcium chloride and 0 25 moles of magnesium chloride/ml of plasma The serum was heat-inactivated and used as the diluent for the titration of rat anti-SRBC serum Before the addition of the standard SRBC suspension, the tubes were incubated at 37° C for 60 min and followed by a further incubation for 90 min The agglutinin titre was not decreased by the adsorbed serum diluent Serum prepared from adsorbed plasma was diffused against rabbit anti-SRBC serum by the method of Preer[7] with no band formation Antigens were not detected in the adsorbed plasma by the passive cutaneous anaphylaxis reaction in the rat using rabbit anti-SRBC serum by the method of Ovary[8]

Natural antibodies in rat serum against SRBC can be demonstrated by the more sensitive haemolytic method, not by the agglutination method used here The antigenic effect of transfused SRBC-adsorbed blood was as potent as the intravenous injection of the optimum number of SRBC (Table 1) and the strength of the immune response was not influenced by the source of the donor rat blood Non-adsorbed blood, otherwise similarly prepared and exchanged, had no effect on the agglutinin titre The ineffectiveness of smaller numbers of SRBC to induce a primary immune response suggests that the degree of natural antibody depletion may influence the strength of the immune response Whether the stimulus for inducing the antibody response is the result of the contact of the donor cells with the adsorbed plasma *in vitro* or primarily a host response is not known, and for this reason the buffy coat was kept intact and the proportion of donor cells to plasma held constant. Exchange of volumes less than 50 per cent of the host's total blood volume gave significantly lower titres; however, in the studies reported here, between 75 per cent and 80 per cent of the host's blood was exchanged

Relatively large volumes of SRBC are required to adsorb adequately the natural antibody in rat plasma and multiple adsorptions using aliquots of the adsorbent seem to remove the antibody more effectively than one adsorption using the same total volume of adsorbent (Table 2)

The replacement of natural antibodies in SRBC-adsorbed plasma, before mixing with the donor cells, suppressed the immune response in the transfused recipient (Table 3) The euglobulin fraction containing natural antibodies was prepared from an equivalent volume (14 ml) of normal rat plasma by dialysis against 1/150 molar phosphate buffer, pH 5 8, for 48 h The addition of a similar fraction prepared from plasma previously depleted of the natural antibody against SRBC did not influence the degree of the immune response.

Table 1

No of rats	Donor strain	Recipient strain	Treatment of donor plasma	Reciprocal of titre log 2 (mean)
3	Lewis	Lewis	Non-adsorbed	< 1
3	S–D	Lewis	Non-adsorbed	< 1
3	S–D	S–D	Non-adsorbed	< 1
5	Lewis	Lewis	SRBC adsorbed	10 2
5	S–D	Lewis	SRBC adsorbed	10 8
5	S–D	S–D	SRBC adsorbed	10 4
6	2×10^8 SRBC*	Lewis	—	10 5
8	2×10^8 SRBC	S–D	—	10 0
5	1×10^6 SRBC	S–D	—	2 5

* The intravenous injection of SRBC and agglutinin titres on fifth day

3	SRBC-adsorbed	Euglobulin from SRBC-adsorbed plasma	10 6
3	SRBC-adsorbed	Euglobulin from non-adsorbed plasma	2 3

Natural antibodies of surprising specificity occur in most animal species including man[9] Their origins have been attributed either to multiple environmental stimuli[10] or to the maturation of an immunological apparatus under genetic control[11] My thesis would imply that antibody forming cells are primarily under genetic control although dependent on the constant specific and non-specific challenges encountered in the host environment to express their full potential

There was further evidence of a genetic influence in the distinctive patterns of natural antibody concentrations in each animal species studied[9] Landy[12] has shown individual profiles of natural antibody titres within a species in which constant concentrations of specific natural antibodies are maintained for long periods It is suggested that the concept of homeostatically controlled concentrations of natural antibodies in the body fluids is crucial to an understanding of the sequence of events which follow the introduction of the antigen Temporary imbalance of the homeostatic mechanism resulting from the temporary depletion of the natural antibody induces the primary immune response while prolonged imbalance produces immunological tolerance

While an immune response is developing the circulating antibodies show gradually increasing avidity or affinity for the homologous antigen[13], but the variation in the degrees of avidity does not seem to serve any useful physiological function Antigens introduced into a mixture of the homologous 19S and 7S immune antibodies are preferentially complexed by the 7S antibodies with the likelihood that a similar class preference is exercised in the circulation[14] The relatively large quantities of antigen required for the *in vitro* adsorption of the homologous natural antibodies, despite their low titre in serum, may indicate a still lower degree of avidity The efficiency with which an antigen can preferentially deplete the body fluids of a particular class of antibody would be influenced by the degree of avidity of the antibody and thereby provide the induction stimulus to the cells synthesizing that class of antibody It is therefore proposed that the avidities of antibody are very important in determining the character of the immune response

If the cellular stimulus for the induction of the primary immune response is a demand for the replacement of a specific antibody, those cells phenotypically restricted to its production would, by the process of cell division and differentiation, provide antibodies of a similar specificity although not necessarily having the same physical characteristics In presenting a possible sequence of cellular events using the proposed stimulus for immunogenical induction, other significant findings[15–18] seem to be particularly pertinent

The small mobile lymphocyte seems to be the most likely source of natural antibodies and thus implicated in the first phase of the primary immune response[15] The feedback mechanisms by which these cells maintain homeostatic concentrations of natural antibodies in the blood and tissue fluids are unknown although circulating concentrations of a specific natural antibody were apparently independent of the number of cells producing that antibody[19] After contact of the antigen with the body fluids and the removal of the antigen–natural antibody complex by the macrophage, depletion of that specific natural antibody from the extracellular fluid may impose a sudden demand for replacement on those lymphocytes phenotypically restricted to that particular pattern of antibody synthesis Cytoplasmic budding or shedding of the lymphocytes may replace the extracellular antibody to concentrations greater than the homeostatically controlled one, providing the stimulus for replication and further differentiation of that cell clone

What are the factors which might influence the cell clone synthesizing the natural antibody to replicate and transform into a more efficient antibody producing cell ? Would the sudden cessation of demand for the antibody from a cell synthesizing it at increased rates result in a higher energy potential in that cell ? Perhaps the concept of a higher energy potential can be translated as the accumulation of those basic building blocks common to both DNA and RNA-protein synthesis Lack of cytoplasmic competition may permit, for example, the sharp rise in the pool size of amino-acids in the nucleus which precedes DNA synthesis[20] As a corollary, would the continuing increased demand for RNA-protein synthesis during antibody production result in the inhibition of lymphocytic replication and differentiation ?

The experimental evidence would implicate the blast cell as the successor to the small lymphocyte[15] Subject to the same homeostatic mechanisms as the small lymphocyte and stimulated by the antigen-induced depletion of its product, 19*S* immune antibody, the blast cell, unlike the lymphocyte, is not usually found in the circulation The attribute of "immunological memory" has been bestowed on the blast cell rather than the small lymphocyte, but the difference may be qualitative, for, if the strength of immunological memory of the antibody producing cell is determined by the avidity of its product and thus the efficiency with which the antigen can deplete the body fluids, the blast cell would have preference over the small lymphocyte Cessation of demand for the 19*S* immune antibodies may provide the stimulus for blast cell replication and transformation to the plasmocyte which is capable of synthesizing 7*S* antibodies of the highest avidity Circulating concentrations of 7*S* antibody do not seem to be under homeostatic control, for depletion of the antibody is not followed by increased synthesis nor does the mature plasma cell show mitotic activity

A potential role of natural antibodies in the induction of the primary immune response has been postulated by Jerne[21], Talmage[22], Boyden[23] and Landy[12] The mechanism by which natural antibodies exert their directive influence on antibody production has been attributed either to self-replication of antibodies[21] or to their cytophilic properties enabling the potential antibody forming cell to receive the antigenic stimulus[23]

Burnet[24] has pointed out that the mechanism by which the immune system recognizes foreign material is a crucial one in understanding antibody production If depletion of specific antibody from the body fluids is the common immunogenic stimulus, it is tempting to consider the following previously inexplicable findings with regard to antibody production the inhibition of antigen induced antibody production in infants with high circulating titres of maternal antibody, the failure to achieve an antibody response when antigen–antibody complexes are injected or the "blanketing effect" when the second antigen is given during the height of the primary immune response, the practice of coating particles with soluble antigens, thereby increasing the surface area of the antigen and permitting larger quantities of antibodies to be complexed

The enhancement of antibody production has been shown to be a non-specific effect[25] Endotoxin releases natural antibodies non-specifically without obvious injury to the antibody producing cells resulting in a five-fold increase in the bactericidal titre of the host serum[19]. The increased titres of circulating antibody were followed by the replication of the antibody producing cells With homeostatic concentrations of natural antibody in the extracellular fluid more than satisfied, could the cytoplasmic events in the cell now modulate activities in its nucleus ? The apparent synergism between the endotoxin-induced cellular depletion of antibody and the antigen-induced depletion of the homologous antibody from body fluids seem to give some understanding of the mechanisms by which adjuvants enhance antibody production

Perhaps the most intriguing relationships exist between immunological tolerance to foreign antigens and the apparent non-recognition of auto-antigens If excess antigen remains in contact with the body fluids for prolonged periods because of a relative deficiency in phagocytosis-promoting antibody, would the homologous antibody forming cells, in attempting to re-establish homeostasis, repress replication and transformation into cells capable of producing larger quantities of more cytotoxic antibodies ? Antibody producing cells in rats made tolerant to SRBC did not respond to repeated SRBC antigenic stimuli by replication although they were capable of producing the homologous antibody[26] There seems to be little reason to advance a different mechanism for the recognition and removal of auto-antigens resulting from the constant breakdown of the host's cellular elements In a situation where there is a continuous uniform release of either auto-antigens or foreign antigens from a successful cellular transplant at birth, replication of the homologous antibody forming cells may be inhibited by similar mechanisms The elucidation of those events occurring in the cytoplasm of the cell and their modulating effect on nuclear events may provide a vital link in understanding the mechanisms which control antibody production

While the hypothesis of specific antibody depletion as an inducer of the immune response seems to offer plausible explanations for some aspects of antibody production, it does, however, provide a ready means for its testing

I thank D Lochansky for technical assistance

Half Life of the Neutron and Cosmological Helium Production

I WISH to point out a cosmological consequence of the recent reduction in the experimental half life of the free neutron, if this is confirmed

Since the measurements of Sosnovsky *et al*[1], the best value for the neutron half life has been 11 7 min Recently, a new measurement by Christensen *et al*[2] has given the significantly lower value of 10 8 min Although there may be further measurements before this result is accepted, it had earlier been pointed out by Blin-Stoyle and Tint[3] that there were theoretical reasons for believing that the value of 11 7 min was too large

In the homogeneous isotropic Friedmann universe the amount of helium produced in the early stages is chiefly governed by the relative densities of protons and neutrons when nuclear reactions occur, essentially all of the neutrons and an equivalent number of protons combine to form deuterium and, subsequently, helium At very high temperatures the number densities of protons, n_p, and neutrons, n_n, are related by the formula

$$\frac{n_n}{n_p} = \exp\left(-2\ 54\ m_e c^2/kT\right) \qquad (1)$$

As the temperature drops, the reactions changing protons into neutrons and vice versa

$$\begin{aligned} n + e^+ &\rightleftarrows p + \bar{\nu} \\ p + e^- &\rightleftarrows n + \nu \end{aligned} \qquad (2)$$

are no longer rapid enough to maintain thermal equilibrium and the neutron number remains larger than that given by equation (1) The reduction of the neutron half life implies a corresponding increase in the cross-sections for reactions (2) so that the neutron number remains closer to that predicted by thermal equilibrium There are fewer neutrons when helium production occurs, so the amount of helium produced is reduced

A recent calculation of the helium production in the early stages of a Friedmann universe by Wagoner, Fowler and Hoyle[4] gives a helium production of between 25 per cent and 30 per cent by mass for plausible values of the present mean density of the universe, if it is assumed that the conventional interpretation of the 3° K black-body background radiation is correct This compares with abundances in the same range which have been observed in a variety of objects[5] It seems from an approximate calculation that, if the new value of the neutron half life is accepted, the numerical values of Wagoner *et al* should be reduced to about 23 per cent and 27 5 per cent Although this reduction is itself not very great and is probably within other errors of theory and observation, it is in the correct direction if the cosmological theory is to be correct It is well known that helium can be produced astrophysically but there is at present no belief that large scale destruction of helium has occurred in the universe. Thus all observed helium abundances should exceed that produced cosmologically The reduction in the predicted cosmological helium abundance might therefore prove significant in a detailed comparison between theory and observation

Small Scale Distribution of Interstellar Absorption

A SURVEY programme to take Hα photographs of galactic emission nebulae has been in progress since October 1966 at the Tokyo Astronomical Observatory using the 50 cm Schmidt telescope at the Dodaira Station[1] A combination of Eastman Kodak 103*a-E* plate and Hoya colour glass *R*64 5 mm thick are being used The combination gives a pass-band about 300 Å wide centred at λ6563 Å, and provides Hα pictures of emission nebulae after subtraction of other nebular radiations contained within the passband Each plate is carefully calibrated by means of a tube sensitometer, the absolute brightness scale is obtained by measuring the brightness of selected star images

Seven galactic H II regions, *IC*1795, *IC*1805, *M*20, *M*8, *M*16, *M*17 and *NGC*7000 region, have been analysed so far The photographs are converted to isophotal contour maps using the iso-densitometer of the Tokyo Astronomical Observatory

Comparison of these contour maps of H II regions with those of microwave radio emission is of interest if the mechanisms of both types of radiation are known Both maps represent the emission measure, but the former includes interstellar absorption by solid grains. The comparison thus enables us to make a map of the interstellar absorption by assuming that both radiations are thermal

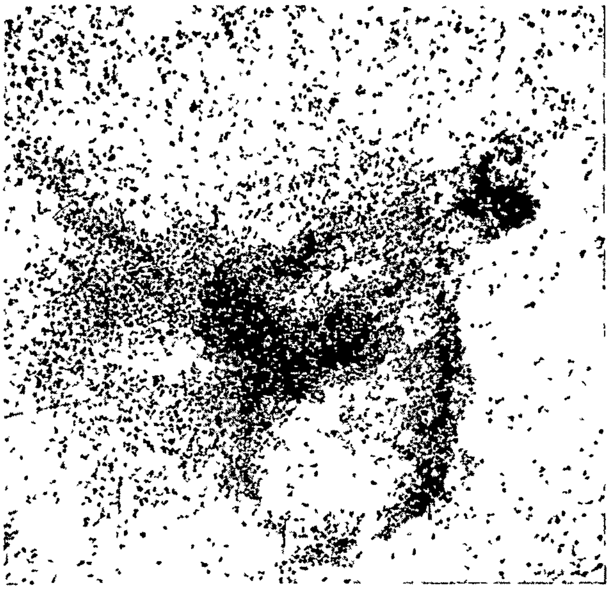

Fig 1 Hα photograph (Kodak 103*a-E* with Hoya *R*64 5 mm) of *IC*1795 (upper right of *IC*1805) and *IC*1805 taken with 50/65 cm F 2 0 Schmidt telescope of Dodaira Station, Tokyo Astronomical Observatory (Plate *SB*161 exposed for 60 min on October 7, 1966)

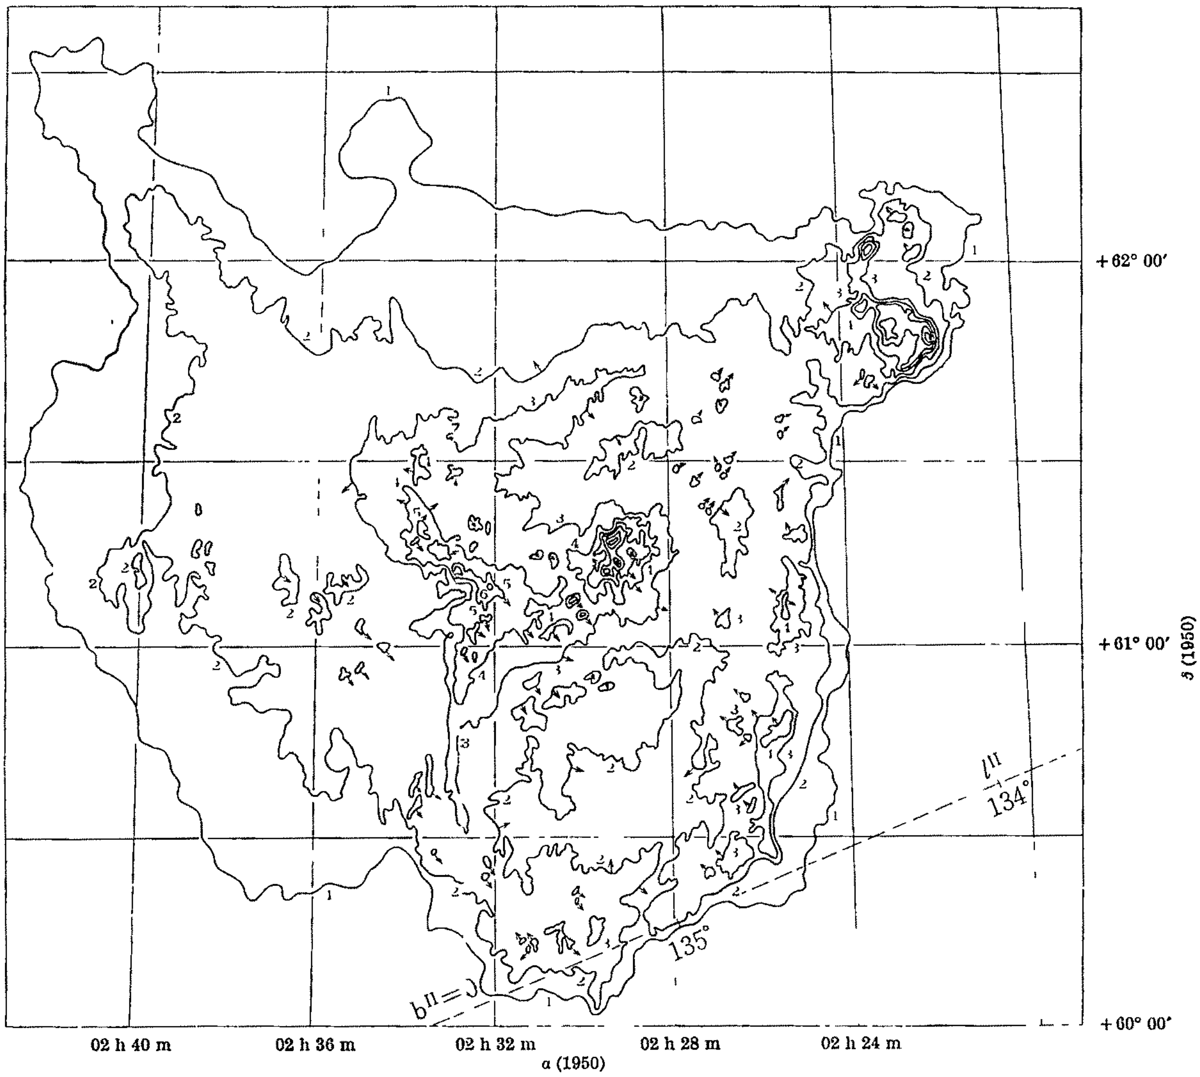

Fig 2 Hα contour map of *IC*1795 = *W*3 and *IC*1805 = *W*4 after Ishida and Ohashi[1]

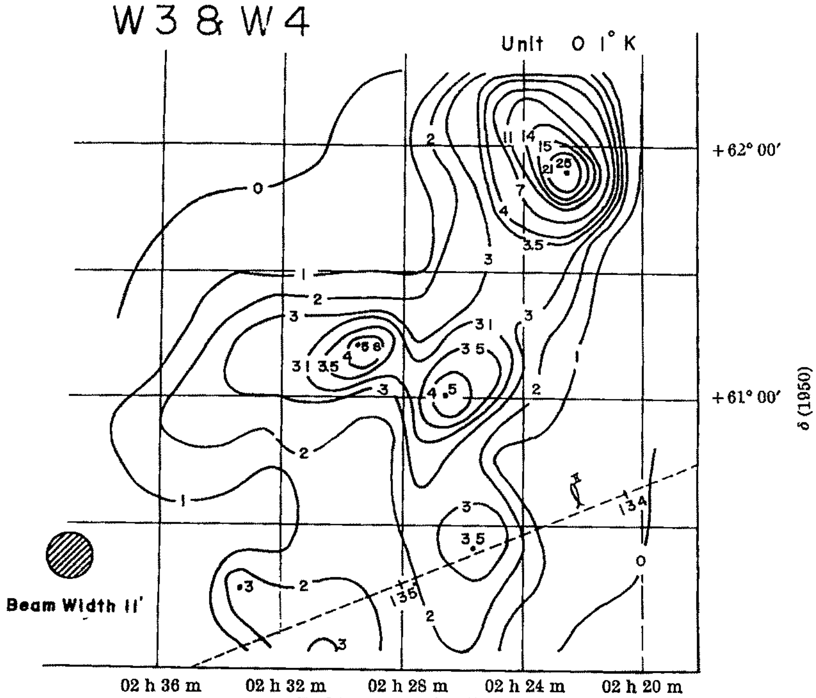

Fig 3 Microwave radio emission map of *IC*1795 = *W*3 and *IC*1805 = *W*4 at 4,170 MHz after Akabane *et al* [2]

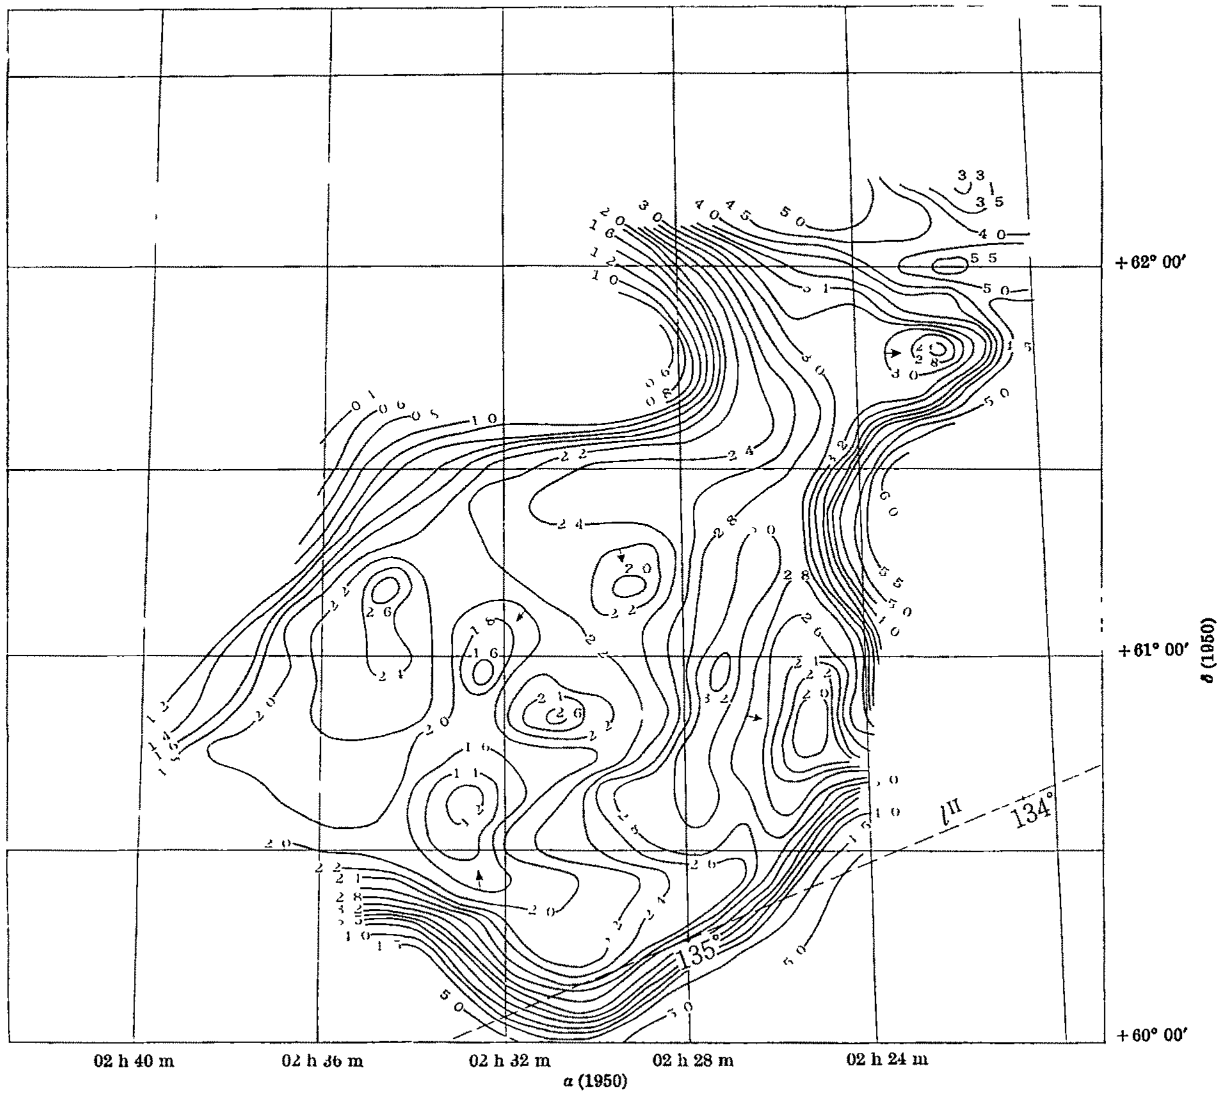

Fig 4 Interstellar absorption map in magnitude units of *IC*1795 = *W*3 and *IC*1805 = *W*4 at λ6563 Å

Figs 1–4 show a comparison for a complex region near the galactic equator (l^{II} is about 134 degrees) Fig 1 is a photograph in Hα light, Figs 2 and 3 are the contour maps in Hα and in microwave radio emission at 4,170 MHz (ref 2), and Fig 4 shows the surface distribution of interstellar absorption over the region The two emission nebulae in the field are *IC*1795 and *IC*1805 (*W*3 and *W*4, respectively, as radio sources)

Small scale structure of absorption is clearly seen in Fig 4 as well as the general tendency towards heavier absorption in lower galactic latitude[3] The absorption obtained is chiefly that within the H II region, but also includes a contribution from the space between the Earth and the H II region. In any case, this is an independent method of obtaining a map of interstellar absorption Interstellar absorption is currently obtained by stellar photometry The observational data, however, are not an absorption value but a colour excess, and the ratio of space absorption to colour excess is still not well known The technique presented here is one of the methods for deriving an absolute value of absorption and it will help to clarify the role of the interstellar dust grains in the H II regions

Production of OH Molecules in Interstellar Shock Waves

MEASUREMENTS made recently at Berkeley have shown that there is interstellar OH absorption in most low latitude radio sources[1] Most indications are that the excitation, unlike that in the intensely emitting regions[2], is fairly normal, and that the state temperature is $T < 10°$ K If it is assumed that $T = 3°$ K (a minimum value, from the cosmic microwave background), the median value of OH/H is about 4×10^{-8} in sources in which both OH and H lines can be measured This ratio, which corresponds to OH/O $\sim 6 \times 10^{-5}$, is not far from that of CH and CH^{+}, seen optically An attempt by Bates and Spitzer to explain the abundance of CH by two body radiative association[3] failed by more than three orders of magnitude This led Stecher and Williams[4] to propose that chemical exchange reactions on grains of the form $GX + Y \rightarrow G + XY$ (where $X =$ H, $Y =$ O for OH) could operate in the heated regions behind interstellar shock fronts They calculated that $OH/H = 3\times10^{-9}$ after a shock passes. Photodissociation ($\tau = 10^4$ yr) between shock passages ($T = 10^7$ yr) reduces OH/H to an average value of 3×10^{-12}, which is four orders of magnitude too low According to Carroll and Salpeter[5], the chemical exchange reaction $O + H_2 \rightarrow OH + H$ produces comparable amounts of OH if $H_2/H \sim 10^{-4}$ According to Stecher and Williams[6], however, H_2/H is kept to the extremely low value of 10^{-7} by photodissociation of H_2

We have calculated the OH production caused by preassociation, as suggested by Solomon[7],

$$O + H \rightarrow OH, K_1 = 3\times10^{-16}\exp(-3,700/T)\ \mathrm{cm^3\ sec^{-1}} \quad (1)$$

where $K_1 = n(OH)/n(O)n(H)$ Obviously this reaction proceeds even if H_2 is absent, but, like the reactions involving H_2 and grains, it requires the high temperatures present behind a shock wave The primary destruction mechanism is[5]

$$OH + H \rightarrow H_2 + O, K_2 = 9\times10^{-12}\exp(-3,709/T) \quad (2)$$

Starting with no molecules, reaction (1) builds up OH behind the shock front, while reaction (2) converts some of these molecules to H_2 The inverse of reaction (2),

$$O + H_2 \rightarrow OH + H, K_3 = 2\times10^{-11}\exp(-4,630/T) \quad (3)$$

and the low-temperature reaction,

$$OH + O \rightarrow O_2 + H \rightarrow 2O + H, K_4 = 1\times10^{-10}\exp(-600/T) \quad (4)$$

were also included, we assumed that O_2 is photo-dissociated immediately The reaction $OH + H_2 \rightarrow H_2O + H$ was neglected because it becomes comparable with reaction (2) only when H_2/H approaches 10 per cent

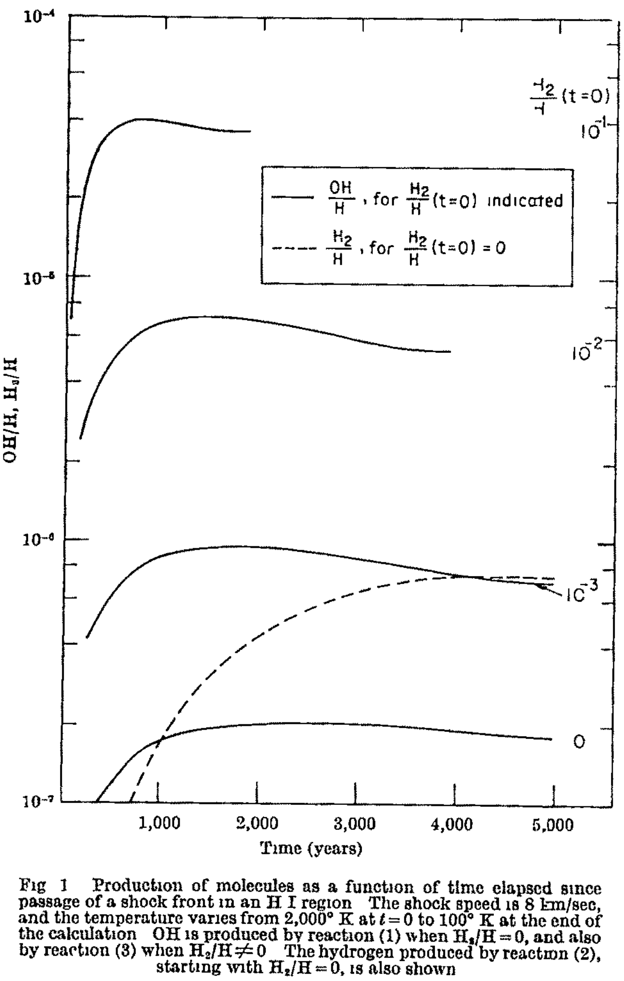

Fig 1 Production of molecules as a function of time elapsed since passage of a shock front in an H I region The shock speed is 8 km/sec, and the temperature varies from 2,000° K at $t = 0$ to 100° K at the end of the calculation OH is produced by reaction (1) when $H_2/H = 0$, and also by reaction (3) when $H_2/H \neq 0$ The hydrogen produced by reaction (2), starting with $H_2/H = 0$, is also shown

Both Stecher and Williams[4] and Carroll and Salpeter[5] used estimated postshock temperature density profiles We used a grid of profiles depending on mach number, initial H_2 abundance and preshock magnetic field strength calculated by Field, Rather, Aannestad and Orszag[8]. Their calculations, for preshock densities $n(H) = 10\ \mathrm{cm^{-3}}$ and $n(O) = 6\ 8\times10^{-3}\ \mathrm{cm^{-3}}$, show that the cooling time ($\sim 10^4$ yr) is reduced from previously accepted values because of frequent inelastic OH collisions with subsequent 63μ radiation. The short cooling time tends to limit molecule production, although it is somewhat compensated by increased densities far behind the shock

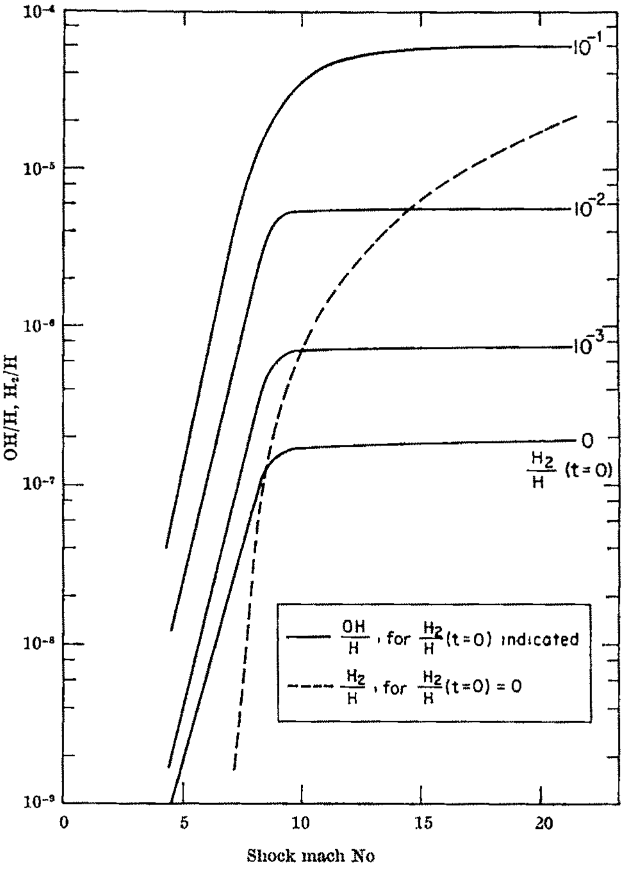

Fig 2 The final molecular abundances after shock passage as a function of mach number (= speed/0 8 km/sec) Significant contribution by reaction (3) requires $H_2/H > 10^{-3}$

Fig 1 shows the OH production for a mach 10 (8 km/sec) shock; the abscissa represents time elapsed since shock passage The calculations are terminated when the material behind the shock has returned to its preshock temperature, assumed to be 100° K For $H_2/H = 0$, equilibrium between reactions (1) and (2) is rapidly attained behind the shock, at $OH/H = 2\times10^{-7}$, independent of temperature Reaction (2) produces some H_2 as shown, but the amount is so small that reaction (3) and the reaction $OH + H_2 \rightarrow H_2O + H$ are safely neglected

Although at present it seems likely that the interstellar hydrogen abundance is very low[6], calculations were made for $H_2/H = 10^{-3}$, 10^{-2} and 10^{-1} to assess the importance of reaction (3) Photodissociation of H_2 was ignored

As expected, far more OH is produced by this exchange reaction. (The value for $H_2/H = 10^{-1}$ is an overestimate because of the neglect of $OH + H_2 \rightarrow H_2O + H$.) Our results agree roughly with those of Carroll and Salpeter, based on estimated cooling curves. The decrease at the end of the curves in Fig. 1 is produced by reaction (4), the only operative in the cooler regions far behind the shock. Fig. 2 demonstrates that reactions (1) and (3) require at least mach 10 shocks to be effective. Lower shock speeds do not result in sufficient temperatures, while higher speeds do not significantly increase molecule production further. In every case, the production of hydrogen is very small. A magnetic field changes the cooling times somewhat, and thus the molecular production. The minimum value achieved, $OH/H = 2 \times 10^{-7}$ when $H_2/H = 0$, is affected only in that larger fields require larger mach numbers for reactions (1) and (2) to come into equilibrium. The minimum effective mach number ranges from 10 for $B = 0$ to 17 for $B = 10^{-5}$ gauss.

If, with Stecher and Williams[6], we set $H_2/H = 0$, the relevant OH/H from reaction (1) is 2×10^{-7} for shocks of mach 10 or more. This is about two orders of magnitude greater than production by chemical exchange reactions on grains (except near hot stars where radiation pressure accelerates the grains through the gas, increasing the OH production[4]). The postshock value of OH/H is reduced by reaction (4) and by photodissociation, for which the combined lifetime is τ. At time t after shock passage, the ratio has dropped by the factor $e^{-t/\tau}$. When averaged for many shock passages (for which the mean interval is T), the reduction factor is τ/T. T is 6×10^6 yr (ref. 9) and τ (photodissociation) from the f-values of ref. 7 and the standard interstellar radiation field is 6,000 yr (ref. 10). Because this is smaller than that for reaction (4), the latter may be neglected. The reduction factor is therefore 10^{-3}, giving a mean value $OH/H = 2 \times 10^{-10}$, about 100 times the amount caused by grains[4]. It is still, however, 200 times smaller than the observed value, so that reaction (1) behind shocks cannot be solely responsible for the observed OH.

If hydrogen is present, Fig. 2 indicates that the factor of 100 can be recovered only if $H_2/H > 1$ per cent. This is much too high for the mean value of this quantity according to ref. 6. The possibility arises, however, that, in the immediate vicinity of shock fronts, production of hydrogen on grains is so rapid that a considerable abundance of hydrogen builds up. Although Stecher and Williams[6] estimate that H_2/H attains only the value 4×10^{-5} behind shocks, this depends on the details of the postshock cooling. We hope to check this in future calculations.

PLANETARY SCIENCE

Fractionation of Iron in the Solar System

BANERJEE[1] has argued against the influence of ferromagnetism on the aggregation of particulate matter in a theory of Harris and myself[2] on chemical fractionation within the solar system.

His objection is based on one of the more unsatisfactory parts of magnetic theory—the prediction of spin structure. I quote a reference[3] he used (page 367). "Some calculations on small multidomain particles have been made but it is fair to say that to date such particles are not understood" (see also ref. 4, chapter 8). Calculations of the likely magnetization of any system are usually hampered by at least the following uncertainties: (*a*) proper enumeration and comparison of all the possible spin configurations, and (*b*) the occurrence of metastable spin configurations.

Assuming that the exact shape of particles formed in the conditions envisaged in the solar nebula is known, the difficulty of satisfying (*a*) is especially great near the Curie point. The simplified enumeration achieved by assuming a domain structure breaks down because of the extremely small crystalline anisotropy constants in the vicinity of the macroscopic Curie point. For the very slowly cooling particles in the completely thermalized environment postulated in the fractionation theory, metastable spin configurations become a real possibility for any particles much larger than the superparamagnetic size limit.

Thus I am surprised at the faith Banerjee has in his method of multidomain calculation and in the significance of his numerical results for the theory[2]. If the validity of his method is accepted, a trivial adjustment to the theory would remove the numerical discrepancy. It would be wrong, however, to conceal the ignorance that surrounds the magnetization of small particles and therefore the effectiveness of ferromagnetism in enhancing collision rates of ferromagnetic particles. In the conditions envisaged, the ratio of collision cross-section to optical cross-section of ferromagnetic particles probably rises from unity as the size exceeds the superparamagnetic limit, could reach very large values and probably declines towards unity for particles greater than 10^{-4}–10^{-3} cm. This size range probably includes a significant fraction of the particle size distribution of the primary condensate[2].

Fortunately, it is not necessary to take refuge in such ignorance. It was pointed out[2] that without long range ferromagnetic attraction, the binary collision rate of iron particles, if they averaged 10^{-4} cm in size, was of the order 1 per year. It would therefore still be possible for large aggregates to be built up. It seems probable that short range ferromagnetic interactions would create a thermally stable bond between any colliding iron particles of greater than superparamagnetic size. With no mechanism of comparable bonding efficiency between non-ferromagnetic particles a size difference of iron and non-metallic particle aggregates would occur. This is the essential step in the theory[2].

Lake Lappajarvi, Central Finland: a Possible Meteorite Impact Structure

LAKE LAPPAJARVI (lat 63° 10′ N, long 23° 40′ E) is situated about 60 km east of Vaasa about 200 km north-north-west of Helsinki (Fig 1) The depression in which the lake is located is largely filled by deposits from the last glaciation

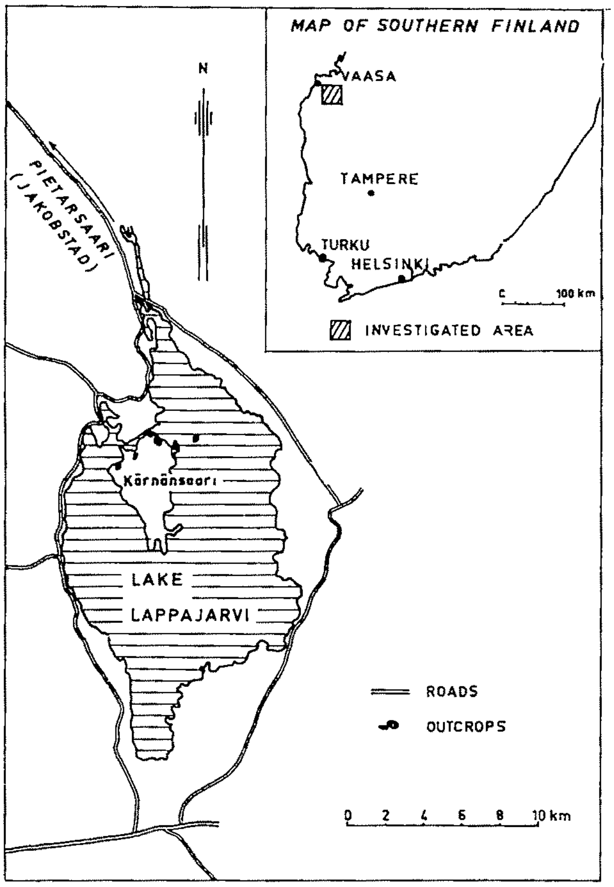

Fig 1 Map of Lake Lappajarvi and surroundings.

Holmberg described a peculiar rock on the island of Karna in Lake Lappajarvi as early as 1858 (ref. 1) The rock type was called karnaite Outcrops have been found on the islands of Karnansaari and Vartijasaari in the northern part of the lake and in boulders along the southern shore-line No karnaite in outcrops or as blocks is known along the northernmost shores[2] The bedrock around the lake is Archaeic and consists of gneisses and granites The boulders which are found to the south of the lake are thought to come from a neck of a volcano, the upper part of which has disappeared[3] Its age is probably post-Archaean but pre-Quaternary[4] The idea that the karnaite boulders emerge from Lake Lappajarvi has been further strengthened by studies of the distribution pattern of the boulders found south of the lake[5,6] The idea of a volcanic origin for the Lappajarvi structure is maintained in the most recent papers and books on the geology of Finland[7] There is, however, another possible interpretation of this structure The karnaite boulders are similar in appearance to corresponding samples from the Ries Basin in Germany and from Lake Mien in Sweden These structures have been interpreted as the result of the impact of meteorites[8,9]

Quartz in bedrock affected by shock waves from meteorite impacts will be deformed and give quartz deformation lamellae with definite characteristics[10] These lamellae follow certain crystallographic planes, for example, (0001), $(10\bar{1}3)$ and $(01\bar{1}3)$, $(10\bar{1}1)$ and $(01\bar{1}1)$, $(10\bar{1}2)$ and $(01\bar{1}2)$, the planes $(10\bar{1}3)$ and $(01\bar{1}3)$ being most common The lamellae are also closely spaced (5 to 30μ apart) and form parallel planar features which do not transgress grain boundaries These lamellae have been found in material from the Ries Basin and from Lake Mien[10] Such lamellae have also been reported from other circular structures such as the Holleford Crater in Canada, the Meteor Crater in Arizona and the Wabar Crater in Arabia[11,12]

Thin sections have been made from fragments of Archaean bedrocks in karnaite found as boulders along the southern shoreline of Lake Lappajarvi These have been studied under the microscope on a universal stage The quartz grains have the same appearance as those described from the Ries Basin, Lake Mien and other similar structures The following crystallographic planes of the lamellae have been measured (thirty-six measurements on sixteen grains) $(10\bar{1}3)$ or $(01\bar{1}3)$, $(10\bar{1}2)$ or $(01\bar{1}2)$, $(21\bar{3}1)$ or $(12\bar{3}1)$, and $(10\bar{1}1)$ or $(01\bar{1}1)$ The direction $(10\bar{1}3)$ or $(01\bar{1}3)$ is the most common, as von Engelhardt *et al* found in the Ries Basin and in Lake Mien[10] These measurements seem to support strongly the interpretation of the Lappajarvi structure as the result of meteorite impact The size of the structure is not exactly known but must be of the order 5–6 km

Radiative Association : Possible Important Loss Process for Metallic Ions in the Ionosphere

THE maximum lifetime of a metallic ion, M^+, in the upper atmosphere is believed to be limited by radiative recombination, $M^+ + e \rightarrow M + h\nu$ The rate coefficient, γ_r, for this process is about (ref 1) 3×10^{-12} cm^3 sec^{-1} at 300° K

Radiative recombination should be contrasted with the loss of atomic ions through the radiative association processes

$$M^+ + O \rightarrow MO^+ + h\nu$$

$$M^+ + O_2 \rightarrow MO_2^+ + h\nu$$

Atomic nitrogen densities are too low at these altitudes for $M^+ + N \rightarrow MN^+ + h\nu$ to be important The ion XN_2^+, if not unstable, is much less likely to be formed than XO^+ or XO_2^+

Radiative association is quickly followed by dissociative recombination, with a rate coefficient of the order 3×10^{-7} cm^3 sec^{-1} Thus radiative association is the rate limiting step in the neutralization of metallic ions, $M^+ \rightarrow MX^+ (MX_2^+) \rightarrow$ neutrals

The loss rate for each metallic ion caused by radiative recombination, $\gamma_r[e]$, is compared in Table 1 with the radiative association loss rates $\gamma[O]$ and $\gamma[O_2]$ at altitudes of interest for the ions of sodium, calcium, magnesium, potassium, silicon, iron, aluminium and nickel The loss

Table 1 LOSS RATES FOR METALLIC IONS BY VARIOUS PROCESSES

Altitude	$3\times10^{-12}[e]$	$10^{-17}[O]$	$10^{-17}[O_2]$	$10^{-30}[O_2]^2$	$10^{-30}[O]\,[O_2]$
110 km	$4\ 5\times10^{-7}$ sec^{-1}	$2\ 0\times10^{-6}$ sec^{-1}	$3\ 5\times10^{-6}$ sec^{-1}	$1\ 2\times10^{-7}$ sec^{-1}	$7\ 0\times10^{-8}$ sec^{-1}
100 km	$1\ 5\times10^{-7}$ sec^{-1}	$5\ 0\times10^{-6}$ sec^{-1}	$2\ 0\times10^{-}$[illegible] sec^{-1}	$4\ 0\times10^{-6}$ sec^{-1}	$1\ 0\times10^{-6}$ sec^{-1}
90 km	$3\ 0\times10^{-8}$ sec^{-1}	$1\ 2\times10^{-6}$ sec^{-1}	$1\ 3\times10^{-4}$ sec^{-1}	$1\ 7\times10^{-4}$ sec^{-1}	$1\ 6\times10^{-6}$ sec^{-1}

rates $\beta[O_2]^2$ and $\beta[O]\,[O_2]^2$ are also indicated for the three body processes $M^+ + O_2 + O_2 \rightarrow MO_2^+ + O_2$ and $M^+ + O + O_2 \rightarrow MO^+ + O_2$, respectively The latter reaction may rather proceed as $M^+ + O + O_2 \rightarrow MO_2^+ + O$ The third body could be N_2

The value of 10^{-17} cm^3 sec^{-1} chosen for γ is not inappropriate Bates[2] calculated rates for radiative association of certain atomic species with rate coefficients roughly in the range $10^{-17\pm1}$ cm^3 sec^{-1} A rate coefficient of 10^{-30} cm^6 sec^{-1} is reasonable for a three body ion neutral attachment process Neutral number densities [O] and [O$_2$] are from CIRA 1965 while the [e] values are typical for daytime

Because sporadic *E* may attain an electron density of 10^6 cm^{-3}, radiative recombination may well be the dominant loss process leading to the neutralization of metallic ions near 110 km and above The altitude above which radiative recombination dominates radiative association will not be known, however, until the appropriate γ are accurately determined Somewhere below 100 km the three body recombination process must become more important than radiative association Values for γ and β are needed The crossover point occurs where $\gamma[O_2] = \beta[O_2]^2$, that is $[O_2] = \gamma/\beta$

The reaction $X^+ + O_2 \rightarrow OX^+ + O$ cannot remove metallic ions because the dissociation energies of FeO$^+$, MgO$^+$, seem to be less than for oxygen, 5 1 eV, making such reactions endothermic An exception may be $Si^+ + O_2 \rightarrow SiO^+ + O$ if the dissociation energy of SiO$^+$ is 5 66 eV (ref 3) All metallic ion reactions with nitrogen, $X^+ + N_2 \rightarrow XN^+ + N$, are presumably endothermic The dissociation energy of nitrogen is large, 9 76 eV

In conclusion, then, radiative association processes, hitherto believed unimportant in the ionosphere, may be an important mechanism in the neutralization of metallic ions near 100 km Three body reactions probably dominate near 90 km and below

Calcian Dolomites and Dedolomitization

THE dedolomitization process, first named in 1847 (ref 1), has recently found increasing recognition, and has been reviewed briefly by Friedman and Sanders[2]

Three different mechanisms have been suggested to explain this process First, dedolomitization is a surface feature, and thus part of chemical weathering[3-5], second, reaction of dolomite with solutions containing sulphate results in the formation of calcite and soluble magnesium sulphate[1,6-8], and third, dedolomitization is a diagenetic process, related to physico-chemical changes in the overlying and interstitial water system[9,10] The evidence presented here not only strongly favours the diagenetic theory of dedolomitization, but points to an early stage of diagenesis and to the importance of particular crystallochemical features of the original dolomite crystals

During a study of eighty-five samples of sedimentary carbonate rock from Israel, ranging in age from Jurassic to Turonian dedolomitization was found to affect only calcian dolomites, that is, those containing at least 8 per cent calcium in excess of the ideal composition of dolomite (Ca Mg = 1 1 molar) (I collected and analysed forty-five samples of rocks from the Mahmal Formation (Jurassic) in Makhtesh Ramon, and E Sass chemically analysed forty samples of Cenomanian and Turonian age)

The fact that this state of calcium excess is original and antedates dedolomitization is shown by several samples in which the ratio of calcium to magnesium is not the same throughout the calcian dolomite crystal, but is zoned, parallel to its rhombohedral outline This variation in composition which was revealed by several independent observations was confirmed by electron probe analyses of two specially chosen crystals, and is analogous to the well known zoned distribution of iron in ferroan dolomites

X-ray powder patterns show that calcian dolomite crystals, which look perfectly homogeneous under polarized light, are aggregates of subparallel crystallites, less than 100 Å in diameter This crystal mosaic[12] results from the introduction of calcium ions into the sites of magnesium ions in the dolomite lattice Because calcium ions are larger than magnesium ions, lattice defects increase with growth and limit the size of the crystallites

The preferential dedolomitization of calcian dolomites or of zones or cores in dolomite crystals which are relatively rich in calcium can be explained by (*a*) the increase in free energy of calcian dolomite compared with "normal" dolomite, or (*b*) the ease of replacing calcium ions in the microcrystalline aggregate through the intercrystallite boundaries

Dedolomitization occurs either after the formation of a calcian dolomite crystal or at definite intervals during the growth of a dolomite crystal In the latter case, the replacing calcite will constitute rhombohedral cores or zones within the dolomite crystal In the Jurassic samples as many as three calcite zones are observed in individual crystals The early age of this dedolomitic calcite is shown by its frequent intimate association with zones of haematite within crystals of ferroan dolomite These zones are followed towards the outside by non-oxidized ferroan dolomite, and therefore represent interruptions in the process of crystal growth

Further evidence for the early diagenetic character of dedolomitization is provided by the presence of numerous dedolomitic intraclasts in different dolomites, which are not affected by this process

Calcian dolomites probably form in a geochemical environment intermediate between that corresponding to the formation calcite and "normal" dolomite respectively Dedolomitization occurred if and when the chemical system shifted towards the calcite stability field during diagenesis These conclusions agree well with the observation[5] that, in a given dolomitic limestone, increasing calcite content is associated with an increasing content of calcium ions in the dolomite crystals

A surface layer, rich in calcium (Ca Mg = 4 1) and about 100 Å thick, has been found on Recent dolomite crystals[11] This could represent one of the zones rich in calcium the development of which has just been described Because of the very high calcium content of ions in this surface layer, the considerably thicker calcian dolomite zones in older dolomite crystals have to be explained by the short range diffusion of calcium ions into the adjoining "normal" zones

I found no evidence in favour of the "sulphate hypothesis" during this investigation Sulphate is absent, or present only in traces Some rocks contain geothite, pseudomorphous after pyrite, but there was no dedolomitization in these rocks

Dedolomitization in the Jurassic rocks which I have studied is therefore an early diagenetic process There was no indication of surface weathering, such as an increase in the ratio of calcium to magnesium towards the exposed rock surfaces This does not exclude the possibility of dedolomitization being induced by surface weathering in special conditions, for example, along joints or associated with the formation of caliche.

PHYSICS

Radio Pulses from Extensive Air Showers at 520 MHz

RADIO pulses at frequencies below 100 MHz have been detected in association with extensive air showers at the zenith by many workers[1–6], and subsequently at large zenith angles[7,8] Current theories do not predict a detectable flux of radio frequency power at frequencies greater than 100 MHz—the highly idealized model of Kahn and Lerche[9] imposes a limiting frequency, because of coherence conditions. of about 75 MHz, while Colgate[10] predicts a maximum emission at 1 MHz Tentative evidence supporting these predictions has been found in several experiments[1,2,5] Because of the nature of the theoretical models used and the possibility of other mechanisms contributing strongly in the ultra high frequency region of the spectrum, an investigation at a frequency greater than 100 MHz was undertaken

In this experiment, a master pulse (Fegan *et al* [11]), generated by a phased coincidence between two 44 MHz receivers (system beamwidth ± 35°), was used to interrogate the outputs of both a 520 MHz receiver and a particle detector The former consisted of a nineteen element Yagi antenna connected through a masthead tuned pre-amplifier and a line repeater to a radar scanning receiver (detector bandwidth $d\nu = 2$ MHz) All radio systems were orientated, at a zenith angle of about 80°, towards geomagnetic west, and were aligned using a hydrogen filled spark gap The particle detector, of 1 m^2 sensitive area, consisted of sixty liquid scintillation modules in a staggered vertical array, viewed by a 5 in photomultiplier tube; it was biased to operate at the single μ-meson level The system was operated only during night hours because of a high man-made interference level in the radio receivers by day

In the analysis of results obtained during [illegible] months running time, a coincidence ($\tau = 1$ μsec) between the master radio pulse and a particle in the detector was assumed to be caused by an extensive air shower and classified as an event. During 340 h of observation, seventy events were recorded It proved feasible to trace sixty-three out of seventy of the ultra high frequency video output waveforms associated with these events, each tracing being of 20 μsec duration. The other seven were not resolvable because of prohibitively high triggering rates A bandwidth-limited pulse, which occurred at the expected position of such tracings and which was greater than 1·5 times the average noise fluctuation of the trace, was taken to indicate ultra high frequency radio emission accompanying an extensive air shower Eleven such pulses were observed, varying in amplitude from 1 5 to 3 0 times, the average noise fluctuation with no other large pulse appearing at any point along the trace No pulses of comparable magnitude were found at any point on the other fifty-two tracings and at no time was the receiver saturated

To eliminate the possibility of (*a*) random coincidences between radio and particle systems giving rise to the seventy events, and (*b*) spurious pick-up within the display and trigger electronics giving rise to ultra high frequency pulses, two subsidiary experiments were carried out

(*a*) The observed μ-meson master pulse coincidence rate of about 0 2 h^{-1} was well above the calculated random rate of 0·01 h^{-1} To verify this the scintillation medium was screened off and both a cobalt-60 gamma source and a scintillation crystal were substituted in front of the photomultiplier tube The discriminator was slightly adjusted to give the same rate as previously, but all other parameters of the radio systems remained the same. No coincidence was observed in 32 h of observation, indicating that the observed events were unlikely to be random coincidences

(*b*) The 44 MHz receivers were disconnected and artificial pulses injected at random into (i) the trigger system and (ii) the display electronics If pick-up were absent no cumulative effect would be expected at any point of the corresponding ultra high frequency time base tracings Sixty ultra high frequency tracings obtained by (i) and one hundred and thirty obtained by (ii) have shown no such cumulative effect.

In a more detailed analysis of results, all traces were divided into ten channels and the amplitude of the largest pulse on each trace together with its position were noted Histograms of the integrated amplitudes were drawn—in (*A*) for the sixty-three events and in (*B*) and (*C*) for the different modes of random triggering. All three histograms were normalized at the same mean amplitude for channels 3 to 10 The expected position for genuine events lies between channels 1 and 2. The histograms are shown in Fig 1 Histogram (*A*) shows a significant positive effect in the expected position, the integrated amplitudes being 12 and 10 standard deviations above the mean in channels 1 and 2, respectively; whereas in (*B*) and (*C*) the slight positive effect is not statistically significant, being at most only 2 standard deviations above the mean

The sixty-three events which comprise histogram (*A*) denote an integral representation of the detected pulse amplitude. The amplitudes of these ultra high frequency events were converted to corresponding energies at the input by allowing for the detector law; and an integrated spectrum of the form $N(>E) = k(E)^{-\gamma}$ was drawn. An equivalent noise spectrum, based on the amplitude analysis of channels 9 and 10 of the same traces, was also drawn. The exponent for the pulse spectrum was 2 0±0 6, while that for the noise spectrum was 4 7±1 6. With the detector used and for the pulse amplitudes considered, $V_{\mathrm{out}} \propto E_{\mathrm{in}} \propto (V_{\mathrm{in}})^2$ For a coherent signal the expected value of γ is about 1 1, and for an incoherent mechanism 2 2, assuming that the shower energies are in the region, 10^{16}–10^{19} eV The observed value may therefore indicate that ultra high frequency emission is caused by incoherent radiation from extensive air showers.

In conclusion, it seems that, using a radio-particle coincidence, tentative evidence has been obtained for ultra high frequency radio emission from extensive air showers. This emission is consistent with an incoherent process Radio bremsstrahlung from delta ray electrons

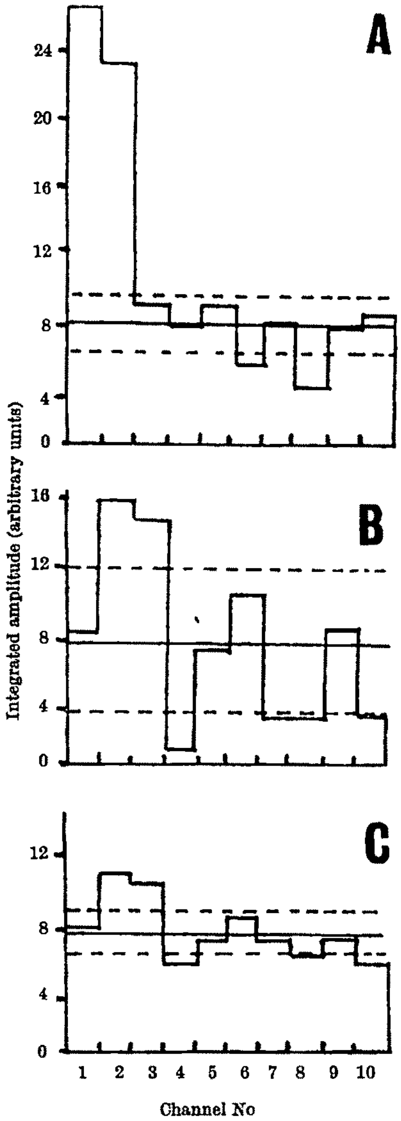

Fig 1 Histograms of the integrated amplitudes, *A* for the sixty-three events and *B* and *C* for the different modes of random triggering All three histograms are normalized at the same mean amplitude for channels 3 to 10 ———, Mean, - - -, standard deviation

has been postulated by Rosenthal and Filchenkov[12], and later re-examined by Charman and Jelley[13], who conclude that the intensity of radiation in the radio spectrum from this mechanism is insignificant compared with the geomagnetic effects Isotropic recombination radiation from atmospheric atoms and molecules, or the radiative Coulomb scattering of low energy shower electrons, are further possible mechanisms for ultra high frequency emission. The detailed quantum mechanical problems involved in calculating the power output for the latter process are considerable[14]

THE SOLID STATE

Porous Layers at Glass Surfaces

PREVIOUS investigations have shown that porous modifications of the surfaces of glasses may be formed by the action of liquid water[1] and water vapour[2]. I have now studied the formation of porosity in the surface of grains of soda–lime–silica glass in various conditions.

Table 1 COMPOSITION OF SODA–LIME–SILICA GLASS

Component	Percent by weight
Silica	72 6
Calcium oxide	8 2
Sodium oxide	13 5
Potassium oxide	0 4
Magnesium oxide	3 9
Alumina	1 0
Sulphur trioxide	0·2
Total iron (expressed as ferric oxide)	0 15

The glass has the composition shown in Table 1 Structural properties of the grains were inferred from benzene physical adsorption isotherms measured by frontal and elution gas chromatography[1]. The monolayer capacity (N_m) was determined from the Brunauer–Emmett–Teller (BET) equation

$$\frac{P}{N(P_0-P)} = \frac{1}{N_m c} + \frac{(c-1)}{N_m c}\cdot\frac{P}{P_0} \qquad (1)$$

where P is the pressure of adsorbate in the gas phase in equilibrium with N moles of adsorbed adsorbate; N_m is the amount of adsorbate in the first adsorbed layer and may be readily related to the surface area of the adsorbent if the adsorbed molecules conform to a close packed configuration; P_0 is the saturation vapour pressure of the adsorbate, and the constant c is related to the average heat of formation of the monolayer, E_1, by the equation

$$c = \varphi \exp \frac{E_1 - E_L}{R\ T}$$

where φ is the ratio of the evaporation–condensation coefficients for the first and higher adsorbed layers and may often be approximated to unity[1], R is the gas constant, T is the absolute temperature at which the isotherm was measured, and E_L is the heat of condensation of the adsorbate The BET parameters for various treated grains are given in Table 2

Degassing treatments involved heating the grains for 3 h in a stream of dry nitrogen Isotherms measured after 3 h degassing and after a further 6 h degassing at the same temperature were in excellent agreement For the water treatment, 24 g of grains of approximately 160μ diameter (but containing an appreciable quantity of fine material) was heated in 100 ml of distilled water under reflux for 24 h After this time, the pH of the water was in the region 10 to 11 The alkali treatment involved heating the grains at 100° C in 10 per cent sodium

Table 2. SUMMARY OF BET PARAMETERS FOR BENZENE ADSORPTION ISOTHERMS AT 40° C

Treatment	Degassing temperature (°C)	$N_m \times 10^7$ mole g^{-1}	c
None	100	4.86	10.43
Water	50	18.30	8.16
	100	18.50	7.36
	150	17.70	8.63
	200	15.08	7.54
	245	13.71	9.23
	300	14.07	6.71
	350	13.94	7.84
	400	14.73	7.38
	450	13.90	5.80
	500	13.70	5.38
Rehydration	50	15.79	7.00
Sodium hydroxide	100	1,766.00	23.60
	400	1,577.00	14.41
Rehydration	100	2,348.00	11.83

hydroxide w/v. In both instances, the treated grains were finally washed in a stream of distilled water. Rehydration was effected by passing a stream of water over the grains for 24 h at 90° C.

The water treatment increased N_m and hence the surface area (because there is a surplus of hydroxyl adsorption sites for the adsorbate to conform to a close packed structure in the monolayer) by a factor of four. From the value of c, which is related to the heat of adsorption[1], it may be concluded that pores in the modified surface are greater than 35 Å in diameter[3]. The decrease in c value induced by the water treatment may be attributed to the different chemical compositions of the two surfaces, as a result of the preferential leaching of the weathering process. Alternatively, the ratio of free hydroxyl groups (which are the strongest sites for adsorption[4]) to adjacent hydroxyl groups which are cross hydrogen bonded may differ for surfaces produced by the two hydroxylation processes, namely the water treatment of the grains and the production of the grains by crushing glass in a humid atmosphere. Separate experiments have shown that the c value was 10 for freshly prepared vitreous silica grains. This would favour the latter mechanism, that is, the existence of more single hydroxyl groups on the freshly prepared grains than on the weathered grains.

Thermally degassing the grains at successively higher temperatures causes a general decrease in N_m and c. It is possible that at the higher degassing temperatures, steric effects control adsorption, because benzene is adsorbed specifically on surface hydroxyl groups. Thus the removal of these hydroxyl groups by heating the adsorbent would not only decrease the heat of adsorption, and hence c, but the adsorbed benzene molecules may not conform to a close packed configuration, for close packing, a surface hydroxyl concentration of greater than 2.4 hydroxyl groups/100 Å^2 is required, and at 500° C this concentration is within the range 1.6 to 2.9 (ref. 4). The increase in values of N_m and c after rehydration of the surface substantiates the existence of these steric effects. The reasons for N_m not returning to its original value may be explained in two ways. First, the degassing procedure causes an irreversible sintering process and consequent loss of surface area to occur within the porous layer. Second, the porous layer undergoes an irreversible shrinking process which would also cause a decrease in surface area. Because the degassing temperatures involved are rather low for sintering processes, it seems probable that the second mechanism has occurred, and this most likely over the temperature range up to 200° C.

Adsorption of benzene on glass surfaces which have been attacked by strong alkali shows high values for N_m and c. The high c value is indicative of the presence of micropores (that is, pores of less than 35 Å diameter) because the potential fields of the opposite walls of micropores overlap and are responsible for the high attractive force (and high heat of adsorption) for the adsorbate. Furthermore, it can be appreciated that because of the proximity of the pore walls, monolayer capacity has not the usual significance in microporous systems and therefore N_m cannot be readily related to the surface area, although the high value of N_m shows the extensive nature of the porous layer. The latter is confirmed by the results of the final rehydration where the low value of c indicates the absence of micropores, but the value of N_m is very large and the surface area is approximately 500 times its initial value. Thermal ageing of the microporous system shows, once again, a decrease in N_m and c. It was observed that if the microporous grains were immersed in water, the pH of the water rose at an appreciable rate. Rehydration therefore removes material which was responsible for the microporosity.

The following principal conclusions may be stated. When the soda–lime–silica glass is only lightly attacked by water or dilute alkali, a wide pore structure is formed which has thermal ageing properties similar to silica gel[5]. It is unlikely that the porous structure is globular, however, because the silica content of the glass is large enough for the wide pore structure, formed by a preferential leaching process, to be a continuous silica network. The microporous structure contained in the extensive wide pore structure (also observed by Liberti[6]) is probably formed from soluble or partly soluble reaction products which have not been removed from the deep porous layer.

Preparation of Fibre Reinforced Nickel–Gold Alloys using a Solid State Reaction

THE most obvious and frequently used method of making fibre reinforced alloys is to take fibres of a metal or alloy with a relatively high melting point and permit a matrix of metal or alloy with a lower melting point to solidify around them. A more sophisticated approach, which has received attention for a number of years, is to attempt to grow the fibres *in situ* within the matrix. This has been achieved by Hertzberg[1,2] and others using a technique in which eutectic alloys are permitted to undergo unidirectional solidification. This method is, however, rather limited in application because the alloy composition, and thus the volume fraction of fibres, is fixed. This communication gives a preliminary account of another technique that we have recently developed which does not suffer from this limitation.

This new method, which uses a solid state reaction to create the fibres, has been demonstrated using alloys in the gold–nickel system. The phase diagram for this system, which contains a simple miscibility gap, is shown in Fig. 1. In a series of experiments on the equiatomic alloy, the specimens were solution treated at 900° C, quenched at room temperature and then aged, usually for 1 h, at various temperatures within the miscibility gap. It was found that at temperatures above about 400° C the metastable solid solution which formed on quenching dissociated directly into the two equilibrium phases by a discontinuous solid state reaction which nucleated at grain boundaries. The reaction rate was found to go through a maximum at about 600° C, and it became infinitesimally small as the miscibility gap boundary was approached.

When the reaction products were examined by stereoscopic electron microscopy using a replica technique, it was found that at the lowest reaction temperatures the nickel rich phase was precipitated in the form of roughly spherical particles with diameters up to about 1000 Å within a matrix of the gold rich phase. As the reaction temperature increased the particles formed became larger, and then near 700° C the morphology changes to fibres a few tenths of a micron in diameter and many microns in length. In each grain several discrete fibre orientations were observed. Mechanical property studies showed that the small spherical particles produced a strong strengthening effect, but there seemed to be no significant effects attributable to the fibres. The volume fraction of fibres was, however, only a few per cent and so this was not considered surprising.

The occurrence of only a few per cent of the nickel rich phase, that is of fibres, in the equiatomic alloy after equilibration at 700° C is consistent with the phase diagram and results from the marked asymmetry in the miscibility gap. This may readily be seen by applying the lever rule to this case. The lever rule also predicts, of course, that the proportion of the nickel rich phase should increase with increasing nickel content. This suggested to us that higher volume fraction of fibres might be obtainable by using alloys containing more than 50 atomic per cent nickel. Accordingly, the experiments were repeated using alloys containing 50, 55, 60, 65 and 70 atomic per cent nickel. This time, however, hardness rather than mechanical property measurements was used to assess strengthening effects.

The results of this work showed that the morphology and kinetics of the dissociation reaction changed little with composition except that, as expected, the volume fraction of the nickel rich phase increased with increasing nickel content. In particular, the volume fraction of fibres increased and in the alloy having the highest nickel content exceeded 50 per cent. The fibres could be seen most convincingly in the stereoscopic pairs of electron micrographs, but quite convincing conventional electron micrographs were also obtained by careful manipulation of the shadowing technique. One of these, in this case for an alloy containing 60 atomic per cent nickel, is shown in Fig. 2. The hardness measurements showed peaks caused by fibres in every case except that of the equiatomic alloy, thus demonstrating that the fibres do cause reinforcement when there are enough of them. The results for the alloy containing 70 atomic per cent nickel are shown in Fig. 3. The peak at 450° C is caused by the small spherical particles and that at 700° C by the fibres.

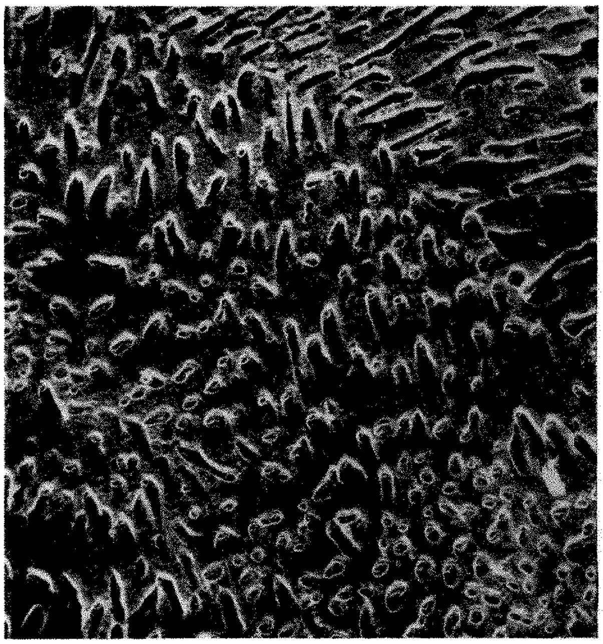

Fig. 2. Nickel rich fibres in an alloy containing 60 atomic per cent nickel and 40 atomic per cent gold (× 6,000).

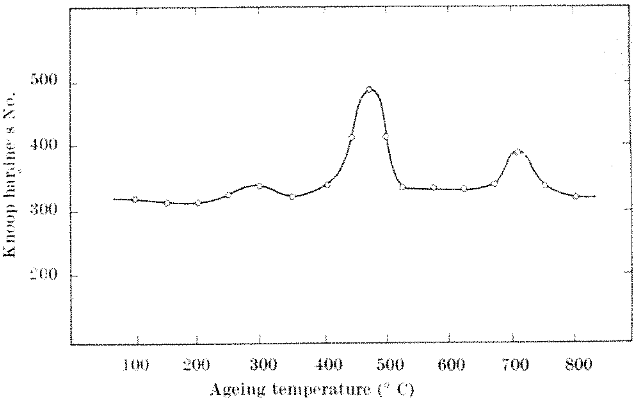

Fig. 3. An isochronal hardening curve for an alloy containing 70 atomic per cent nickel and 30 atomic per cent gold.

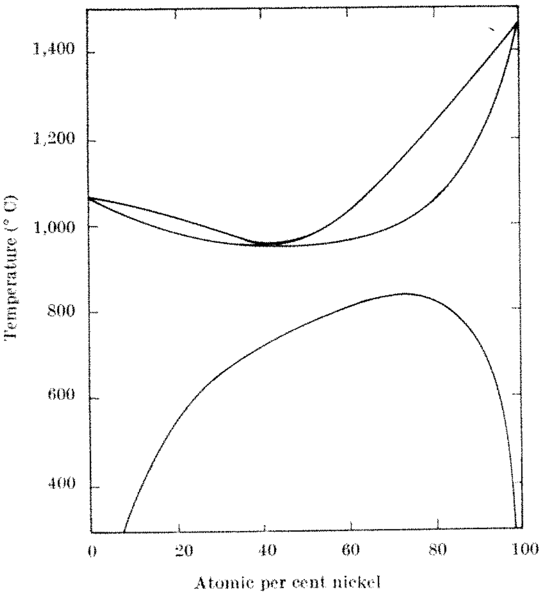

Fig. 1. The gold–nickel phase diagram.

Although these experiments show unequivocably that fibre composite nickel–gold alloys can be prepared, and that the fibres produce a strengthening effect, proper control of the fibre orientations to give directional strengthening has yet to be achieved. Experiments using directional heat treatments, and heat treatments in a magnetic field, are now in progress in our laboratory and may accomplish this. The applicability of the method to other alloy systems also remains to be explored. There are many other systems with miscibility gaps, but presumably the existence of a miscibility gap is not the only criterion to be satisfied before the method will work. It seems likely, for example, that the interfacial energy of the two equilibrium phases has to be highly anisotropic if fibres rather than spheres are to be formed.

This work was carried out while one of us (J. O.) was the recipient of a NASA traineeship. Financial support for the project was provided by the US National Institute of Dental Research.

Synthesis of Optical Quality Proustite and Pyrargyrite

The compounds silver orthothioarsenite, Ag_3AsS_3, and silver orthothioantimonite, Ag_3SbS_3, occur in nature as small imperfect crystals and have been given the mineral names proustite and pyrargyrite, respectively. Harker[1] determined their structures and assigned them to the space group $R3c$. They are non-centrosymmetric uniaxial crystals with a large refractive index, large negative birefringence ($n_0 - n_e > 0{\cdot}2$) and transmission over a wide spectral range (0·6–13 μm). They also exhibit semiconducting, photoconducting and piezoelectric properties.

It was thought that these materials, having such properties, might have useful applications in non-linear optics (K. F. Hulme and J. Warner, personal communication). Previous attempts to synthesize these compounds have been made by crystallization from aqueous solution[2], by melt growth[2-4] and by hydrothermal growth[5,6]. The latter resulted in transparent crystals of maximum dimension < 1 mm; other methods yielded opaque polycrystalline material. We have succeeded in growing large single crystals suitable for the proposed applications[7].

The compounds may be considered as binary mixtures of two sulphides and the appropriate phase diagrams are known[8,9]. Because the two compounds are so similar we shall describe only the growth of Ag_3AsS_3 (melting point 480° ± 3° C (M. M. Faktor, private communication). The growth of Ag_3SbS_3 follows a very similar pattern. In the preliminary experiments, we melted together stoichiometric proportions of high purity silver sulphide and arsenic trisulphide (British Drug Houses, Ltd., Poole, Dorset) in sealed quartz tubes and solidified the melts by the normal freeze method at rates from 5 to 200 mm/h. These experiments yielded opaque products. No improvement was obtained by varying the composition of the melt about the stoichiometric composition. We confirmed the low vapour pressure of volatile components over the melt, previously reported by Wernick[3,4]. Zone refining at various rates in the range 5 to 25 mm/h for up to thirty passes, taking care to avoid loss of volatile constituents, yielded translucent material of large grain size which contained numerous inclusions throughout, as shown in Fig. 1.

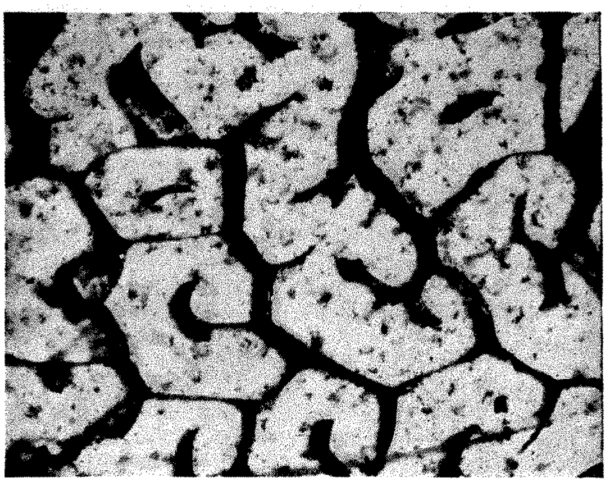

Fig. 1. Transmission micrograph of a slice of ingot showing characteristic cellular growth (× c. 57).

Careful microscopic examination of the ingots showed a cellular structure characteristic of constitutional supercooling[10]. We therefore decreased the growth rate and increased the imposed temperature gradient until at a growth rate of 8 mm/day and with a temperature gradient of 6 C°/mm at the liquid–solid interface we obtained large single crystals which were devoid of cellular structure and inclusions which result from the entrapment of melt[11] in the cell walls. Crystals of 12 mm diameter and 50 mm length have been grown in sealed quartz tubes by normal freezing of molten Ag_3AsS_3 in both vertical and horizontal apparatus. The melt can exhibit considerable supercooling; as much as 20 mm length has been observed to grow rapidly after nucleation. We found it convenient to rapidly freeze the first part of the melt and then to melt back to leave a 2–3 mm seed of polycrystalline material from which to propagate slow growth. Single crystals are readily obtained by promoting growth through a constriction in the quartz tube; in the case of vertical growth it was found that ten of the first twelve crystals grown were oriented within 30° of the optic axis.

The interesting optical parameters and the potential uses of this material have been described elsewhere[7]. Examination of the conoscopic figure in polished slices indicates that there is little strain in the crystals as grown. Although we have not yet found a suitable etch to reveal the dislocation content, the uniformity of extinction between crossed Nicols indicates a reasonable quality of single crystals.

The total impurity content of the material used was approximately 450 p.p.m. (excluding 250 p.p.m. of antimony). Of this 450 p.p.m., 200 p.p.m. was selenium, 100 p.p.m. was iron and other appreciable impurities were silicon, gold, lead and copper. The cellular structure obtained under the conditions quoted is unlikely to be caused by impurity segregation and indeed the zone-refined material showed no improvement. Segregation of the chief components of the melt is more likely the cause of the cell structure observed[12]. Treating the compound as a pseudo-binary compound of Ag_2S and As_2S_3, it was determined experimentally that with a growth speed of 8 mm/day and an imposed temperature gradient of 6 C°/mm the onset of cellular structure occurs when the concentration of arsenic trisulphide in the melt falls outside the approximate limits 22–28 mol per cent; at a growth speed of 4 mm/day and with the same temperature gradient these limits widen to approximately 18–32 mol per cent of arsenic trisulphide. Optical quality single crystals have been regrown in the same apparatus, however, at growth rates up to 112 mm/day without marked deterioration in crystal quality.

These results and observations show that the chief problem in growing optical quality single crystals is the occurrence of a cellular structure. As is well known[13,14], to avoid cellular growth the ratio of the growth rate to the temperature gradient in the melt must not exceed some critical value which is dependent on the degree of segregation at the solid–liquid interface. The origin of the segregation in these materials seems to be one of departure from stoichiometry rather than the presence of impurities.

MOLECULAR STRUCTURE

Experimental Observation of an Antisymmetric Raman Scattering Tensor

IT is well known that the scattering tensor for vibrational Raman scattering is symmetric[1] This is, however, not true for electronic Raman transitions (refs 1, 2 and unpublished results), and this has important implications in the selection rules for these transitions

We have recently demonstrated (ref 3, and results to be published) by *a priori* theoretical calculations the remarkable degree of antisymmetry of the scattering tensor for electronic Raman transitions of compounds containing trivalent lanthanides We report here some experimental observations of electronic Raman transitions where the antisymmetry of the scattering tensor is directly demonstrated.

In Fig 1, part of the 100° K Raman spectrum of yttrium aluminium garnet doped with about 5 per cent Eu^{3+} is shown The two relatively weak lines at 286 cm^{-1} and 307 cm^{-1} are not present in the Raman spectra of other yttrium aluminium garnet crystals and must be attributed to electronic Raman transitions taking place between the $^7F_0$ groundstate and the crystal field $^7F_1$ levels of the Eu^{3+} ion (The possibility of the observed lines being caused by local mode vibrations can be excluded because of the temperature dependence and the intensity of the transitions) The positions of the electronic levels as found from the Raman spectrum are in perfect agreement with the corresponding values derived from the optical fluorescence and absorption spectra[4]

Raman spectra of crystals of yttrium gallium garnet and yttrium vanadate doped with small amounts of trivalent europium have been reported previously[5,6]. Also in these other lattices electronic Raman transitions between levels of $^7F_0$ and $^7F_1$ have been found, so that the occurrence of electronic Raman transitions between these two levels must now be considered to be firmly established

According to Placzek[1] the components of the scattering tensor must transform as the matrix element $<\psi_r|\alpha_{\varrho\sigma}|\psi_k>$, where ψ_r and ψ are the wave functions for the levels between which the Raman transitions take place For the low lying electronic states of rare earth ions in crystals, the total angular momentum, $\mathcal{J}$, can be considered to be a good quantum number so that, neglecting the crystal field splitting of the excited state, the transformation properties of the scattering tensor will be determined by the symmetry operations in the total rotation group It is well known that it is possible to reduce the conventional cartesian tensor to a sum of three irreducible tensors which transform as states of total angular momentum 0, 1 and 2, respectively. The unitary transformation linking the cartesian basis set to the irreducible set has been given elsewhere[7] and it is found that the antisymmetric part of the scattering tensor is determined solely by that part of the irreducible tensor with angular momentum $\mathcal{J}=1$

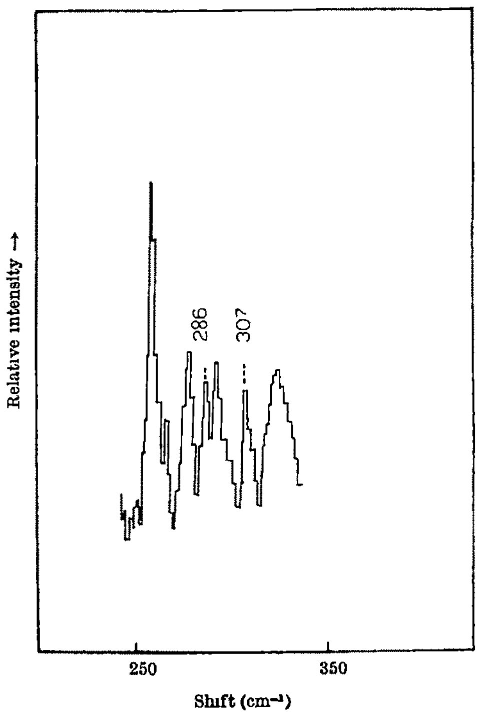

Fig 1 Part of the Raman spectrum of Eu^{3+} in yttrium aluminium garnet The spectrum was excited with the 6328 Å radiation of a helium–neon laser The time lapse between successive steps was 16 sec

For the trivalent europium ion the total angular momentum of the groundstate is equal to zero while the angular momentum of the first excited state is equal to one From the vector model of the addition of two angular momenta it is then found that only that part of the scattering tensor with quantum number $\mathcal{J}=1$ is non-vanishing for the electronic Raman transition $^7F_0 \rightarrow {}^7F_1$ That such a transition is readily observed is then an experimental proof of the theoretical prediction given previously that the scattering tensor for electronic Raman transitions of rare earth ions in crystals is highly asymmetric

This has important implications for the selection rules of electronic Raman transitions as compared with the conventional Raman effect For the latter the selection rules will be given completely by the transformation properties of products of the type $xy+yx$ and tabulations of these products can be found in many places (see, for example, ref. 8) For the electronic Raman effect, however, terms of the type $xy-yx$ also contribute and it should be remembered that the operators in the product do not commute so that this difference is usually a non-vanishing quantity. The transformation properties of this antisymmetric part can, of course, be handled by the powerful means of tensor operators, but there is an easier way out.

The antisymmetric part transforms under all rotations as a vector, but under inversion as an axial rather than a polar vector[9] The same is true for the transformation properties of rotation about cartesian axis, so that the transformation properties of the antisymmetric part of the scattering tensor can be found directly from the character tables given, for example in Wilson Decius and Cross[8]

Mossbauer Effect Study of the State of Iron in Spinach Ferredoxin

THE ferredoxins are an important group of enzymes which catalyse photochemical reactions in plants and photosynthetic bacteria They contain non-haem iron which is believed to be close to the active centre but which is in a chemical form which has not been unambiguously determined Spinach ferredoxin is one of the simpler of these compounds, has a molecular weight of about 12,000 and contains two iron atoms/molecule A Mossbauer study on this system has been made by Bearden and Moss[1] and on other non-haem iron proteins by several groups[2-4] In this communication, we describe Mossbauer effect measurements made both in the presence and absence of a magnetic field on spinach ferredoxin, and it is concluded that the iron atoms are both low-spin Fe^{2+} in the oxidized state, and there is one low-spin Fe^{2+} and one high-spin Fe^{2+} in the reduced state

The Mossbauer effect has become an extremely powerful technique for the study of the oxidation state of atoms because (1) it is non-destructive, in contrast to chemical methods, (2) it is a property of a specific nucleus (for example, iron-57), enabling investigations without knowing the complete X-ray structure of the molecule, and (3) the atoms can be identified, unlike in electron spin resonance or susceptibility measurements

The non-haem iron proteins give no electron spin resonance signal in the oxidized state, but on reduction they show an anisotropic resonance centred about $g = 1$ 94, which is quite unlike those found in any other compound of iron investigated For spinach ferredoxin, the values are $g_x = 1$ 89, $g_y = 1$ 94 and $g_z = 2$ 04 (ref 5) The structure and state of the iron atoms are not known, though it has been assumed from the similarity of the electron spin resonance signals that it is the same for all the compounds The electron spin resonance line was broadened when one of these proteins (*Azotobacter vinlandii*) was enriched with iron-57 (ref 6) and sulphur-33 (ref 7), which suggested that the resonance arises from iron atoms which have sulphur neighbours Bayer *et al* [8] have made ferredoxin which is free from iron (apoferredoxin) which shows no electron spin resonance signal, but on re-incorporation of the iron the $g = 1$ 94 signal reappears

Thus electron spin resonance measurements do not enable us to establish the valence state of the iron atoms and hence the Mossbauer effect may, in principle, be especially valuable here Because in highly covalent compounds the isomer shift is not very sensitive to the state of iron, we studied the magnetic hyperfine interactions which together with isomer shift measurements may distinguish between high and low spin states, as well as between ferrous and ferric assignments The spectra observed in strong magnetic fields at low temperatures are complicated for polycrystalline materials by the effects of magnetic anisotropy and quadrupole splittings, but nevertheless certain usual features may be enumerated[9] (1) High spin Fe^{3+} shows a sharp six line pattern corresponding to an effective magnetic field at the nucleus of 400 to 600 k gauss[10,11] because the ion is isotropic or almost isotropic (2) Low spin Fe^{3+} shows much broader lines because it has a large electric field gradient and anisotropic g-values ranging between 1 and 3, although usually a six line pattern may be distinguished which corresponds to an effective field of 200 to 300 k gauss (3) High spin Fe^{2+} may show a wide variety of possible Mossbauer spectra in magnetic fields because the quadrupole coupling and the g-values are sensitive to its ligand environment (4) Low spin Fe^{2+} shows[10] only a small broadening caused by the direct effect of the external magnetic field on the nucleus because this ion is non-magnetic and thus the internal field is zero

Thus observations of the effect of a magnetic field on a non-magnetic Mossbauer spectrum should clearly identify high spin Fe^{3+} or low spin Fe^{2+} The remaining configurations of single ions low spin Fe^{3+} and high spin Fe^{2+}, should be distinguishable by the large positive isomer shift (1 mm/sec or more) of the latter

Spinach ferredoxin was prepared from spinach bought in the market which was carefully selected, washed and then stored at − 20° C The purification procedure was a modification of the method of Hill and Bendall[12] We used Whatman *DE*22 anion exchangers, slightly different concentrations of acetate buffer, pH 5 5, and did not attempt to crystallize the protein The specimens were in frozen aqueous solution and the iron was not exchanged for enriched iron-57 so as to avoid any possible damage to the molecule, thus the intensity of the Mossbauer effect was weak but not impossibly weak The samples, 0 7 ml in volume, were estimated to contain 118 mg ferredoxin/ml , based on $E_{420} = 10$ 32 cm^{-1} $mmoles^{-1}$

The Mossbauer spectra were measured using the spinach ferredoxin as the absorber and cobalt-57 in chromium as a source of mono-energetic 14 4 keV gamma rays The source was driven on the vibrator designed by Cranshaw[13], and the spectra were recorded on a multichannel analyser

The spectra were measured for both oxidized and reduced ferredoxin Reduction was produced with sodium dithionite, and was monitored by observing the electron spin resonance signal both before and after the Mossbauer effect measurement The specimens were also checked for biological activity immediately after being prepared The Mossbauer spectra were measured at temperatures of 195° K, 77° K, 4 2° K and 1 5° K At the latter two temperatures magnetic fields of up to 30 k gauss could be applied Fields up to 5 k gauss were produced by an iron cored electromagnet Fields up to 30 k gauss were produced by a superconducting solenoid

After measurement the reduced samples were further checked for possible deterioration by allowing them to melt and re-oxidize in air, when they gave no electron spin resonance signal, but gave the Mossbauer spectrum of Fig 1 (*a*) and were still active On re-addition of dithionite the reduced spectra of Fig 1 (*b*) reappeared

The Mossbauer spectrum of oxidized spinach ferredoxin at 77° K is shown in Fig 1 (*a*) The spectrum at 4 2° K is similar, and agrees in general with those of Bearden and Moss[1], as does that of the reduced sample It consists of a pair of quadrupole split lines of almost equal intensity with separation of 0 6 mm/sec, and with an isomer shift of 0 2 mm/sec with respect to iron metal The spectrum

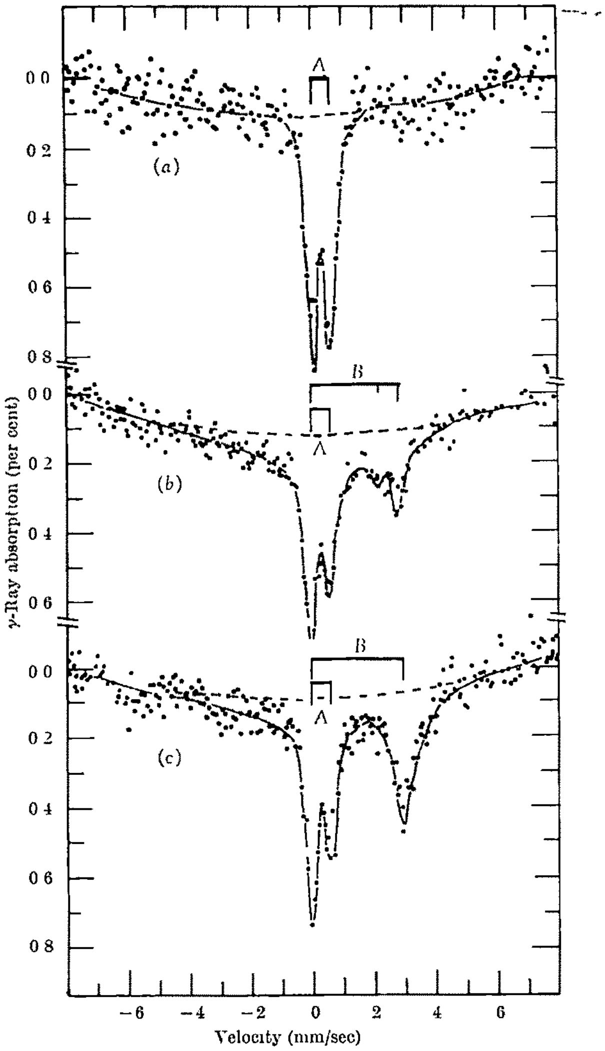

Fig. 1. Mossbauer spectra of spinach ferredoxin. (a) Oxidized, $T=77°$ K, (b) reduced, $T=77°$ K, (c) reduced, $T=4.2°$ K. The dashed line corresponds to the zero of absorption and is curved because of geometrical effects. Decomposition into the spectra A and B is described in the text.

varied only slightly between 195° K and 1.5° K. Further absorption was looked for at velocities up to ± 8 mm/sec but was not found. Application of an external magnetic field of 30 k gauss at temperatures between 1.5° and 4.2° K produced only a small broadening of the lines, corresponding to the iron being in a non-magnetic state. This suggests that the two iron atoms are both in a low spin Fe^{2+} state.

The spectrum at 77° K and at 4.2° K of reduced spinach ferredoxin is shown in Figs. 1 (b) and (c), respectively. It seems to consist of a pair of lines of unequal intensity at the same velocities (−0.1 and +0.5 mm/sec) as in the oxidized spectrum, and in addition a line or lines at positive velocities of between 2 and 3 mm/sec, which are temperature dependent. At 4.2° K there is a line at +2.9 mm/sec which appears to become less intense as the temperature increases. This seems to be caused by some of the absorption moving to lower velocities (about +2 mm/sec) and there is also a slight change in the line at +0.6 mm/sec which is sharper at 77° K than at 4.2° K.

The simplest interpretation of the spectrum at 4.2° K is that it consists of a superposition of a spectrum A, with a small quadrupole splitting (0.6 mm/sec) and isomer shift (+0.25 mm/sec), and a spectrum B, with a larger quadrupole splitting (about 3.0 mm/sec) and shift (about +1.5 mm/sec), in approximately equal intensities, although the spectrum with the larger splitting and shift seemed to be slightly more intense. The superposition is such that the low energy lines of each spectrum coincide so that the resulting line at −0.1 mm/sec of the composite spectrum is the deepest. It is natural to associate spectrum A with iron which has not been reduced because the lines are at velocities undistinguishable from those in the oxidized spectrum. The isomer shift and quadrupole splitting by themselves do not allow an assignment to be made for the state of these atoms. High spin Fe^{2+} can be ruled out, however, because it would have a large isomer shift and quadrupole splitting, which leaves either low spin Fe^{2+} or high or low spin Fe^{3+}. Spectrum B, if we are correct in analysing the spectrum in this way, clearly arises from high spin Fe^{2+} ions because of its large isomer shift and quadrupole splitting.

The spectra of the reduced specimen in external magnetic fields applied at 4.2° K are shown in Fig. 2. A comparison with the spectrum in zero field (Fig. 1 (c)) shows that, unlike the oxidized spectrum, an external magnetic field affects the spectrum, which shows that there are magnetic iron ions present, and is consistent with the observation of electron spin resonance in the reduced state. Spectrum A shows no internal magnetic field at the nucleus. Thus of the three possible alternatives (high spin Fe^{2+} having been already eliminated) it is identified as arising from low spin Fe^{2+} ions, as Fe^{3+} (high or low spin) would show large hyperfine fields. Spectrum B splits in the magnetic field more or less as one would expect for high spin Fe^{2+}. The spectra do not seem to vary greatly with temperature (compare spectra in 5 k gauss in Fig. 2 (a) and (b)), and a value of about 150 k gauss is deduced for the mean hyperfine field at these sites. The spectra in 30 k gauss were not as good as those in small or zero fields because the experimental geometry in the superconducting magnet was not so favourable. The principal point, however, that spectrum A is not drastically affected by an external field of 30 k gauss at 4.2° K is clear.

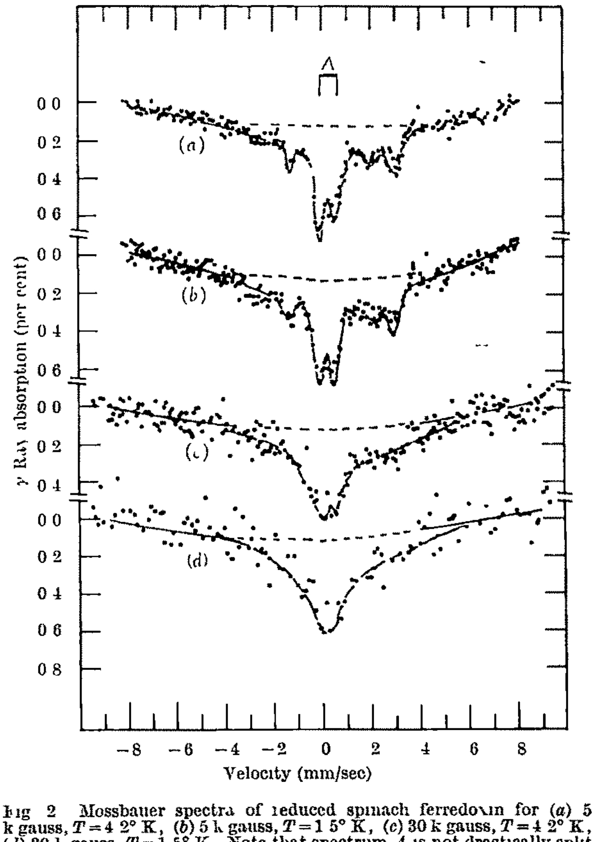

Fig. 2. Mossbauer spectra of reduced spinach ferredoxin for (a) 5 k gauss, $T=4.2°$ K, (b) 5 k gauss, $T=1.5°$ K, (c) 30 k gauss, $T=4.2°$ K, (d) 30 k gauss, $T=1.5°$ K. Note that spectrum A is not drastically split by magnetic fields.

It seems from the observed Mossbauer spectra that spinach ferredoxin in the oxidized state contains low spin Fe^{2+} ions, and that on reduction about one-half of the ions are converted into high spin Fe^{2+} ions That only a fraction of the iron atoms is affected on reduction was found previously from the intensity of the electron spin resonance signal, and it is consistent with the observation that spinach ferredoxin is a one electron donor[14]

If these assignments of the chemical states are accepted, there remain two important questions to be answered (1) how do the $g = 1\ 94$ electron spin resonance signals originate, and (2) why do only about half of the iron atoms change their state on treatment with sodium dithionite ?

Low spin Fe^{2+} has a non-magnetic ground state and so cannot give an electron spin resonance signal, while high spin Fe^{2-} usually does not give an electron spin resonance signal presumably because it is a non-Kramers ion and all degeneracies are removed by the Jahn–Teller effect Several people have proposed theories and models to explain the g-values in spinach ferredoxin (*a*) Brintzinger, Palmer and Sands[15] proposed a scheme showing that the resonance could arise from low spin Fe^{3+} tetrahedrally co-ordinated to four sulphur atoms (*b*) Gibson, Hall, Thornley and Whatley[5] proposed that in the oxidized state two high spin Fe^{3+} ions were antiferromagnetically exchange-coupled to give an $S = 0$ state, and in the reduced state one of these is converted to high spin Fe^{2+} so that the resulting Fe^{2+}–Fe^{3+} coupled system has $S = \frac{1}{2}$ and could have the observed g-values This theory has the added attraction of explaining why only half of the iron atoms may be reduced. (*c*) Blumberg and Peisach[16] proposed that the electron spin resonance arises from a free radical which is antiferromagnetically coupled to the excited ($S = 1$) state of low spin Fe^{2+}

The Mossbauer effect data on the reduced state do not seem to be consistent with model (*a*) involving low spin Fe^{3+} or (*b*) with coupled Fe^{3+}–Fe^{2+} states because the Fe^{3+} ions would give rise to a large hyperfine field when a magnetic field was applied The high isomer shift (1·5 mm/sec) of the high spin Fe^{2+} ion rules out tetrahedral co-ordination (as in (*a*)). There remains suggestion (*c*) that the iron is in a low spin Fe^{2+} state, which could fit in with the Mossbauer data of site A if the effect of the reducing agent is to produce a free radical with an unpaired electron spin, close to the iron

We would emphasize that these conclusions have been made on the assumption of simple models There is the possibility that the effective component of the hyperfine interaction tensor for site A is very small because of accidental cancellation. Such a situation occurs in ferrous chloride[17] and in the $FeCl_4^{2-}$ ion[18] Because of the small quadrupole splitting and the fact that the g-values are close to 2, however, both the dipolar and orbital hyperfine fields are small and it is unlikely that they could cancel the large negative core polarization field

It is possible that there are more than two iron sites The apparent decrease in intensity of the line at +2 9 mm/sec in the reduced spectrum at 77° K and the appearance of absorption near 2 mm/sec may result from a third iron state There also seems to be a continuous unresolved background in the spectra of the reduced samples which is not present in the oxidized form, which may be evidence for iron in a third state with relatively slow electronic relaxation rates, but which might be able to give the electron spin resonance signal

Although it therefore seems likely that spinach ferredoxin in the oxidized state contains two low spin Fe^{2+} in the molecule, and in the reduced state one low spin Fe^{2+} and one high spin Fe^{2+}, it is not possible to decide what is the origin of the $g = 1\ 94$ electron spin resonance signal until all the details of the Mossbauer spectra have been explained Studies with ferredoxin extracted from plants grown with enriched iron-57 are planned and should be valuable in understanding the details of the magnetic behaviour

We thank Professor F R Whatley and Dr T. E Cranshaw for their advice and encouragement throughout this investigation and Mrs S Druery, Miss A Telfer and Mr L W Becker for their valuable assistance. The work was partially supported by an SRC grant (to D O H).

CHEMISTRY

Visible Absorption Spectrum of Bromine Chloride

A VISIBLE and near infrared band system in emission, produced from the combination of atomic chlorine with atomic bromine, $Br + Cl + M = BrCl^* + M$, $BrCl^* = BrCl + h\nu$, has been reported recently[1] The transition involved was thought to be $^3\Pi_{0^+} \leftrightarrow {}^1\Sigma^+$ (ref. 1). Because no visible band absorption spectrum of bromine chloride has so far been published, no accurate vibrational or rotational constants for the states of this molecule are known The infrared absorption spectrum of bromine chloride[2,3] gave only an approximate value for ω_e'' of 442 5 cm^{-1}, because the ^{79,81}Br and ^{35,37}Cl isotopic splittings were not resolved. This result is in agreement with an estimate of $\omega_e'' = 440$ cm^{-1} by Herzberg[4], based on an early study of two vacuum ultraviolet band systems of bromine chloride[5]

In the present work, we have recorded the $^3\Pi_{0^+} \leftrightarrow {}^1\Sigma^+$ band system of bromine chloride in absorption using equilibrium mixtures of bromine, chlorine and bromine chloride

Although the equilibrium

$$Br_2(g) + Cl_2(g) \rightleftharpoons 2BrCl(g); \quad \Delta H^\circ = 0$$

lies to the right hand side at all temperatures used in this work (294° < T < 690° K), with $K_{eq} = 6\ 5$ at 300° K, a difficulty arises from the visible absorption bands of small quantities of bromine in the equilibrium mixtures. Because the banded spectrum of bromine chloride lies in the same wavelength region and is not well developed at room temperature, this probably accounts for the negative results of previous searches for the bromine chloride bands In the present study, absorption caused by molecular bromine was minimized by using a large excess of chlorine (initial ($P_{\mathrm{Cl_2}}/P_{\mathrm{Br_2}}$) between 20 and 60) at total pressures near 700 mm of mercury; typical partial pressures of bromine chloride were thus about 20 mm of mercury The gaseous mixtures were contained in a uniformly heated 200 cm 'Pyrex' tube with 7 cm diameter 'Pyrex' windows sealed on The continuum from a 55 W quartz iodine lamp was used with a system of plane mirrors and lenses to give a path length of 600 cm for absorption. All gas mixtures were allowed to equilibrate overnight

The spectra were photographed with a 10μ slit in the first order of a grating spectrograph of inverse linear dispersion 40 Å mm^{-1}, the resolving power (10,000) was limited by the resolving power of the photographic emulsion Wavelength calibration was by means of a neon discharge tube The spectral range studied was 5000 Å to 7200 Å, which was covered by 'Panatomic *X*' and *I-N* emulsions

The absorption spectra of various mixtures of bromine and chlorine were examined at different temperatures At 294° K, the $^3\Pi_{\mathrm{ou}+}$—$^1\Sigma_g^+$ band system of chlorine[6] at 700 mm of mercury extended to about 5400 Å ($v'' \leqslant 2$). The spectrum of a similar pressure of chlorine mixed with 12 mm of bromine contained several new, rather weak bands, degraded towards the red, in the region 5400 Å to 5800 Å Bromine $^3\Pi_{\mathrm{ou}+}$—$^1\Sigma_g^+$ bands[7,8] were very weak under these conditions.

On increasing the temperature (up to 690° K), the spectrum of chlorine (700 mm of mercury) developed progressions in v' from higher values of v'' ($v'' \leqslant 5$), so that at the highest temperature the chlorine band system extended to about 6100 Å With a similar increase in temperature, the new band system from the chlorine+bromine mixtures was relatively more intense, and extended even further towards the infrared. About twenty-five additional bands extending to 7000 Å were observed with medium intensity The same system was observed with greater intensity at 690° K using a mixture of 700 mm chlorine with 35 mm bromine

Measurements of the wave-numbers of the heads of the new bands resulted in an identification with the same bromine chloride band system observed in emission from the combination of bromine and chlorine atoms[1] With the same vibrational numbering, short v' progressions from $6 \geqslant v'' \geqslant 0$ of the $^1\Sigma^+$ state were observed in the absorption spectrum. The (v', 0) progression was not particularly intense, and was difficult to identify at higher temperatures on account of overlapping by chlorine ($^3\Pi_{\mathrm{ou}+}$—$^1\Sigma_g^+$) bands and by bromine chloride continuum Bromine chloride heads near 6000 Å were quite sharp, but some other bromine chloride heads were diffuse on account of the finite Br 79/81 isotopic splittings, which were not resolved with the dispersion of our spectrograph Cl 35/37 isotopic splittings were observed for a number of bands, however. Table 1 shows the wavelengths of the band heads of the system bromine chlorine ($^3\Pi_{0+}$—$^1\Sigma^+$) observed in absorption and emission[1]. The agreement is good in view of the limited precision of measurements in the emission spectrograms

The termination of the bromine chloride band system at the $v''=0$ progression, followed by continuous absorption to shorter wavelengths, and the relative intensities of the $v''=0$ and $v''>0$ progressions, strongly suggests that the vibrational numbering of the upper state given in the earlier work[1] is correct In the absorption spectrum of bromine chloride, transitions were observed to vibrational levels with $v'=8$ and 9, which lie at 18,172 ± 5 cm^{-1} and 18,288 ± 5 cm^{-1}, respectively, above $v''=0$ of the $^1\Sigma^+$ state Because the dissociation limit for Br($^2P_{\frac{3}{2}}$) + Cl($P_{\frac{3}{2}}$) lies[1] 18,007 ± 50 cm^{-1} above $v''=0$, these observations show that the excited state dissociates to Br($^2P_{\frac{3}{2}}$) + Cl($^2P_{\frac{1}{2}}$) for which the dissociation limit is 18,888 cm^{-1} (ref 1) The earlier identification of the upper state[1] as $^3\Pi_{0+}$ is therefore confirmed

Table 1 BAND HEADS OF BrCl($^3\Pi_{0+} \longleftrightarrow {}^1\Sigma^+$)

6	6	6534	—
5	6	6608	6604
4	6	6685	6682
3	6	6771	6766

The band head analyses of the absorption and emission systems of bromine chloride ($^3\Pi_{0+}$—$^1\Sigma^+$) gave the same values for the vibrational constants, within the estimated limits of error. The mean values of all these data can be represented by the expressions

$$G''(v)(\mathrm{cm}^{-1}) = 443\ 5(v''+\tfrac{1}{2}) - 1\ 8(v''+\tfrac{1}{2})^2 \text{ for } 0 \leqslant v'' \leqslant 14$$

and

$$G'(v)(\mathrm{cm}^{-1}) = 16{,}705 + 239(v'+\tfrac{1}{2}) - 5\ 5(v'+\tfrac{1}{2})^2 - 0\ 08 (v'+\tfrac{1}{2})^3 \text{ for } 2 \leqslant v' \leqslant 9$$

The relatively large value for $\omega_e' y_e'$ is consistent with the expected maximum in the potential curve of the $^3\Pi_{0+}$ state of bromine chloride (compare the $^3\Pi_{0+}$ state of iodine chloride[9]) The observations of intense continuous absorption and unfavourable Franck–Condon transitions from $v''=0$ at 294° K also support the prediction of a potential maximum at an energy just above $v'=9$

The absorption spectrum of bromine chloride is currently under further study in this laboratory, using a Jarrell-Ash 3 4 metre Ebert spectrograph

Potassium Selective Microelectrodes with Precipitate in the Tip

THE thermodynamic analysis of physico-chemical processes in the living cell requires a knowledge of intracellular ionic activities. This problem has stimulated research into the design of special microelectrodes which are selectively sensitive to the different ions. This has been achieved by using either reversible, glass insulated, metal microelectrodes[1,2], or the so-called membrane electrodes[3]. The interphase potential of a metallic silver–silver chloride electrode, the most commonly used, is a function of the activity of chloride ions in the solution and its selectivity properties are determined by the presence of the silver chloride precipitate layer. In membrane electrode systems, selectivity depends on the ion exchange properties of the membrane material, and the transmembrane potential is a function of the ion activity ratio across the membrane for a particular ion. For the cations H^+, K^+ and Na^+, glass membrane electrodes[3] are usually used while silicone–rubber membranes packed with certain precipitates or ion-exchange substances are used for various anions[4].

In the course of experiments, it was noticed that, in certain conditions, even ordinary glass microelectrodes developed selectivity properties. The conditions in which this was observed were the following: a microelectrode in contact with the cell wall (cation-exchange phase) of *Nitella* cells[5,6] exhibited the characteristics of a K^+-electrode; the microelectrodes the tips of which were sealed with cellular materials maintained the potentials of the cell wall even after removal from the cell. This tip potential was a function of the sodium, a_{Na^+}, and potassium, a_{K^+}, ion activities, with a slight selectivity for K^+ rather than Na^+. After prolonged immersion in 3 molar potassium chloride solution (about a month) or after being held in air for a few hours, the microelectrode potential was seen to increase greatly because of a new phase forming in the tip, possibly a precipitate of potassium chloride from the saturated solution. Such microelectrodes were again selective for K^+ against Na^+ with a selectivity coefficient[7] (or permeability ratio) of 0.4.

These observations suggested that the usual microelectrodes might be converted into electrodes sensitive to selected ions by sealing their tips with an ion-exchange material which might be formed by precipitating a salt containing the particular ion. The formation of the precipitate inside the tip of the microelectrode leads to the distribution of ion activities between this newly created phase and the corresponding solutions contained inside and covering the outside surface of the microelectrode.

In the present work, the two reagents used to precipitate sparingly soluble potassium salts (K^+-precipitate) were nearly saturated solutions of sodium cobaltinitrite with a few drops of glacial acetic acid and dipicrylamine dissolved in 1 molar sodium hydroxide (according to IUPAC[8]). There are two principal steps in the manufacture of a K^+-sensitive microelectrode of the precipitate type. First, the tip of the microelectrode is filled with the potassium reagent, and, second, a precipitate of a potassium salt is formed inside the tip.

Glass microelectrodes with a tip diameter of about 1μ could be filled by microcapillary forces[9], the tip being inserted into the potassium reagent for 5–10 sec (or minutes if it was intended to fill the shank). Filling the microelectrode could also be accomplished quite readily by rotating (screwing) a fine glass capillary rod on the inside of the shank. To form the precipitate in the tip, the electrode was lowered into a 0.1 to 0.2 molar potassium chloride solution. This operation was viewed under a microscope. The microelectrode was then filled with 1 molar potassium chloride, using the standard ethanol boiling technique, to make contact with the precipitate from the inside. To obtain mechanically stable precipitates the temperature of the microelectrode, before boiling, should be kept at about 70° C for several hours.

A more convenient method of making the K^+-selective microelectrodes was to fill the shank with the K^+-precipitating reagent and then to make contact with this using a fine silver–silver chloride electrode. The actual precipitate was deposited as described. For experiments with plant cells it is not necessary to deposit the potassium precipitate before inserting the microelectrode into the cell because the tip fills with cell sap as soon as it is introduced into the vacuole (by turgor pressure).

The calibration of K^+ microelectrodes was carried out in pure potassium chloride and sodium chloride solutions in the range of 10^{-5} molar up to 1 molar. The method of making electrical measurements is described elsewhere[10]. It was found that the potential of the K^+ microelectrode (E_{K^+}) was a linear function of the logarithm of activity for the range 10^{-3} molar to 0.6 molar. The potential E_{K^+} could be expressed as $E_{K^+} = (RT/F)\ \ln\ (a_{K^+} + \alpha a_{Na^+})$. The best selectivity coefficient, α, achieved in the present work was 0.12. Because the activity of Na^+ in living cells is low the effect of these ions on the K^+ potential is quite small.

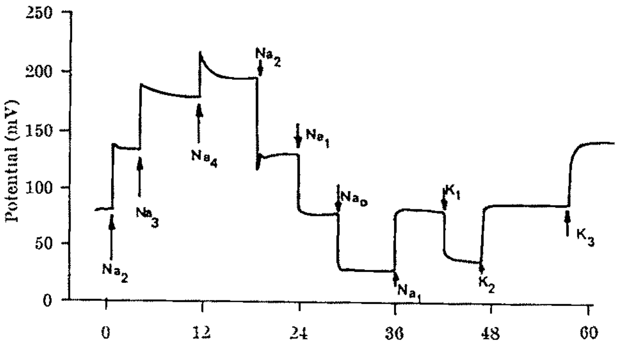

Fig 1. The potential of the K^+-selective microelectrode in potassium chloride and sodium chloride solutions of different concentrations (Na_2 refers to 10^{-2} molar sodium chloride, Na_1 to 10^{-1} molar sodium chloride, K_1 to 10^{-1} molar potassium chloride, etc.). The potential of the selective electrode is measured against a standard 3 molar potassium chloride filled microelectrode.

The sensitive area of these K^+ microelectrodes corresponds to the surface area of the open tip of ordinary microelectrodes. The advantage of this method of making cation sensitive microelectrodes is that no additional insulation of the shank is required. The resistance of the K^+ microelectrodes was found to be between 10^{10} and $3 \times 10^{10}\ \Omega$, a value which is considerably lower than the resistance of cation selective glass electrodes. The time response curves (Fig 1) suggest that there are two components of the electrode potential, a diffusion potential and a phase potential. The diffusion component of the total potential for Na^+ ions is much greater than that of K^+ ions, suggesting that the mobility of Na^+ ion is greater than that of K^+ ions. This is consistent with the idea that the K^+ ions are more strongly bound and thus potential determining. This is similar to the behaviour of K^+ glass selective microelectrodes[3].

Preliminary experiments have shown that the method of ion precipitation discussed can be extended to the manufacture of microelectrodes which are selectively sensitive to Ca^{++} and Na^+, and possibly to other ions.

Discrimination of Chemiluminescent Mixtures: the Chemiluminescencegram

A METHOD has been developed for the continuous measurement of the intensity of light obtained in oxychemiluminescence experiments with changes in the *p*H of the solutions The plot obtained, which has been called a chemiluminescencegram, permits differentiation between the various compounds in a mixture capable of showing chemiluminescence In our experiments, luminol was chosen to test the efficiency of the method

Luminol was first shown to be a mixture of five components and not a pure compound as is usually accepted Indeed luminol samples ('Fluka' for analysis, 'Schuchardt' for analysis, and a sample prepared by ourselves[1]) were chromatographed on Whatman No 3 paper with 0 1 normal sodium hydroxide as eluent and the luminol sample was prepared as a 10^{-2} molar aqueous solution with the stoichiometric amount of alkali added to produce the mono-salt The chromatogram which was developed in 135 min showed five bands, all of which gave strong fluorescence when illuminated with ultraviolet light (2537 Å) Band 1, 13 5 cm from the start, showed a blue fluorescence, band 2, 19 cm from the start, had a greenish fluorescence, band 3, 23 cm away, had a weak blue fluorescence, and band 4, a double band at 28 cm showed a greenish fluorescence Chromatography of 3-nitrophthalhydrazide, prepared according to the method of Huntress *et al* [2], on the other hand, showed only two bands which when illuminated with ultraviolet light produced no luminescence at all The components appeared as two dark bands This result indicates that the possibility that one or more of the bands which appeared on the luminol chromatogram were caused by 3-nitrophthalhydrazide which had not been reduced in the preparation procedure could be excluded

The five components of the luminol mixture were then separated chromatographically, but, unfortunately, they were not in sufficient quantities for their structures to be established Enough material was obtained, however, for us to carry out some oxychemiluminescence experiments The five luminol components were oxidized, using the standard procedure with hydrogen peroxide and potassium ferricyanide in alkaline solution, with simultaneous recording of the intensity of the light evolved

Out of the five components only four showed chemiluminescence, namely, bands 1, 2, 3 and 4 while band 5 produced no light at all The light versus time curves obtained from these four components were not similar to each other in these experiments or in experiments in which potassium ferricyanide was replaced by haemin It should be noted that the spectral distributions of the light in these experiments were also different, and the same was true for the ultraviolet absorption spectra of these components

The presence of four fluorescent, as well as chemiluminescent components, in what was considered to be a pure compound suggests another explanation for the chemiluminescence and fluorescence spectral distributions in different solvents reported[3] by White and Bussey Indeed the occurrence of the two emission peaks in their spectra might be caused by the presence of two distinct molecular species instead of two different kinds of excited state of the same molecule

The chemiluminescent components of the luminol mixture were distinguished on the chemiluminescencegram produced as follows A solution was prepared consisting of 10 ml of 10^{-2} molar luminol (the molecular weight of 5-amino-2,3-dihydro-1,4-phthalazinedione), 10 ml of 30 per cent sodium chloride, 10 ml of 1 normal sodium hydroxide, 5 ml 3 per cent hydrogen peroxide, 0 1 ml 10^{-3} molar manganese chloride, and 10 ml of water Carbon dioxide (400 ml /min) was bubbled through the solution (4 5 ml) which was in a tube placed in front of a photomultiplier connected to a recorder The temperature in these experiments is critical and should be carefully maintained between 8° and 14° C The recording obtained by this procedure was called a chemiluminescencegram and it is shown in Fig 1 ('Schuchardt' for analysis) Fig 2 was obtained from a luminol sample which we

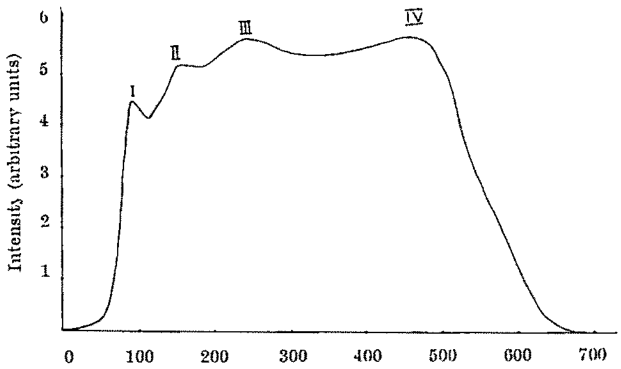

Fig 1 Chemiluminescencegram of luminol (commercial for analysis)

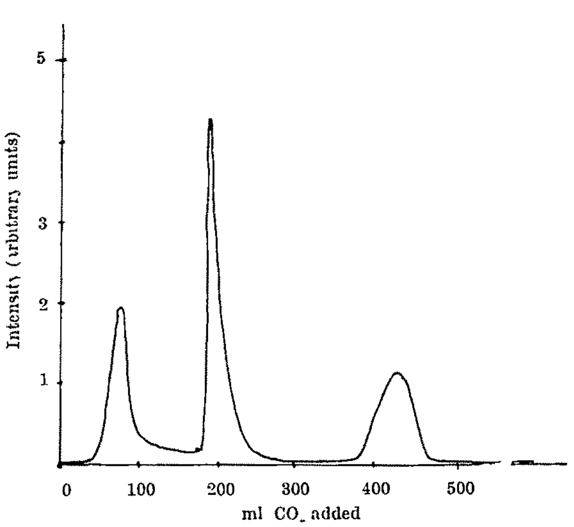

Fig 2 Chemiluminescencegram of luminol (sample prepared by ourselves)

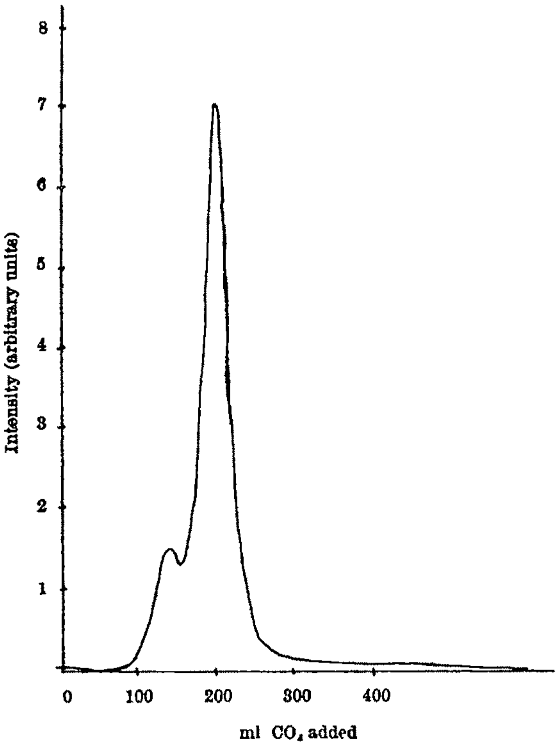

Fig. 3 Chemiluminescencegram of 3-nitrophthalhydrazide

prepared. The chromatographically separated components were then chemiluminescencegraphed and the peaks of the luminol chemiluminescencegram (Fig 1) were attributed No I to band 1, No. III to band 3, No. IV to band 2 and No II to band 4 of the chromatogram. A chemiluminescencegram of 3-nitrophthalhydrazide showed two peaks (Fig 3), indicating that both components of the mixture, established by chromatography, are chemiluminescent. Unsubstituted phthalhydrazide, however, showed the presence of several chemiluminescent components Finally, a similar method was used on a mixture of very pure rhodamine *B* and fluorescein and only two peaks were obtained.

This method, when carried out in strictly standardized conditions, not only offers a simple way of distinguishing the chemiluminescent components in a given mixture but also of identifying the known ones. Another characteristic of this process is that it offers a method of studying not only the light decay but also the light build-up, during chemiluminescence measurements Finally, it should be noted that the use of coloured reagents such as potassium ferricyanide and haemin is avoided, thus facilitating the study of the spectral distribution of chemiluminescence

The self-luminescence of luminol, which is a handicap in its use as a blood stain detector, has been overcome[4] by adding small amounts of 1-naphthol or 3-indazolinone-4-carboxylic acid to the luminol mixture used Adding 1-naphthol to a solution of luminol resulted in an almost complete disappearance of peak No I This indicates that the component corresponding to band 4 on the luminol chromatogram is responsible for the self-luminescence of luminol, and that luminol, free from this component, would be an adequate detector of blood stains without any addition being necessary, especially because the additives mentioned are known to cause an appreciable fall in the luminescence intensity

Preparative scale chromatography on a cellulose powder column resulted in a complete separation of band 1 but the other bands were only enriched. Fractional precipitation by the controlled neutralization of alkaline solutions of luminol seems more promising and we are working in this direction at present.

BIOCHEMISTRY

3-Methyl Histidine and Adult and Foetal Forms of Skeletal Muscle Myosin

RECENT independent investigations in this laboratory[1] and by Asatoor and Armstrong[2] have shown that 3-methyl histidine is a normal component of actin isolated from the skeletal muscle of a number of species In the case of rabbit actin, which has been most vigorously purified and intensively studied, approximately one histidine in nine is methylated and the 3-methyl histidine was found only in one of the peptide fractions isolated from tryptic digests of this protein[1].

On careful study of the acid hydrolysates of highly purified samples of the two other principal myofibrillar proteins, myosin and tropomyosin, using the Beckman system for amino-acid analysis of biological fluids, ninhydrin-positive material of identical elution rate to 3-methyl histidine could be detected only in myosin[1] Milligram quantities of this material were isolated from 15 g of myosin, and study of its properties and those of its dinitrophenyl and phenyl thiohydantoin derivatives confirmed that it was 3-methyl histidine This compound was present in myosin treated repeatedly with trichloroacetic acid to remove any non-covalently-bound peptide and amino-acid contaminants and in myosin purified by chromatography on DEAE cellulose[3] followed by fractionation with lithium chloride and ammonium sulphate The 3-methyl histidine was not a result of actin impurity in the myosin, for, although the former protein is present in very low amounts (probably < 1 per cent) in normal preparations, it could not be detected in the more highly purified myosin preparations when these were examined by the Ouchterlony procedure using antibody to rabbit actin raised in the fowl

Asatoor and Armstrong[2] also briefly mention the presence of small amounts of 3-methyl histidine in myosin but report that the amount decreased on purification. This has not been our experience 3-Methyl histidine was present only in the major components obtained on dissociation of the molecule by the alkali procedure of Gershman, Driezen and Stracher[4] and by succinylation[5] This evidence, and the fact that 3-methyl histidine is absent from light meromyosin fraction I but is present in heavy meromyosin and subfragment I (ref 1) in appreciably larger amounts relative to histidine than in myosin itself, strongly suggests that the residue is an integral part of the myosin molecule and not a result of traces of a protein impurity containing 3-methyl histidine

The amount of 3-methyl histidine estimated in rabbit skeletal muscle myosin varied from 1·44 to 1·88 moles per molecular weight of 500,000 Although there might be some variation in the 3-methyl histidine content of myosin from different rabbits, particularly in those of

Table 1 3-METHYL HISTIDINE CONTENT OF MYOSINS

3-Methyl histidine values calculated on the basis of the estimated ratio of 3-methyl histidine to histidine assuming myosin contains 14 4 residues of histidine per 10^5 g and has a molecular weight of 500,000

different strains, it is considered that the observed scatter arose more from the difficulty in obtaining an accurate estimation of this amino-acid in the conditions employed rather than from animal variation. The fact that some variation occurred between duplicate assays on the same myosin sample confirmed this view. The high ratio of histidine to 3-methyl histidine in myosin made accurate evaluation of the true area of the 3-methyl histidine peak very difficult, particularly if the histidine peak trailed to any extent The average 3-methyl histidine content of myosin purified by DEAE cellulose chromatography, and using only estimates made from those chromatographic runs in which there was clear separation of the two peaks, was 1 63 residues per mole (Table 1) This value incorporates more data and is slightly lower than the previously reported figure[1] of 1·71 residues per molecule of 500,000

In contrast with the results with myosin isolated from skeletal muscle of adult rabbit, ninhydrin-positive material corresponding to 3-methyl histidine could not be detected in significant amounts in acid hydrolysates of myosin isolated from skeletal muscle of the 28 day old foetus (Table 1) In some preparations a very small amount of material which has not been identified was eluted just after the normal position for 3-methyl histidine This material was not consistently observed, and so it was not considered to be a significant component The results indicate that in the rabbit there is little if any significant methylation of the histidine of myosin before birth and provides further evidence of structural differences between the foetal and adult forms of myosin[6,7]. The situation regarding methylation of the histidines in myosin seems to be different from that with actin where the foetal and adult forms appear to be very similar if not identical in 3-methyl histidine content[1].

Investigations in this laboratory on the rabbit[8] and by Severin on the duck[9] show that the enzyme system responsible for the *N*-methylation of the imidazole ring, as judged by the rise in anserine content of the non-protein fraction of muscle, does not become appreciably active until some days after birth. The difference between stages of development of the muscle at which occur the methylation of the histidine residues of actin and myosin raises some interesting questions about the biosynthesis of these proteins, the methylation systems involved and the metabolism of the myofibril as a whole

In view of the hypothesis put forward elsewhere[10] that the myosin from red muscle represents a form intermediate between that associated with fast white muscle and that present in foetal muscle, it was interesting to compare the 3-methyl histidine content of myosin isolated from cardiac and skeletal (longissimus dorsi) muscles of the adult rabbit 3-Methyl histidine was clearly present in the cardiac protein, and although the data are too limited for a firm conclusion the average values suggest that the 3-methyl histidine content of cardiac myosin is lower than that of myosin isolated from white skeletal muscle

The significance of the methylation of the histidines in the two myofibrillar proteins is not yet apparent, although the process is specific for a particular residue in actin and is probably so in myosin, as far as can be judged from our preliminary studies It is interesting, however, that the other well-documented example of a protein containing a methylated amino-acid, in this case lysine, is flagellin[11] which also has a contractile function. Methylation of the histidine would be significant for the structure of the polypeptide chain because it confers a non-polar character on the imidazole ring and destroys its hydrogen bonding potential. Histidine has often been shown to have a role in the specific biological activity of proteins; and although it is striking that actin and myosin, with their unique properties for interaction, both contain 3-methyl histidine, neither the presence nor absence of this residue in myosin seems to be essential for its ability to combine with actin to form a viscous complex dissociated by ATP, or to act as an ATPase. Foetal myosin combines with adult actin apparently as effectively as adult myosin although no careful comparative studies have been carried out Foetal myosin does, however, hydrolyse ATP more slowly than the adult form of the enzyme[6] Possibly the differences in the reactivity of its lysine residues and thiol groups to succinic anhydride and 5-5′-dithio *bis* (2-nitrobenzoic acid), respectively, and the quantum yield of the ultraviolet fluorescence of the tryptophan residues[7] have more bearing on the differences in enzyme activity of the adult and foetal forms of myosin

Methylation of specific histidines of the myosin molecule is an interesting but unexplained aspect of the modification of the myosin molecule which occurs during the transition from the foetal to the adult form of a contractile protein and may reflect an aspect of specialization in muscle development It is also possible, as has been suggested elsewhere[6], that myosin exists in isoenzyme forms, some of which contain 3-methyl histidine, and the complement of which in a given myosin preparation will be characteristic of the type of muscle from which the protein is isolated

Characterization and Rapid Labelling of Pituitary RNA

ALTHOUGH there is a great deal of evidence that hormones may directly influence the production of rapidly labelled RNA in many different tissues[1], some of it is equivocal[2]. Changes in rapidly labelled RNA of rat liver after the administration of hormones have been demonstrated by countercurrent distribution[3]. The interpretation of these changes is by no means clear, but cortisone increased the amount of rapidly labelled RNA in rat liver and decreased it in rabbit lymphocytes[4]. The pituitary is a source of many hormones, the secretion of which may be influenced by various factors, including the highly specific feed-back effects of the target gland hormones on trophic hormone synthesis. It may then be possible to examine the relationships between hormone action and rapidly labelled RNA production in this gland.

The RNA of young rat brain was easily labelled by direct injection of ^{3}H-orotic acid[5], but injection of radioactive orotic acid or uridine produced no labelling of the RNA from rat pituitaries. The RNA was successfully labelled by incubation of whole or halved glands in Eagle's medium[6] in the presence of ^{3}H-uridine.

Rats were killed by a blow on the head, were decapitated and the pituitaries were rapidly removed and the anterior lobes were placed in cold medium. Two glands are sufficient for each experiment, but between four and eight may be used. A sample of medium (1 ml.) (with streptomycin and penicillin) containing 500 μc. of ^{3}H-uridine, was used and the incubation at 37° C lasted 30 min for rapidly labelled RNA or up to 4 h for ribosomal RNA. The pituitaries were removed and broken down in 1 ml. of a cold mixture of 1 g of tri*iso*propylnaphthalene sulphonate, 6 g of 4-aminosalicylate, 1 g of NaCl, 100 ml. of water and 6 ml. of 2-butanol. The mixture was extracted with a mixture of phenol and cresol[7]. A second extraction was carried out in the presence of 0.5 molar NaCl and then the nucleic acids in the top phase were precipitated with two volumes of ethanol. Nucleic acids were dissolved in 0.1 molar sodium acetate and ribosomal and rapidly labelled RNA were precipitated with 4 molar NaCl. RNA was washed and purified as before and characterized by centrifugation in gradients of glycerol, sucrose, sulpholane with ethylurea or chloral[8].

The mean weight of the anterior pituitary gland from female hooded rats (4–6 months old) was 9.8 mg, whereas that from males of the same age was 7.0 mg. The content of RNA/mg of gland was the same in both sexes, 7.0–9.5 μg/mg and usually the final recovery measured by isotopic dilution of added rat liver RNA labelled with carbon-14 was about half this amount. The RNA of male pituitaries was more highly labelled in 30 min than that of females by ^{3}H-uridine and, using 500 μc./ml. of incubation medium, specific activities of 700–3,000 c.p.m./μg of RNA for males and 300–600 c.p.m./μg for females were obtained (32 per cent efficiency). Using 50 μc. of ^{3}H-uridine/ml. of incubation medium, the RNA from five male pituitaries had a mean activity of 3,700 counts/mg of pituitary while that from females had 505 counts/mg. When ^{3}H-guanosine (50 μc./ml. of incubation medium) was used for labelling, the RNA from male pituitaries had a mean of 5,130 counts/mg of pituitary, while the RNA from females had 2,120 counts/mg of pituitary.

Patterns of RNA from male and female pituitaries are shown in Fig. 1*a*–*d*.

The rates of sedimentation of the two ribosomal components are the same as those of ribosomal RNA from rat liver, judged by sedimentation of RNA in the presence of labelled (carbon-14) ribosomal RNA from rat liver and the radioactive pattern after incubating the gland with ^{14}C-uridine during 3.5 h followed by ^{3}H-uridine for 0.5 h, but even in these conditions a small proportion of carbon-14 label is found on the bottom of the gradient (Fig. 1*d*).

A large proportion of the rapidly labelled RNA is sedimented in the region between the 28*S* RNA and the base. This property is also characteristic of RNA from tumours[9], from young rat brain[5] and other tissues[10]. Still more radioactive RNA can be extracted from the base of the tube after the gradient solution has dripped out. This may be a separate fraction but accounts for a high proportion of the radioactive RNA. As postulated before[8], this material may result from the method of preparation using 4 molar NaCl to aggregate and precipitate ribosomal with rapidly labelled RNA. The nature of this rapidly labelled RNA with a high rate of sedimentation is at present being examined.

It is hoped to use this method to examine the effect of hormones and of target gland ablation on the RNA from the anterior pituitary and the hypothalamus.

This investigation was supported by grants from the Medical Research Council and the British Empire Cancer

Radiation Stimulated Incorporation of Thymidine into the DNA of Human Lymphocytes

TRITIATED thymidine is incorporated into both strands of DNA in HeLa cells which have been exposed to ultraviolet and ionizing radiation[1,2] This stimulated incorporation can occur in concentrations of hydroxyurea[3] which inhibit normal DNA synthesis

We have found that human blood lymphocytes are also stimulated by radiation to incorporate thymidine into their DNA This process which occurs in about 90 per cent of irradiated lymphocytes is not inhibited by hydroxyurea and occurs in the absence of phytohaemagglutinin or other mitogens It can be readily demonstrated after exposure to as little as 25 ergs/mm^2 of ultraviolet light, a dose which inactivates less than 30 per cent of the lymphocytes

The whole blood of young healthy donors was passed through a column packed with nylon fibres[4] and one drop was collected every 8 sec Plasma gel in the ratio of 1 3 was added to the filtered whole blood and the mixture allowed to settle for about 20 min Of the white blood cells present in the upper layer, 98–99 per cent were lymphocytes The cells were washed once in phosphate buffered saline, *p*H 7 2 (PBS), and immediately irradiated in open Petri dishes by a low pressure ultraviolet lamp delivering the bulk of its radiation at 2537 Å with an intensity of approximately 5 ergs/mm^2/sec The thickness of the cell suspension was about 1 mm and the concentration of cells for all irradiations was adjusted to 10^6/ml

For autoradiography the cell suspensions, after irradiation in PBS, were centrifuged for 5 min at 1,200 r p m (200*g*) and the pellet was resuspended in NCTC 199 medium supplemented with 20 per cent calf serum (Microbiological Associates, Maryland) and containing 10 μc /ml (6 7 c /mmole) of tritiated thymidine (New England Nuclear) The cells were kept in suspension during a 2 h incubation at 37° C in an atmosphere of 95 per cent air and 5 per cent carbon dioxide and then washed once in PBS containing 100 μg/ml of thymidine to block any further uptake of isotope After a further wash the cells were hypotonically treated in 1 per cent sodium citrate solution for 20 min Carnoy fixer was added to the cell suspension and the mixture was centrifuged The pellet was resuspended in fixer and slides were prepared Kodak *NTB*2 nuclear track emulsion was used for the autoradiographs Duplicate slides were treated with 1 mg/ml of DNase for 1 h at room temperature, *p*H 7 2 After 3 weeks at 4° C the slides were developed, stained with haematoxylin, mounted in 'Permount' and examined

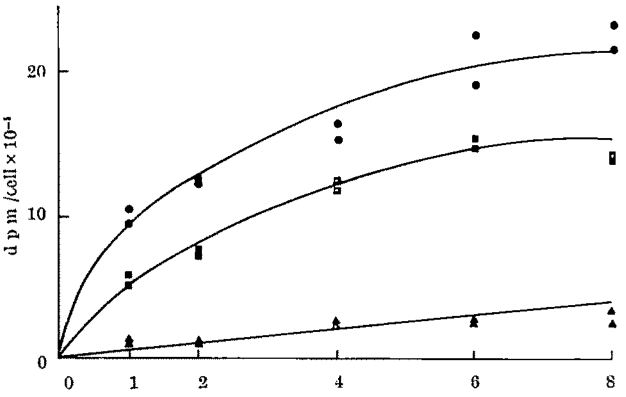

Fig 1 The kinetics of radiation-stimulated incorporation of thymidine into human lymphocytes The lymphocytes were exposed to ultraviolet radiation immediately after separation from whole blood, then incubated at 37° C in the presence of 10^{-3} molar hydroxyurea and 5 μc /ml of tritiated thymidine but without exposure to phytohaemagglutinin or other mitogens ●, 500 ergs/mm^2, ■, 25 ergs/mm^2, ▲, 0 ergs/mm^2

When liquid scintillation counting was used, 10^{-3} molar hydroxyurea was included in the incubation medium, to suppress the normal DNA synthesis occurring in a very small fraction of cells, in order to follow the stimulated incorporation Samples were removed from the culture bottles at various times, the number of cells per ml was determined and the samples were transferred to Millipore' filters Following washes with PBS, 5 per cent trichloroacetic acid and 95 per cent ethyl alcohol, the filters were completely dried at room temperature and placed cell side up in counting vials A sample of 10 ml of 'Premix *M*' (Packard, Illinois) in toluene was added to the vials and the activity counted in a Packard 'Tri-Carb' counter using a channel ratio method to determine efficiencies

Data for the survival were obtained by incubating the irradiated cells as before but using NCTC 109 medium Samples were removed from the cultures on the fifth day after irradiation and centrifuged The pellets were resuspended in PBS, the vital stain nigrosine (0 5 per cent, K and K Labs, Hollywood, California) added in a ratio of 1 4 and viable cells were counted Viable and dead cells were distinguished by their appearance under the phase contrast microscope viable cells showed clear cytoplasm with a soft-green nucleus, whereas dead cells showed black cytoplasm with a dark homogeneous nucleus

Table 1 shows that some 90 per cent of the lymphocytes incorporate tritiated thymidine into their DNA following doses of ultraviolet light of 25–400 ergs/mm^2 Less than 0 2 per cent of the cells incorporated thymidine in the absence of radiation This small fraction in normal DNA synthesis incorporates more than ten times as much thymidine as the stimulated cells in the 2 h incubation

Table 1 EFFECT OF ULTRAVIOLET LIGHT ON TRITIATED THYMIDINE INCORPORATION INTO HUMAN LYMPHOCYTES AND THEIR SURVIVAL

Ultraviolet dose (ergs/mm^2)	Percentage of labelled cells*	Fraction surviving after 5 days †
0	0 2	1 0‡
25	91	0 77
50	92	0 41
100	93	0 094
200	89	0 059
400	90	0 030

* Based on 500 cells at each dose The average number of grains per cell resulting from background was less than five, whereas the number in labelled cells varied between eleven and fifteen

† Each value is based on four haemocytometer readings

‡ Adjusted values based on a 60 per cent survival for the control culture

The incubation period was 2 h at a concentration of tritiated thymidine of 10 μc /ml (6 7 c /mmole) period and thus can be readily distinguished in autoradiographs from the radiation-stimulated cells.

The cells that had been stimulated by the radiation to incorporate thymidine could respond to phytohaemagglutinin when it was added to cultures of cells in fresh incubation medium by transforming and entering cell division.

The stimulated incorporation of thymidine after doses of ultraviolet radiation as determined by liquid scintillation counting is shown in Fig 1. Hydroxyurea, although it does not completely suppress the normal synthesis of DNA, as shown by the 0 ergs/mm^2 curve, has enabled us to follow the stimulated incorporation and also to correct the data obtained for the irradiated cells The incorporation of tritiated thymidine resulting from radiation alone occurs with no apparent delay following irradiation and is essentially complete after 6 h

Doses of ionizing radiation of between 1 and 16 krads also resulted in clearly demonstrable stimulated incorporation of thymidine The number of thymidine molecules incorporated per cell per rad following 1 krad in a 2 h incubation period is three—a number similar to the calculated number of single strand breaks per rad in the DNA of human lymphocytes

Peptide Inhibitors of the Renin–Angiotensin System

RENIN is said to split a leucyl–leucine bond in alpha 2 globulin substrate—angiotensinogen—to yield a decapeptide, angiotensin I. Angiotensin I is subsequently converted into an octapeptide, angiotensin II, by a converting enzyme contained in plasma Angiotensin II has a pressor activity We have studied the effects of synthetic peptides with a leucyl–leucine bond and their derivatives on the activity of renin in the formation of angiotensin The peptides were di-, tri-, tetra- and pentapeptides with leucyl–leucine bonds at the C-terminal end, in the middle position, at the N-terminal end or with one of the other structures as shown in Table 1

The experimental conditions were as follows Synthetic peptide (10 mg) was added to the reaction system containing 0 2 ml. of rabbit renin[1], 0 5 ml of plasma from a normal rabbit as substrate and 2·0 ml of 0 9 per cent sodium chloride solution The mixture was incubated at 37° C for 10 min and the reaction was then stopped by heating the mixture in a boiling water bath for 10 min Pressor activity of the supernatant was tested on the blood pressure of an anaesthetized, vagotomized rat treated with pentolinium An inhibitory effect of synthetic peptide was expressed as a ratio of the pressor activity of experimental and control samples

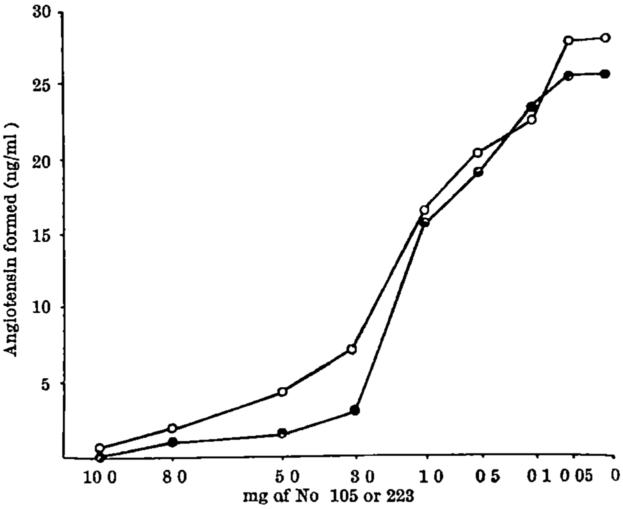

Fig 1 *In vitro* inhibition of the formation of angiotensin in the presence of varying amounts of synthetic peptides ○, No 105, Leu-Leu-Val-Tyr oMe, ●, No 223, Leu-Leu-Val-Phe oMe Rabbit plasma 0 3 ml., rabbit renin 0 05 ml , peptide in saline 2 75 ml ⟶Incubation *p*H 6 8, 37° C, 5 min

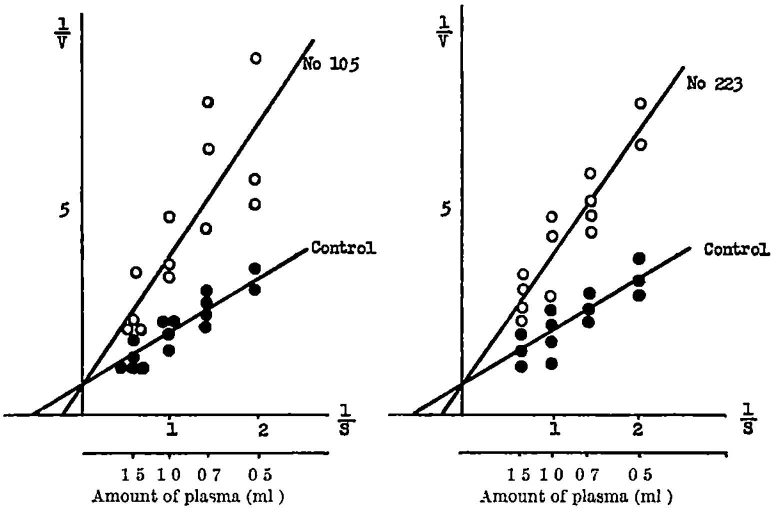

Fig 2 Inhibitory effects of synthetic peptides (No 105 (left) and 223 (right)) Lineweaver–Burk-type plots of the relationship between the reciprocals of substrate concentration and reaction velocity Control rabbit plasma 0 5, 0 7, 1 0, 1 5 ml , rabbit renin 0 05 ml and saline Experiment (with compound) rabbit plasma 0 5, 0 7, 1 0, 1 5 ml , rabbit renin 0 05 ml , compound (1 mg) in saline Total volume 3 1 ml , *p*H 6 8, 37° C, 5 min

Only the compounds Nos 105, 223, 263 and 242 among the synthetic peptides examined inhibited the formation of angiotensin in this *in vitro* system The ratios were 0 4–0 55 (average, 0 5) for No 105, 0–0 4 (average, 0 2) for No 223, 0 1–0 7 (average, 0 5) for No 263, and 0 4–0 7 (average, 0 5) for No 242 These four peptides were methyl or ethyl esters of Leu-Leu-Val-Tyr and Leu-Leu-Val-Phe, and they did not depress the blood pressure of the rat None of the other peptides inhibited the formation of angiotensin

Fig 1 shows the inhibitory effects of the varying amounts of synthetic peptides Nos 105 and 223 on the formation of angiotensin The pressor activity was expressed as angiotensin produced (ng) compared with synthetic α-angiotensin II amide (Ciba) About 25–30 ng of angiotensin was produced in 1 ml reaction mixture The formation of angiotensin decreased as the concentration of synthetic peptide was increased Fig 2 shows that the inhibitory effects of both Nos 105 and 223 were competitive according to the Lineweaver–Burk-type plot

It is not clear whether the peptides have an inhibitory effect on the renin alone or on both the renin and the converting enzyme The decrease of pressor response, however, indicates the inhibition of the enzyme hydrolysis of angiotensinogen, that is, it indicates the inhibition of renin activity, because the bioassay used demonstrates not only the amount of angiotensin II, but also the amount of angiotensin I formed in the reaction system So it is clear that the peptides might inhibit at least renin activity Furthermore, no decrease of the pressor response of synthetic α-angiotensin II amide in the rat was observed by adding the peptides, Nos 105 and 223, to the angiotensin injection This phenomenon suggests the peptides do not inhibit the rise of blood pressure caused by angiotensin

To summarize, methyl or ethyl esters of synthetic tetrapeptides, Leu-Leu-Val-Tyr and Leu-Leu-Val-Phe, acted as competitive inhibitors in the renin plasma reaction system used The chemical structures needed for the antagonistic activity are as follows (1) a leucyl–leucine bond at the N-terminal end in the tetrapeptide, (2) a leucyl–leucine bond with L-leucine (there was no inhibitory effect of the peptide with a leucyl–leucine bond with D-form instead of L), and (3) the presence of tyrosine or phenylalanine at the C-terminal end The last condition suggests that the phenyl group in the C-terminal amino-acid might be essential

We thank Dr H Bloch of the Ciba Pharmaceutical Institute for synthetic angiotensin II

Binding of Calcium and Strontium by Alginates

SODIUM alginates markedly inhibit the intestinal absorption of strontium in rats[1-4] and man[5,6] without an appreciable effect on calcium absorption so that they are of interest as possible therapeutic agents in cases of ingestion of strontium-90 Alginic acid is obtained from certain seaweeds and is a polymer of D-mannuronic acid and L-guluronic acid[7] joined by 1,4 linkages[8] It has been shown that guluronic-rich fractions of alginate are the most effective in reducing strontium absorption in rats *in vivo* and *in vitro*[4,9]

A measure of the calcium–strontium ion exchange reactions with various alginates has been obtained by calculating the selectivity coefficients for these ions[10]. In this study the formation constants of the polyuronic acids were found by the ion exchange resin procedure developed by Schubert[11,12], which assumes that the free metal ions in solution are neither hydrolysed nor polymerized[13], which is highly probable in the case of strontium and calcium The formation constant of an organo-metallic complex is given by

$$K_f = \frac{(K_d^0/K_d) - 1}{A^n}$$

where K_d^0 and K_d are the distribution coefficients of the metal between resin and solution in the absence and presence of the ligand respectively, A is the molar concentration of ligand and n is the number of moles of the ligand relative to the metal in the associated molecule[12] The distribution coefficient is defined as follows

$$K_d = \frac{\text{per cent metal in resin}}{\text{per cent metal in solution}} \times \frac{\text{vol solution}}{\text{wt resin}}$$

The data obtained by this method can be represented in several ways dependent on the manner in which A is expressed[14] In these experiments, concentration (A) is expressed in equivalents of uronic acid assuming an equivalent weight for sodium uronide of 198

The sodium uronides (0 01–0 001 equiv /l) were equilibrated with known weights of cation exchange resin saturated with sodium ('Dowex 50') in a solution containing 0 16 molar sodium ions and 10^{-7} molar calcium-45 or strontium-85 at 25° C and *p*H 7 2 Distribution coefficients were calculated from the radioactivity remaining in the supernatant The alginate derivatives were similar to those used previously for the study of inhibition of strontium uptake by an *in vitro* intestinal slice technique[4] and two to five different concentrations of uronide were used in each experiment L-Guluronic acid monomer was synthesized by a modification of the method of Fischer and Dorfel[7] and separated from other reduction products by chromatography on a column of 'Dowex-1'[15].

Table 1 FORMATION CONSTANTS OF THE CALCIUM AND STRONTIUM COMPLEXES OF A SERIES OF ALGINATE DERIVATIVES OF VARYING GULURONIC ACID CONTENTS AND DEGREES OF POLYMERIZATION (D P)

Percentage guluronic acid	D P	K_f Ca	K_f Sr	$\frac{K_f \text{ Sr}}{K_f \text{ Ca}}$
96	13	104	449	4 3
93	8	124	443	3 6
86	226	109	429	3 9
72	75	110	353	3 2
61	57	119	317	2 7
41	440	143	208	1 5
30	74	80	163	2 0

The results are presented in Table 1 together with guluronic acid content and number average degree of polymerization, determined as previously described[16] Monomeric L-guluronic acid has no detectable binding capacity for calcium or strontium ions in the experimental conditions By plotting log $(K_d^0/K_d - 1)$ against log A it was found that calcium and strontium ions formed a 1 1 complex with all the alginate fractions studied in the concentration ranges employed. The formation constants for strontium alginate are one and a half to four times greater than those for calcium alginate in these conditions Inhibition of intestinal cation transport by alginate should therefore have a greater effect on strontium than calcium absorption This series of formation constants seems to parallel the *in vitro* inhibition of strontium uptake by rat duodenal slices as shown by a similar series of alginate derivatives[4]

There is a good correlation between guluronic acid content and strontium–alginate formation constants which supports recent data[10] The calcium alginate formation constants do not appear to be related to guluronic acid content except that there is a marked increase from 30 per cent to 40 per cent guluronic acid The relative binding of strontium compared with calcium tends to increase with guluronic acid content As guluronic acid monomer has little or no specific cation binding capacity, this property of uronides is solely one of the polymer. The smallest unit exhibiting this binding is not known but must be between the degrees of polymerization of one and eight There is no evidence of the formation constants of the calcium and strontium polyuronide complexes depending on the degree of polymerization in this alginate series

No marked inhibitory effect of alginate on the intestinal absorption of other cations has been described Such investigations of the stability of an alginate–metal complex are useful in predicting the ligand's effectiveness in reducing the absorption of a given metal ion.

Influence of *p*H, Sodium and Calcium Ions on the d.c. Resistance of Black Egg Lecithin–Cholesterol Films

CONFORMATIONAL changes in coherent arrays of amphiphiles, such as phospholipids, are believed to be important in the function of biological membranes[1] Danielli and Davson[2] suggested that the bimolecular lipid leaflet comprised the basic structural unit in many natural membranes, but only recently has this fundamental structure become available for direct experimental investigation[3] These so-called black lipid films have d c resistances of 10^6–10^8 Ω cm^2 (refs. 4 and 5), but it is known that with certain preparations the resistance characteristics are markedly affected by the composition of the aqueous environment[5–7] This communication outlines some preliminary observations on the effects of *p*H, in the presence of sodium and calcium ions, on the d c resistance of egg lecithin–cholesterol films

The black membranes were prepared by smearing a solution of 10 mg of chromatographically pure egg lecithin and 10 mg of recrystallized cholesterol in 1 0 ml of *n*-decane across a 1 75 mm diameter hole bored in the wall of a 'Delrin' (Dupont de Nemours) vessel immersed in the appropriate aqueous phase Membrane resistances were determined by applying potentials up to 100 mV across silver–silver chloride electrodes situated in the inner and outer compartments and monitoring the current by a sensitive ammeter

In the first series of experiments, the aqueous phase comprised 0 1 normal sodium chloride to which various amounts of hydrochloric acid or sodium hydroxide were added to adjust the *p*H to values varying from 1 to 11 The exact value was measured before and after the determination of conductance using a standard *p*H meter Comparison experiments using solutions the *p*H of which was controlled by *tris* and phosphate buffers gave identical results In the second series of measurements, sodium chloride was replaced by 0 1 normal calcium chloride In a third series of experiments, the effect of varying concentrations of calcium chloride on membranes in 0 1 normal sodium chloride and known *p*H was investigated The rate of growth of black film varied with *p*H and the nature of the ion At both high and low *p*H in sodium chloride, film formation was rapid, but at *p*Hs greater than 9 in calcium chloride thinning was very slow and the film became rather rigid

In all cases d c resistance was found to be ohmic, at least up to applied potentials of 60 mV At higher potentials the current–voltage curve became convex towards the voltage axis, with the departure from linearity occurring at lower voltages at the extremes of *p*H The dielectric breakdown voltage was reduced to about 70 mV at high and low *p*H compared with about 150 mV at near neutrality Spot checks at 40 mV showed that the conductance increased in proportion to the growth of black film It was concluded from this that the conductance occurred through the bimolecular region

Curve *a* of Fig 1 shows the resistance obtained with films prepared in 0 1 normal sodium chloride at *p*Hs of between 0 and 9 All points are means of at least five determinations on two different phospholipid–cholesterol solutions Attempts to form films in solutions of higher *p*H were unsuccessful Replacement of sodium chloride by calcium chloride of the same normality completely altered the form of the resistance–*p*H curve (Fig 1, curve *b*) and black films formed at *p*Hs as high as 11 Addition of calcium chloride in the range 10^{-4} to 1 normal to an aqueous phase of 0 1 normal sodium chloride at various predetermined *p*Hs showed the membrane resistance to increase with the concentration of calcium chloride (Fig 2) It is particularly interesting to note that at *p*H 10 and 11 the presence of only 0 001 normal calcium

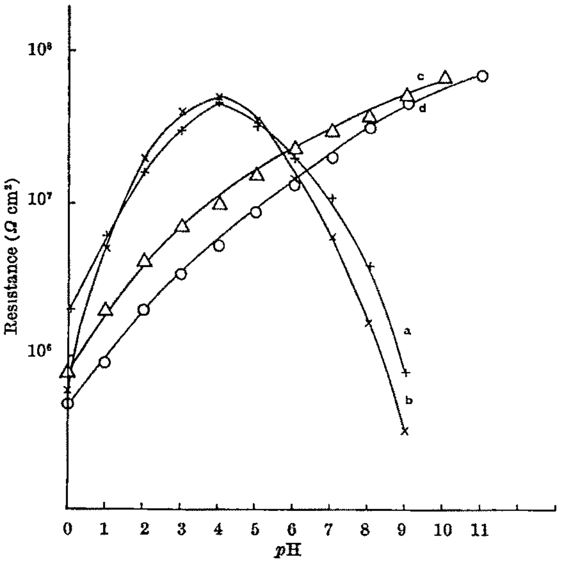

Fig 1 Resistance as a function of *p*H in 0 1 normal sodium chloride (×, +) and calcium chloride (△, ○) (Applied Science Egg Lecithin, General Biochemicals Egg Lecithin)

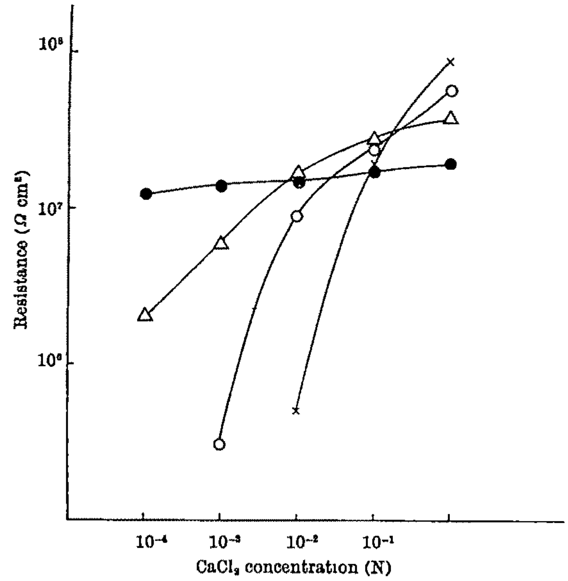

Fig 2 Resistance as a function of concentration of calcium chloride in 0 1 normal sodium chloride at various *p*Hs (Applied Science Egg Lecithin) ●, *p*H 6–4, △, *p*H 9, ○, *p*H 10, ×, *p*H 11

chloride was sufficient to enable films to be prepared whereas in the absence of calcium chloride complete black films could not be formed.

These results show that there is a striking difference in the resistance characteristics of lecithin–cholesterol films formed in the presence of sodium and calcium ions, and that when only sodium is present the resistance–*p*H curve passes through a maximum It is still only possible to speculate on the factors responsible for these observations Recent monolayer studies with egg lecithin have shown that exchange of calcium ions for sodium ions in the aqueous subphase produces considerable changes in both surface potential and pressure–area curves[8] These changes are attributed to the ability of calcium ions but not sodium ions to form bridge linkages between neighbouring phosphatidyl choline head groups A similar mechanism probably plays some part in the resistance changes observed with bilayers Ionization of the zwitterionic phosphatidyl choline head groups at the extremes of *p*H would tend to open the lattice and increase its permeability to ions, but at high *p*H, in the presence of calcium, this expansion is prevented by chelation

This investigation was supported in part by the US National Institutes of Health and the US National Aeronautics and Space Administration One of us (A G) acknowledges the award of a Dunstan Fellowship

MICROBIOLOGY

Transducing Phage for *Pseudomonas putida*

The extensive biochemical knowledge of various *Pseudomonas* species[1] would be considerably enhanced if genetic analysis was possible in these organisms Conjugation and transduction have both been demonstrated for *P. aeruginosa*[2,3], but, despite apparently many other attempts, only recently has a transducing phage been characterized for *P putida*[4]

This communication describes the isolation of a transducing phage for *P putida* which seems to be different from the phage *pf*16 described by Gunsalus and his colleagues Ten strains of *P. putida* were provided by Professor A Rorsch (Rijswijk, The Netherlands) These were isolated from soil and are all characterized by the ability to use atropine as a sole carbon source The media and cultural techniques used in this work are the same as those described in publications from this laboratory on *P aeruginosa* phages[5] All cultures were grown at 30° C.

Preliminary work (unpublished results of B W Holloway and J Niblack) had shown that, in a limited range of strains, lysogeny could not be detected in *P putida*, and so we tried to isolate phages for *P putida* from sewage by the standard techniques One such phage was isolated; this has been called *PP*1 and has been characterized in the following ways

As isolated, *PP*1 gives indistinct hazy plaques when plated on *P putida PMBL-4Bl* A clear plaque variant (*PP*1*C*) occurs at a frequency of about 1/1,000 turbid plaques We have not been able to propagate the turbid plaque form to titres greater than 10^6/ml and all work has been carried out with the clear plaque variant. Plaques on *PMBL-4Bl* are 2–3 mm in diameter with a distinct edge and a slightly hazy interior because of the growth within each plaque of individual small bacterial colonies Such colonies have been isolated and are resistant to *PP*1*C* but are not lysogenic Phage adsorption is usually 80–90 per cent with no apparent dependence on the growth phase of the bacterium The burst size is about 90 with a latent period of 25–30 min The phage is comparatively resistant to ultraviolet irradiation, showing linear inactivation, with a 2 log reduction of infectious particles at a dose of 3,400 ergs/mm^2

Propagation of the phage has been best achieved by the layer agar technique For reasons which are not yet clear, the highest titres of phage achieved by this method have only been about 2×10^9/ ml and are usually lower than this In the preparation of transducing phage, the input of phage to the layers is critical and best transducing titres have been obtained where the plaques are just confluent after overnight incubation The phage has a limited host range, strain *PMBL-4Bl* being the only sensitive strain among fourteen strains of *P putida* so far tested In addition, *PP*1 did not plaque on any of eleven strains of *P fluorescens* tested Phage *pf*16[4] does not form plaques on any of these strains of *P putida*

*PP*1*C* is a general transducing phage This was demonstrated as follows an overnight broth culture of a recipient auxotroph was inoculated into fresh broth and grown until it was in exponential phase It was then centrifuged, resuspended in calcium (0 01 molar) saline and infected at a multiplicity less than 0 1 with phage grown on the prototrophic parent strain After 20 min adsorption at 30° C, the culture was centrifuged, resuspended in saline, and 0 2 ml aliquots were plated on to minimal medium

In these conditions, transduction occurs at a frequency of about 10^{-6}/plaque forming particle and 10^{-7}/recipient bacterium The low multiplicity of infection is essential for reproducible and workable levels of transduction for at higher multiplicities of infection the lytic action of *PP*1 evidently interferes with the recovery of transductants Transduction has been shown for a variety of auxotropic markers including the requirements for tryptophan, isoleucine plus valine, leucine and methionine Transduction does not occur when the recipient is made phage resistant (presumably a non-adsorbing mutant), or if the phage is propagated on the same auxotrophic strain used as the recipient The transduced colonies are still sensitive to the phage Transduction frequency increases by a factor of 3–5 when the phage is irradiated with ultraviolet light (2,500 ergs/mm^2) before adsorption

Phages active on *P putida* are much rarer than those plating on *P aeruginosa*, either as isolates from sewage or derived from lysogenic strains Transducing phages are usually not virulent and it is likely that phages such as *PP*1 or *pf*16 are not virulent or intemperate but are non-lysogenizing forms of temperate phages

We thank Miss Helen Barton for technical assistance This work was supported by a grant from the Australian Research Grants Committee One of us (P v d P) was supported by a NATO grant

IMMUNOLOGY

Neonatal Splenectomy : Absence of Runting in Mice

Kalpaktsoglou, Yunis and Good[1] recently reported that early splenectomy of mice can cause a runting and wasting syndrome similar to that associated with neonatal thymectomy The importance of this finding to our current concepts of the development of immunological competence was stressed, as were the clinical implications for a variety of haematological diseases and for resistance to extracellular pathogens Experiments performed several years ago in our laboratory (unpublished work) and others[2] had failed to detect such effects, so we felt it essential to re-investigate this question to determine whether the newer findings were generally applicable

We used mice of strains *C57BL6/JAu*, $C_3H/HeAu$, C_3H/Bi and *BALB/CAu* as well as the F_1 hybrid *BALB/C* × *C57BL/6*, which were splenectomized within a few hours of birth Mice were cooled on ice blocks, an incision was made in the left lateral body wall, the spleen was removed with curved forceps and the wound was closed with a single stitch Mice were kept warm for a few minutes after splenectomy before returning them to their mothers Unoperated mice served as controls in each litter Operative mortality was negligible once the procedure had been mastered Some animals were lost in the first few days following operation, because of post-operative neglect and cannibalism by the mother (Table 1)

Table 1 EFFECT OF NEONATAL SPLENECTOMY ON GROWTH AND SURVIVAL IN MICE

Total	18	Operated	68	52	50
		Unoperated	54	50	48

Table 2 BODY WEIGHTS OF EXPERIMENTAL ANIMALS AT AUTOPSY (8 WEEKS)

	Females* No	Females* Weight	Males No	Males Weight
Operated	19	19 9 g	15	23 6 g
Unoperated	17	19 8 g	21	23 3 g

* Excludes pregnant females

Animals were examined at regular intervals before autopsy at 8 weeks old The results are presented in Table 1 Death after the immediate post-operative period was found to be minimal (4 per cent) in both the operated and control groups Runting was not observed (Table 2), the mean body weights of control and unoperated animals did not differ significantly, and there were no signs of wasting disease

These results are in sharp contrast to those of Kalpaktsoglou *et al* [1], who reported a mortality of 67 4 per cent which occurred primarily between the third and fourth week of life following a runting with an onset between the twelfth and sixteenth day Why these differences between experiments should exist is not clear It is, of course, known that runting may vary with laboratory conditions, for example, neonatal thymectomy fails to cause runting in germ-free animals[3,4] On the other hand, studies with mutant mice indicate that congenital absence of the spleen does not diminish antibody titres obtained in response to immunization with *Pasteurella pneumotropica*[5], and animals without spleens can survive and breed readily[6,7] Because the experiments of Kalpaktsoglou *et al* [1] offer no sham-operated control animals, one may wonder whether the observed runting and mortality might be caused by a non-specific effect of the operation, performed, after all, at a time when the immune system of the animal is not yet well established. Whatever the cause for the discrepancy, it is clear that it would be premature to generalize about the essential role of the spleen in murine post-natal survival

Herpesvirus Infection of Human Mesodermal Tissue (Cornea) detected by Electron Microscopy

Herpesvirus hominis (herpes simplex virus) usually infects tissues of ectodermal origin, particularly skin, mucous membranes and the central nervous system Viral replication has been observed in mesodermal cells (principally leucocytes) in experimentally infected rabbits[1] and mice[2] and in tissue cultures of human leucocytes[3] and embryonic fibroblasts[4]. There has been little evidence, however, that infection of mesodermal cells plays a part in primary or recurrent human infections.

Herpetic infections of one commonly affected site in man, the cornea, frequently lead to pathological changes in the mesodermally derived stroma[5]. In corneal herpes, the virus can be easily isolated from the typical dendritic lesions in epithelium, but it is rarely recovered from eyes with chronic stromal herpetic keratitis[6]. For this reason it has been assumed that deep herpetic keratitis is a form of host response which does not depend on direct viral infection of the corneal stroma.

We have observed herpesvirus in the stroma of five corneas which were obtained at surgery from patients with chronic herpetic keratitis (Table 1). Two were the originally diseased tissue (*A* and *B*1); three others were corneal grafts which had been in place for 32 days (*B*2), 8 months (*C*), and 14 months (*D*), respectively. For electron microscopy, portions of all five corneas were fixed with cold 3 per cent glutaraldehyde in a 0·067 molar cacodylate buffer, and after 4 h–3 weeks they were post-fixed with 1 per cent osmic tetraoxide in a phosphate buffer. Specimens were embedded in 'Epon' and thin sections were cut for electron microscopy.

Particles resembling herpesvirus were found in the stromal layers of all five corneas. These particles consisted of polygonal, electron-dense shells (capsids) about 70 mμ in diameter (Fig. 1). Some of the capsids contained a mass of electron-dense material (nucleoid), others seemed to be empty. Still others, seen in the vicinity of intact cells or within cytoplasmic vacuoles, were surrounded by a membrane corresponding to the viral envelope (Fig. 1 inset). These naked and enveloped particles were identical with the herpesvirus particles which were observed by us in experimentally infected rabbit corneas which had been prepared in the same way[7].

Viral particles were seen in the corneal stroma in intimate association with intact cells (Fig. 1) or as aggregates mixed with unidentified debris. In four corneas, intact cells were found with capsids in their nuclei and with enveloped particles outside the cell membrane or within the cell vacuoles. In three specimens (*B*1, *B*2 and *C*), there were large masses of virus particles between the collagen lamellae of the cornea. Like the intact infected cells, these masses of particles occurred in the deepest layers of the cornea, distant from the surface epithelium. In one specimen (*B*2), virus particles were seen also within cytoplasmic vacuoles of the polymorphonuclear leucocytes, probably as a result of phagocytosis.

In four of the five corneal specimens which were examined (*A*, *B*1, *C* and *D*), many cells in the corneal stroma contained virus capsids within their nuclei (Fig. 1). Sequential studies of herpesvirus replication have shown that virus particles entering a cell are enclosed in a cytoplasmic vacuole[8], that the viral envelope is removed[9], and that naked particles can be found free in the cytoplasm but not in the nucleus during the early phase of infection[9]. As the growth cycle continues, newly formed virus capsids appear in the nuclei of infected cells shortly before infectivity increases[8]. In our specimens, the presence of virus particles in nuclei indicates that virus replication had indeed taken place within cells in the stroma of these corneas. The absence of viral particles in the nuclei of cells in specimen *B*2 could have been a result of treatment with 5′ iodo-2-deoxyuridine which is known to inhibit herpesvirus replication. The formation of enveloped particles outside the cell membrane and in cytoplasmic vacuoles of cells containing nuclear particles indicates that the final step in the formation of fully mature virus particles had taken place[8].

Table 1. HERPESVIRUS IN HUMAN CORNEAS

Specimen	Herpesvirus particles by electron microscopy	Herpesvirus isolation attempts	
		Corneal swab	Minced tissues
A	+	Neg.	N.D.
*B*1	+	Pos.†	Neg.
*B*2*	+	Neg.	Neg.
*C**	+	N.D.	N.D.
*D**	+	N.D.	N.D.

* Previously transplanted tissue.

† Eight months before the tissue specimen was obtained.

N.D., not done.

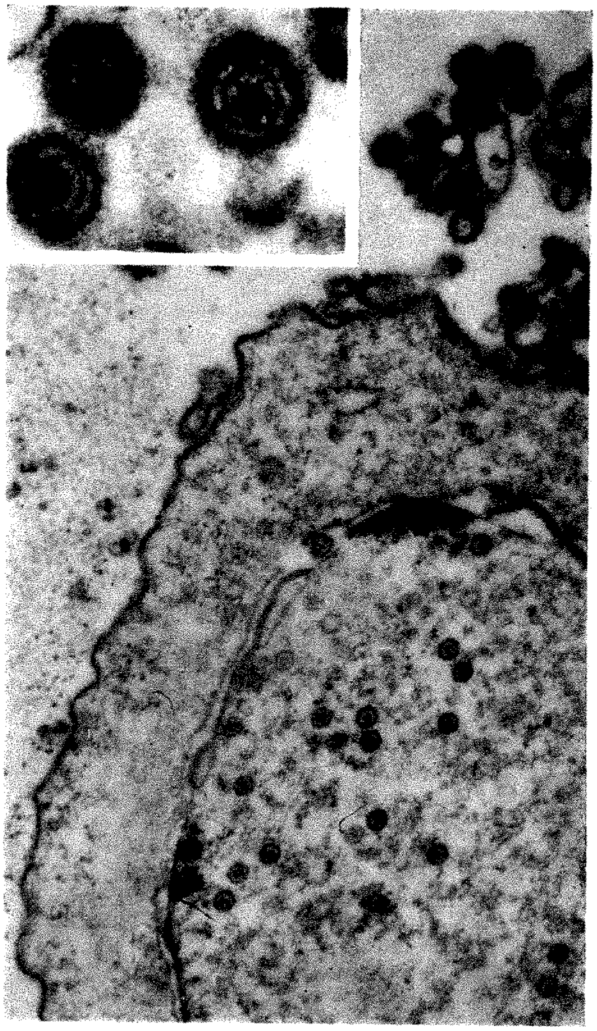

Fig. 1. Corneal stromal cell in specimen *B*1. There are numerous naked herpesvirus particles in nucleus (lower right), and particles with envelopes outside cell (top). Altered corneal collagen is at left of cell (×35,000). Inset: extracellular particles from same specimen with dense central nucleoid surrounded by capsid and outer envelope (×91,000).

Attempts to isolate herpesvirus before surgery were made by swabbing the cornea with a cotton tipped applicator which was then immersed in maintenance media with 2 per cent foetal calf serum (Table 1). Portions of two corneas (*B*1 and *B*2) were minced in the same media. Media surrounding the swab or the minced tissue were inoculated into Maben cells. A single isolate of herpesvirus was obtained from patient *B* during an episode of epithelial (dendritic) keratitis, 8 months before surgery. Swabs of cornea *A*, *B*1 and *B*2 immediately before surgery failed to yield virus, as did the minced tissue from specimens *B*1 and *B*2.

The failure to recover virus in cell cultures of corneal material from eyes not showing typical epithelial lesions confirms past experience[6]. The following are among possible explanations for this inability to isolate virus from corneas with herpes-virus particles.

(1) Only a few cells at a time might have been producing infective virus, and this process could have been limited to a small part of the cornea; this might have led to an accumulation of virus particles even though relatively little infective virus was present. The cornea, even in diseased states, is avascular and dense, and the removal of particulate matter such as virus particles could be a slow, inefficient process. Because herpesvirus is thermolabile[3], the particles seen in our specimens could have accumulated for many days and would have lost infectivity while retaining their morphological identity. (2) Only a small proportion of particles seen in section were structurally "complete". It has been suggested that "complete" particles are more infective than "naked" particles, but this has not been confirmed[9]. (3) These virus particles might belong to another member of the herpesvirus group, for example, varicella-zoster virus or cytomegalovirus. At some time in the course of their disease, however, all these patients had the typical dendritic corneal lesions commonly associated with herpes simplex, and they all exhibited clinical signs characteristic of chronic herpetic keratitis.

The exact identity of the cells which were infected with herpesvirus seen in the stroma of these corneas could not be established with certainty. Following experimental infection with herpesvirus, the stroma of rabbit corneas might contain regenerating keratocytes, fibroblasts, polymorphonuclear leucocytes, lymphocytes, plasma cells and macrophages (histiocytes)[10]. Cells which were infected with herpesvirus in the human corneas in this study had only one nucleus, little organized endoplasmic reticulum and few specialized organelles. They were clearly neither polymorphonuclear leucocytes nor lymphocytes. Probably derived from embryonic mesoderm[11], they could well have been fibroblasts or keratocytes.

The presence of herpesvirus in corneal stromal cells indicates that herpesvirus proliferates in mesodermal as well as ectodermal cells. Infection of connective tissue cells could also play a part in the pathogenesis of herpes infections at other sites, and could be concerned with the latency of the virus between recurrences of clinical activity.

We thank Drs Phillips Thygeson and Ernest Jawetz for their advice and encouragement. This investigation was supported in part by Public Health Service research grants from the US National Institute for Neurological Diseases and Blindness, and by a career development award to Dr Dawson.

Failure to detect Interferon in the Urine of Persons with Virus Infections

WHEN rabbits or mice are inoculated intravenously with interferon or with an inducer of interferon formation, interferon appears in their urine[1-6]. Indeed, with rabbits, appreciably higher concentrations can be found at the same time in the urine than in the serum[2-4]. In contrast, we report here two studies in which interferon was not detected in urine from humans with viral infections.

One study which has been summarized elsewhere[7] involved children with mumps, measles or chicken-pox. The urine was collected from three groups of seven or nine children with each disease, from the first day when the rash appeared or the salivary gland swelled, for 4 days. A sample of urine which was collected from each child during each period of approximately 8 h was treated at *p*H 2 for 5 days at 4° C and was then returned to *p*H 7 and assayed for interferon. Serial dilutions were made in Eagle's medium from an initial one in four dilution, and these were added to groups of three tube cultures of human embryo lung cells. After incubation overnight at 37° C, the tubes were drained, rinsed twice with fresh medium and challenged with one hundred infecting doses of HGP rhinovirus. After 3 days at 33° C, the cytopathic effect (CPE) was scored on the conventional 1–4 scale, and the 50 per cent CPE-inhibition endpoint was determined graphically. A laboratory reference human interferon preparation was included in all assays as a control. No interferon was detected in any of the urine samples. Some of the urine sample from two children within each of the groups was then concentrated seven to nine times by pressure dialysis in 'Visking' tubing, but still no interferon was found on assay. Because of the theoretical possibility that the acidification or pressure dialysis treatments had caused losses of interferon, a number of urine samples were assayed without such treatments, but again with negative results. We also found that small amounts of human leucocyte interferon which were added to normal urine were stable at *p*H 2 and on pressure dialysis.

Because blood samples were not collected, it is not known whether interferon was present in the blood of the children during the period of urine collection. Petralli, Merigan and Wilbur[8], however, vaccinated children with live measles virus and found interferon in their blood 7–11 days later. In our investigation, urine was collected from three children with measles from the onset of prodromal symptoms, that is, about 10 days after infection, until 4 days after the appearance of the rash. By analogy, it seems likely that interferon was present in the blood during at least part of this time, but none was detected even in concentrated urine samples.

Merigan[9] found very small amounts of interferon in concentrated urine samples from children with mumps.

Wheelock and Sibley[10] found interferon in the blood of subjects vaccinated with yellow fever virus. We therefore subcutaneously vaccinated six volunteers with the 17*D* strain of yellow fever virus (10^4 mouse 50 per cent lethal doses). Serum and urine samples which were collected on days 0, 4, 5, 6, 7, 8 and 36 were assayed for virus, interferon and antibody. All volunteers showed a transient viraemia between the fourth and seventh day after vaccination, and all had a rise in antibody titre on day 36. Interferon was found in the sera of three volunteers at the time of the peak of viraemia or a day after. The maximum levels were 4, 10 and 1 units of interferon per ml., but no interferon was found in any of the urine samples. During the course of this work, Dr A. Quercioli of the University of Siena informed us that he also was unable to detect interferon in the urine of volunteers who were vaccinated with yellow fever virus.

From collaborative studies with workers in six different laboratories currently studying human interferon, we believe that our assay for human interferon is at least of average sensitivity. Our results, together with those of Merigan and Quercioli, suggest therefore that subjects infected with mumps, measles, chicken-pox and 17*D* yellow fever viruses do not excrete interferon in their urine in amounts which are readily detectable by present methods. In contrast, Soloviev[11] reported that interferon was present in urine from patients who were infected with influenza *A*2 virus in concentrations higher than those in the serum.

We thank all the general practitioners and volunteers who co-operated in this study.

CYTOLOGY

New Simple Method of Micrurgy on Living Cells

A SIMPLE method has been developed whereby micrurgy on living cells such as nuclear transplantation and cytoplasmic injection in amoebae can be performed with greater ease and rapidity. The present method differs from those used currently[1-4] in that the need for a micro-hook to hold cells and the use of mineral oil (liquid paraffin) to prevent the evaporation of culture medium are eliminated. This is done by placing the cells on an agar surface. When the excess medium surrounding the cells is withdrawn, they remain firmly attached during operations. The agar gel apparently replaces the medium that evaporates, and there is no damage to the cells during the period required for micrurgy. Thus, for example, nuclei are transplanted between amoebae in open drops with a micro-probe alone.

This principle can be applied to both the original hanging drop method[1-3] and the modified slide method[4]. For preparation, 0.6 per cent agar in the cell culture medium is boiled, filtered and poured while hot onto clean glass slides or coverslips (agar with different purities and at different concentrations was tried, but ordinary bacteriological, non-nutrient agar obtained from Fisher Scientific Co. was found to be most suitable). As soon as the agar cools and gelates, cells can be placed on it and are ready for operations.

No hooks are used, and so it is necessary to place cells in desired positions beforehand. For example, the donor and recipient cells for nuclear transplantation are placed side by side before withdrawing the excess medium. After this, the cells cannot move and different ones can be easily distinguished by their relative positions during and after operations.

With a good objective that has a relatively long working distance, of which there are several makes available, the slide method is preferred to the coverslip method. In the slide method, no inversion of the operation stage is necessary and there is more freedom of movement both with the micro-tool and the slide. For example, using a circular rotating microscope stage, the direction of the arrangement of cells being operated can be easily changed up to 180 degrees. With the slide method, the micro-probe is bent downwards and applied to the cells from above[4].

The advantages of this new method are obvious and manifold: first, there is no hook to make and use, thus eliminating the most troublesome portion of the micrurgical work. As a result, operations can be performed with much greater ease and rapidity than with other methods. For example, as many as 200 amoebae can be easily enucleated in an hour and thirty nuclear transplantations can be carried out during the same period in optimal conditions (compare ref. 3).

While the agar-coated slides were designed primarily for micrurgy on amoebae, they were also found useful in immobilizing other motile cells such as *Tetrahymena* and *Paramecium* for microscopic examination and manipulation of these cells.

PATHOLOGY

Sebaceous Gland Activity in Breast Cancer

A NUMBER of observations suggest that human breast cancer develops under hormonal influence. Several such observations include (*a*) breast cancer is predominantly a disease of women, (*b*) the administration of oestrogenic materials produces breast tumours in experimental animals[1], (*c*) the course of breast cancer is influenced by ablative endocrine procedures or by the administration of exogenous hormones in both humans and experimental animals[2-4], and (*d*) the length of the menstruating years and the number of pregnancies affect the frequency of the disease in any given population[5,6].

The physiological role of oestrogens in breast cancer has not been clearly elucidated, although this has been examined in some detail. Measurements of the urinary excretion of oestrogen metabolites in women with breast cancer as compared with age-matched control populations of healthy and ill females have revealed no uniformly significant differences[7,8].

Studies of total urinary 17-ketosteroids, as well as androsterone and aetiocholanolone, have not demonstrated any significant abnormal pattern in women with breast cancer[9-11]. Bulbrook *et al.* have demonstrated that the clinical response to ablative surgery was predictable from the concentrations of urinary aetiocholanolone and 17-

hydroxycorticoids, arranged as a statistical phenomenon and termed the "discriminant" The higher the urinary values of aetiocholanolone in relation to hydroxycorticosteroid levels, the better the response rate to the ablative endocrine surgery The "discriminant" may also predict the clinical course of a woman with early breast cancer

Study of certain tissue and organs known to be influenced by hormonal factors may reveal biological information relevant to the problem of breast cancer The sebaceous gland is such an organ

The development and activity of the sebaceous glands of the skin are primarily under the direct influence of androgen[12] In prepuberal subjects, administration of as little as 5 mg of methyltestosterone daily will stimulate the sebaceous glands[12] This change can be observed in histological sections as well as in an increase in sebum production, a quantitative measurement which is an accurate indicator of sebaceous gland function[2] Marked development of the sebaceous gland occurs in both sexes at puberty, although throughout the adult years significantly higher concentrations of sebum are noted in men than in women In the female, sebaceous gland activity declines significantly after menopause In men such a fall in sebum production does not occur, rather there is a very gradual decline[13]. Bilateral orchiectomy in the elderly male, however, results in a marked fall in sebaceous gland secretion[4]

The administration of oestrogen will result in a reduction in sebaceous gland activity This effect, even from very large doses of oestrogen, is prevented by the concomitant administration of disproportionately small amounts of androgen, indicating that there is no target-site antagonism between oestrogen and androgen[12] Progesterone, in physiological amounts, does not stimulate the sebaceous gland[15] The role of corticosteroids has not been clearly defined, but there is evidence to suggest that they are needed in a permissive role to allow for sebaceous gland response to androgenic stimulation[16] The exogenous administration of suppressive doses of glucocorticoid may cause a reduction of sebum secretion in women[17]

Sebum production was measured by a gravimetric technique[18] in twenty-two postmenopausal women with advanced breast cancer, aged 50 yr or older, who had never received exogenous hormone therapy All these women had undergone radical mastectomy some years before sebum testing Twenty women had undergone spontaneous menopause, although three patients had surgical oophorectomy 1–3 yr after established menopause, and two women were still menstruating at the time of surgical oophorectomy

As controls, thirty-one healthy premenopausal women in the fifth decade (ages 40 to 49 yr), thirty-five postmenopausal healthy females (ages 50 to 86 yr), and twenty-six postmenopausal women with advancing cancer in other sites were studied The latter group included seven reproductive (three ovarian, two endometrial, one cervical, one pelvic), two urinary, six gastro-intestinal, four head and neck, four lung, two unknown primary, and one lymphoma Two of the patients in this latter group had been treated with bilateral oophorectomy for gynaecological cancer, but both were long past spontaneous menopause at the time of surgery No hormonal therapy had been administered in any of these patients One woman had received abdominal irradiation 2 yr before sebum testing

Table 1. MEAN SEBUM CONCENTRATIONS IN WOMEN

Group	Sebum production (mg/10 cm²/3 h ± 1 standard error)	P values
(*a*) Premenopausal, normal	1 87 ± 0 20	
(*b*) Postmenopausal, normal	1 02 ± 0 10	
(*c*) Cancer, non-breast	0 97 ± 0 15	
(*d*) Breast cancer	2 11 ± 0 28	
(*a*) versus (*b*) and/or (*c*)		< 0 01
(*d*) versus (*b*) and/or (*c*)		< 0 01
(*a*) versus (*d*)		Not significant
(*b*) versus (*c*)		Not significant

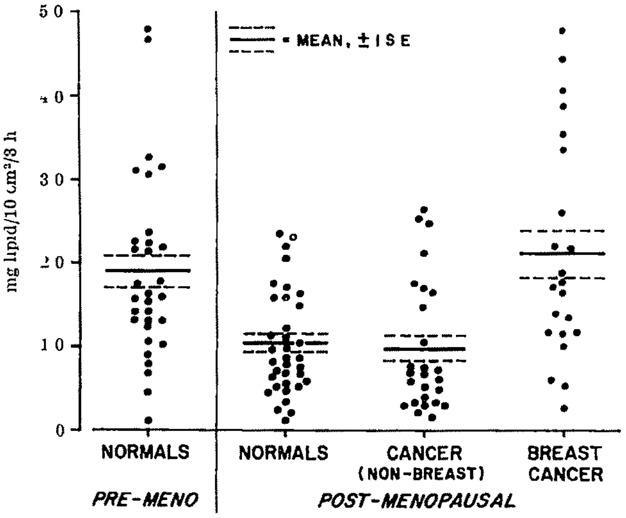

Fig 1 Sebum production in individual women studied

The mean ages of the three postmenopausal groups were postmenopausal healthy females, 67 0 yr, breast cancer patients, 62 0 yr, and cancer, non-breast patients, 65 0 yr

The sebum data (Fig 1 and Table 1) are expressed as mg of surface lipid/3 h period/10 cm² area of forehead skin Each subject was tested two or three times, 1–2 days apart, and the results averaged The mean level (mg/10 cm²/3 h) and one standard error of the mean in the groups is shown in Table 1 Statistical comparison of the postmenopausal healthy group versus the cancer, non-breast group (also postmenopausal), reveals no significant differences The value for the postmenopausal breast cancer group is significantly higher than the other two postmenopausal groups ($P < 0 01$) and is statistically similar to the premenopausal control group

Only three breast cancer patients had sebum values below the mean of the healthy postmenopausal control group Two of these three women had a prior oophorectomy (age 52 and 53 yr) Fifteen of the twenty-two breast cancer patients had values greater than two standard errors above the mean of the postmenopausal controls

It would seem that the sebaceous gland is stimulated by endogenous androgen, with testosterone, Δ^4-androstenedione and dehydroepiandrosterone as the likely agents in this regard These androgens have been shown to stimulate sebaceous gland activity when administered exogenously[16] The likely source of this stimulating material is the ovary or the adrenal gland or both

Seven women, from both postmenopausal cancer groups, had undergone surgical oophorectomy months to years before testing Resulting sebum values were 0 14, 0 51, 0 59, 1 16, 1 64, 2 18 and 3 35 mg That some of these women showed high levels of sebum production might indicate that the stimulating material is not uniquely ovarian in origin The mammalian adrenal is known to produce Δ^4-androstenedione and dehydroepiandrosterone, and is probably capable of synthesizing testosterone[19,20] A specific end organ sensitivity, however, cannot be excluded

Urinary androgen metabolites were not measured in these women, but reports in the literature indicate that excessive amounts of aetiocholanolone and androsterone have not been found in patients with breast cancer[21] The highly specific sebaceous gland target action of testosterone or Δ^4-androstenedione, however, may require only a small quantity of this material, which may not be reflected in either the urinary 17-ketosteroid level or the specific urinary 11-desoxy-17-oxysteroids Decreased biological activity of oestrogen by itself would not be expected to uncover a weak androgen effect on the sebaceous glands, inasmuch as studies have shown that there is no direct target-site antagonism between androgens and oestrogens[12]

The data suggest the possibility that postmenopausal women with advancing breast cancer are, in general, in an androgen-stimulated internal environment, and as a group are quite different in this regard from women with other advancing cancers and from healthy postmenopausal women, although virilizing effects were not observed in these patients (hirsutism, voice changes, acne lesions) Whether this androgen activity is secondary to advancing breast cancer or can be found with early non-metastatic cancer is now being investigated, as is the study of plasma androgen concentrations in relation to sebum production

PHYSIOLOGY

Effect of Oxygen Concentration on the Development of Two-cell Mouse Embryos

UNTIL recently, studies on early mammalian embryos were relatively infrequent because of difficulties in obtaining material and in maintaining the viability of the embryos New methods for routine collection and culture[1] have partially overcome these obstacles and several specific biochemical requirements for growing mouse embryos *in vitro* have been determined[2–6]. Using these methods, we have determined the oxygen concentration required by mouse embryos developing *in vitro*

Two-cell mouse embryos were cultured for three days *in vitro* in Brinster's medium for ovum culture[4], with the following concentrations of oxygen in the gas phase 19 9 per cent, 5 0 per cent, 2 5 per cent, 1 7 per cent, 1 5 per cent, 1 0 per cent, 0 5 per cent and 0 per cent In each experiment, one control group of embryos was gassed with 95 0 per cent air plus 5 0 per cent carbon dioxide, and balance nitrogen All experiments were maintained at atmospheric pressure To assure equilibration of the culture medium with a known oxygen tension (pO_2), a continuous flow of gas was used throughout the experiment The various proportions of gases were fixed by a system of pressure reduction valves and flowmeters, using air from a central compressor, carbon dioxide from a cylinder and a mixture of 95 0 per cent nitrogen plus 5 0 per cent carbon dioxide from a cylinder[7] Flow rates were set according to calibration charts provided by the Matheson Company In one experiment, the composition of the mixture, as prepared with the flowmeters, was checked by the method of Scholander, which is accurate to ±0 015 volume per cent[8] The calculated oxygen concentration was 0 97 per cent, and the analysis indicated the actual concentration was 1 15 per cent Because this mixture was one of the lower values of oxygen concentration used in the culture experiments and the required flow rates were in the least accurate range of the flowmeters, other higher concentration oxygen mixtures were presumed to be at least as accurate as this one

For each experiment, two-cell embryos from several mice were pooled and then distributed in groups of fifteen in several drops of culture medium Three days later, the number of morphologically normal blastocysts in each drop was recorded The fractional response was converted to an angular value[9] for the purpose of statistical analysis (see ref 10) Table 1 shows the mean angular responses and standard errors, as well as the mean percentage responses, for data which were pooled from several experiments at each oxygen concentration from 1 7 per cent to 0 per cent To analyse for the significance of differences in response, an analysis of variance was done for data from each concentration from 1 7 per cent to 0 5 per cent oxygen

Two-cell embryos develop into normal blastocysts in concentrations of 1 0 per cent oxygen and greater There was no significant treatment effect at 1 7 per cent, 1 5 per cent or 1 0 per cent oxygen At 0 5 per cent oxygen there was a significant decrease in the number of blastocysts developing from two-cell embryos ($P<0\ 001$) In an anaerobic atmosphere, 0 per cent oxygen, there was no development This indicates that equilibration of the gas with the culture medium occurred in a few hours, because not more than one cleavage occurred after the embryos were placed in the anaerobic incubator

Variation in developmental response of two-cell embryos to cultivation *in vitro* is caused by a number of factors, one of the most important being small variations in the age of the embryos at the beginning of culture Such variation accounts for the difference in response of the

Table 1

Oxygen concentration (volume per cent)	Mean angular response of normal development	Percentage response
1 7	42 93 ± 3 22	46
19 9	47 45 ± 2 68	54
1 5	45 03 ± 1 95	50
19 9	50 64 ± 2 29	60
1 0	31 32 ± 2 18	27
19 9	28 96 ± 3 32	24
0 5	17 98 ± 2 04*	10
19 9	31 88 ± 2 95	28
0 0	7 4 ± 0*	0
19 9	46 67 ± 2 40	53

The first four figures are mean responses from twelve drops of culture medium, fifteen embryos per drop The remaining are means of eighteen drops All means are ± standard error

* $P<0\ 001$

controls among the different experiments This does not affect the validity of the results, because equal numbers of control embryos and experimental embryos were taken from a common pool in each experiment

The fact that embryos develop a pO_2 of approximately 7 mm of mercury in 1 0 per cent oxygen, is not inconsistent with an aerobic metabolism Chance, Schoener and Schindler[11] have demonstrated by *in vivo* measurements on the rat brain that the pO_2 of extracellular blood is much less than 4 mm of mercury, when the electroencephalogram response and breathing stop At this pO_2, the nicotinamide adenine dinucleotide in the rat brain is reduced 80–90 per cent. This seems to be the level of reduction of pyridine nucleotide above which cellular function ceases The intracellular pO_2 at this degree of nucleotide reduction as measured in yeast is less than 0 1 mm of mercury

These results indicate that the mouse embryo is capable of normal development *in vitro* at very low oxygen tensions Whether this capacity is ever utilized *in vivo* is not known, because oxygen tensions of 40–75 mm of mercury have been found in the Fallopian tube of the rabbit[12]

Stimulus-induced Release of Substances from Olfactory Bulb using the Push–Pull Cannula

SEVERAL methods have been used to study neurohumoral release within the mammalian brain These include the use of collecting cups affixed to the cortical surface[1–5], ventricular cannulae for the perfusion of cerebrospinal fluid pathways[6–8] and the push–pull cannula[9] With the last device. perfusion fluid is passed through the inner tube of a concentric dual-barrelled cannula and is recovered by siphoning through the outer barrel Because it makes possible perfusion of small regions of cerebral tissue, even in the depths of brain, the push–pull cannula has been widely used to investigate the spontaneous and stimulus-induced release of acetylcholine[2,10–17]

Certain nerve terminals in the olfactory bulb contain substantial quantities of norepinephrine and serotonin[18,19] The microelectrophoretic administration of either of these monoamines to some bulb neurones alters their firing patterns[20] These findings, together with the well documented effects of drugs which deplete or antagonize monoamines in the olfactory bulb[21,22], suggest that norepinephrine or serotonin may serve as neuromediators in this structure and prompted the present study Using the push–pull cannula we found that olfactory stimulation caused a marked increase in the efflux of radioactively labelled norepinephrine and serotonin from the rat olfactory bulb Stimulation also increased the efflux of labelled inulin and other inert substances which are unlikely to have transmitter function Evidence for the release of potential neurotransmitters using the push–pull cannula in brain, which does not include controls for non-specific release, should therefore be interpreted with caution.

Adult Osborn–Mendel rats were lightly anaesthetized with 15 per cent urethane (approximately 1 ml /100 g body weight, injected intraperitoneally) Then either ^{3}H-7-D,L-norepinephrine (10 μc , specific activity 8 8 c / mmole) or ^{3}H-serotonin (25 μc , specific activity 2 1 c / mmole) was injected into the cisterna magna When norepinephrine or serotonin is administered intracisternally, its regional and subcellular distribution seems to follow that of the endogenous amine[23–26] In these experiments, assay of the olfactory bulbs of four rats killed 60–90 min after intracisternal injection of ^{3}H-norepinephrine confirmed the substantial accumulation (4–13 mμc /mg) of the exogenous amine and of its metabolites

Under stereotactic control, the push–pull cannula (fashioned from a 15 gauge needle and Clay–Adams *PE*-20 polyethylene tubing) was inserted 1 mm beneath the surface of the bulb, and perfusion with Elliot's *B* irrigating solution (Baxter Laboratories) at 37° C was begun at a rate of 0 2 ml /min The perfusate was collected during consecutive 1 min intervals and assayed for total radioactivity by liquid scintillation spectrometry Tritium levels followed a multiphasic exponential decay curve which tended to plateau after approximately 30 min of perfusion Throughout the experiment, a gentle stream of air was delivered at a constant rate into both nostrils by means of plastic catheters A switching device allowed the air current to be bubbled through either pure water or a dilute aqueous solution of such odorous substances as pyridine, isoamyl alcohol, *n*-heptane or almond extract

When the tritiated amine levels were steady (40–200 min after the intracisternal injection of either ^{3}H-norepinephrine or ^{3}H-serotonin), the animal was exposed to an odour for 1 min This stimulus consistently resulted in a three to ten-fold rise in the tritium efflux above baseline levels (Fig 1*A*) Such odour-induced alterations in tritium efflux could be repeated up to four or five times after a single intracisternal injection The increased efflux was detectable immediately on stimulation, was usually maximal during the second 1 min interval following cessation of stimulation and persisted for 3–5 min thereafter An exposure of at least 15 sec to an odorant was necessary to produce detectable release

Several tests of the specificity of these findings were then carried out (1) There was no change in the efflux of labelled monoamine during exposure to loud noises or on electrical stimulation (1–5 V, 3 msec, 20 Hz) of the contralateral forepaw for 1 min It thus seemed unlikely that the odour-induced alterations in tritium efflux resulted from a general arousal reaction (2) The changes induced by odour were not reduced in animals previously subjected to bilateral superior cervical ganglionectomy, thus indicating that release was not dependent on the sympathetic innervation of the olfactory bulb (3) In order to examine the possible influence of local alterations in the integrity of the blood–brain barrier or in the cerebral blood flow, the standard intracisternal dose of ^{3}H-norepinephrine (10 μc) was given intravenously In these circumstances, no spontaneous or odour-induced efflux of tritium from the olfactory bulb was detectable

As a further test of the specificity of the stimulus-induced release of potential neurotransmitters found in these experiments, several metabolically inert, ^{14}C-labelled substances such as inulin (1 μc , 3 8 mc /g), urea (1 μc , 5 1 mc /mmole), or α-aminoisobutyric acid (1 μc , 0 32 mc /mmole) were injected with the ^{3}H-amines On odorous stimulation, a substantial rise in the efflux of the ^{14}C-labelled compound invariably accompanied the augmented ^{3}H-amine efflux (Fig 1*B* and *C*) Tests with increasingly mild odorant exposures revealed no dif-

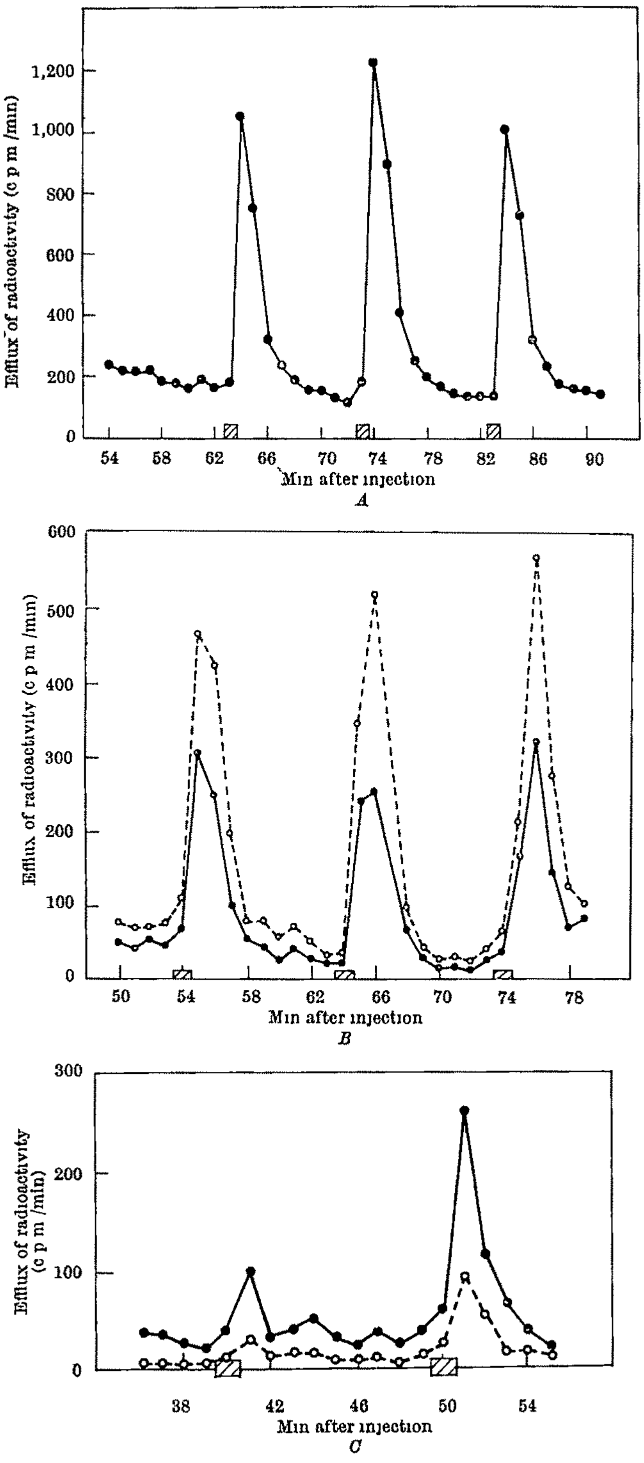

Fig 1 Odour-induced changes in the efflux of radioactivity from the rat olfactory bulb following intracisternal injection of (*A*) 10 μc ^{3}H-7-norepinephrine, (*B*) ^{3}H-norepinephrine (●) plus 1 μc ^{14}C-urea (○), or (*C*) ^{3}H-norepinephrine (●) plus 1 μc of ^{14}C-inulin (○) Nostrils were exposed to isoamyl alcohol vapour for 1 min at the times indicated In *A* and *B*, rats were anaesthetized with urethane, in *C*, immobilized with *d*-tubocurarine and artificially ventilated

ference in threshold between norepinephrine and inulin A wide anterior craniotomy was performed in several animals in an attempt to reduce possible stimulus-related changes in intracranial pressure This procedure failed to modify the odour-induced response of either of the compounds The odorant-increased efflux of both inulin and the amines was not disassociated in artificially ventilated, unanaesthetized rats immobilized with *d*-tubocurarine (Fig 1*C*). These animals were prepared under general anaesthesia and subsequently received local anaesthesia to all pressure points and wound margins It did not seem that the concurrent efflux of these substances could be attributed either to the anaesthesia or to the respiratory changes which occasionally accompanied odorant stimulation

Inulin injected into cerebrospinal fluid remains largely, if not exclusively, in the "extracellular" space[27], so the odour-induced alterations in its efflux found here suggest that local changes within this compartment may attend neural stimulation During perfusion with the push–pull cannula, a steep concentration gradient may be created in the artificial extracellular space surrounding the cannula tip Relatively small variations in hydrostatic pressure or in the transport or diffusion rates of extracellular components might produce substantial changes in the concentration of these substances in the push–pull cannula perfusate Although there is convincing evidence that labelled norepinephrine injected into the cerebrospinal fluid is rapidly taken up into intraneuronal stores[23], it is impossible to decide whether the stimulation-induced alterations in norepinephrine efflux reflect physiological release from such intracellular stores or merely extracellular shifts of residual exogenous amine

While these considerations may be less important when the push–pull cannula is used to study the release of endogenous substances, the inevitability of perfusing traumatized tissue in which the normal intra–extracellular barriers may be compromised seriously complicates the interpretation of results Improved controls are necessary before data derived from the push–pull cannula can be confidently cited as evidence of release of potential cerebral neurotransmitters

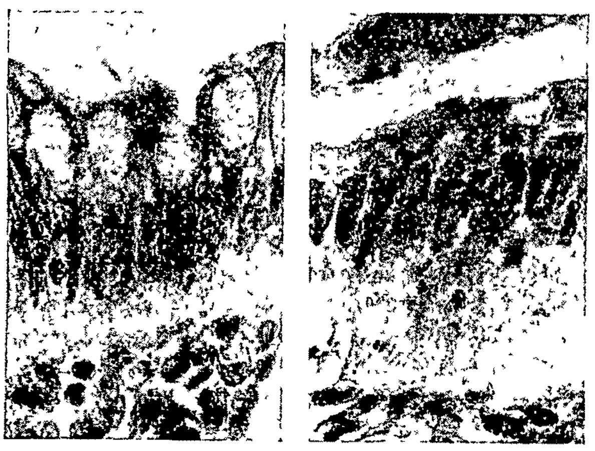
Effect of Secretin on Human Rectal Mucosa *in vivo*

It is now more than 60 years since secretin was discovered and since its significance with respect to pancreatic and biliary secretion was recognized[1]. Later investigations have led to the conclusion that pancreatic juice[2] and bile[3] can both be considered to be a mixture of two fluid components which are probably secreted by different cells and under independent physiological control, that is, they are made up of a fluid which is rich in electrolytes and a fraction containing a high concentration of the macromolecular secretory products of the exocrine cells. The principal effect of secretin seems to be to stimulate formation of the "electrolyte fraction", but its precise mode of action is still unknown.

Despite widespread investigations, there is no conclusive evidence that secretin has any physiological effects on tissues other than the exocrine pancreas and the liver. In particular, detailed studies have failed to show any effect on Brunner's glands[4] or on the transfer of fluid and electrolytes across the rat ileum[5] and frog skin[6]. Recent observations which were made in this laboratory, however, suggest that secretin may have some action on human rectal mucosa—an epithelium across which considerable movement of water and electrolytes is known to occur.

During tests of pancreatic function on children with cystic fibrosis (CF) and on healthy controls[7] rectal suction biopsies were taken, both at the start of the test and 15 min after injection of secretin (2 IU/kg body weight in 5 ml of isotonic saline). A multipurpose biopsy tube was used and the specimens, which were obtained 5–6 cm from the anal orifice, were fixed in Bouin's solution. Paraffin sections (6µ) of the fixed tissue were stained with haematoxylin and eosin and with stains specific for mucosubstances (for example, colloidal iron-PAS and toluidine blue).

After secretin had been injected the surface epithelium of the rectal mucosa showed distinct changes which were not seen in the specimens at zero time: the nuclei seemed to be displaced towards the luminal surface while the area at the base of the cells, between the nuclei and the subepithelial connective tissue, took on a "fuzzy" appearance (Fig. 1). These changes were seen in every post-secretin specimen, but the entire surface layer was not always equally affected. Furthermore, there were no well defined effects on the goblet cell mucus which could be shown histochemically. Injection of 5 ml of isotonic saline alone produced no visible changes in the appearance of the mucosa. Similar results were observed in both CF and control tissue, but the CF response to secretin seemed to be less marked; it must be stressed, however, that this is a qualitative observation which was made on a small number of cases only (that is, three CF and three controls).



A *B*

Fig. 1. *A*, Surface epithelium of human rectal mucosa before injection of secretin (× 1,120). *B*, Rectal mucosa from the same subject 15 min after injection of secretin (× 1,120).

The precise interpretation of these observations is not clear, but we suggest that the appearance indicates changes at the base of the epithelial cells, possibly in the extracellular region—a site which may well be important in controlling the rate of movement of fluid from the connective tissue proper into the cells. Polyelectrolyte mucoid material has been shown external to the plasma membrane of many cell types[8], and could envelope virtually all cells (the "extraneous mucoid coat")[9]. Interaction of a polar polypeptide such as secretin with this extracellular layer could well cause structural alterations, resulting in the modification of its "porosity" towards fluid and electrolytes. Thus the changes which we have observed could indicate an effect on fluid distribution at the base of the epithelial cells which are actively involved in fluid transfer.

The effect of secretin both on rectal mucosa and on the exocrine pancreas is now being studied in greater detail in rats and kittens, with special emphasis on the mechanism by which fluid movement in these tissues is controlled.

Calcium Spikes of Nerve Cell Membrane: Role of Calcium in the Production of Action Potentials

This communication reports the observation that the membrane of bullfrog sympathetic ganglion cells is capable of producing action potentials (calcium spikes) in an isotonic solution of calcium chloride in response to cathodal currents which are applied through an intracellular recording microelectrode[1].

In record 1 of Fig. 1, the action potential (sodium spike) which was produced in Ringer's solution is shown. The calcium spike which was obtained after a ganglion was perfused with an isotonic solution of calcium chloride (83 mmolar) containing 2 mmolar potassium bicarbonate for more than 3 h is shown in record 2. The resting membrane potential and the effective membrane resistance in this solution (mean values for seven cells being approximately 100 mV and 200 MΩ, respectively) were much larger than those in Ringer solution (mean values for ten cells being approximately 65 mV and 40 MΩ, respectively). The threshold for initiation of calcium spikes was considerably higher than that for sodium spikes, the threshold membrane potentials ranged from −5 to −10 mV (among seven cells) in the isotonic

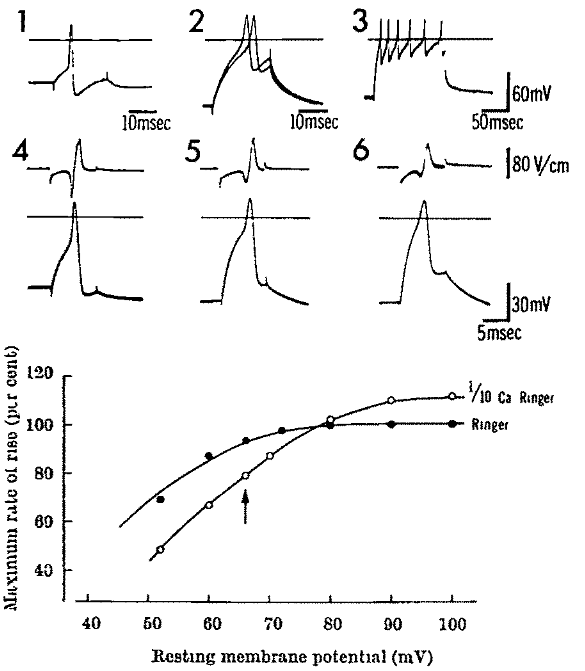

Fig 1 Record 1 shows the action potential of a ganglion cell in Ringer solution, and records 2 and 3 show the action potentials of two other cells of the same preparation in an isotonic solution of calcium chloride Records 4, 5 and 6 were obtained in succession from a cell of a different preparation during perfusion with a solution containing 57 mmolar sodium chloride, 1 8 mmolar calcium chloride, 2 ml mmolar potassium bicarbonate and 114 mmolar sucrose, 5 min after the perfusate was changed to a solution containing 57 mmolar sodium chloride, 41 5 mmolar calcium chloride and 2 mmolar potassium bicarbonate, and 8 min after addition of tetrodotoxin (5×10^{-6} g/c c), respectively An electrically differentiated record of each potential wave lies immediately above them The graph shows the maximum rate of rise of the spike action potentials of a cell induced at varying membrane potential levels during perfusion with Ringer solution and with a low calcium (0 18 mmolar) Ringer solution was plotted against the membrane potential level The membrane potential level was varied by applying anodal or cathodal currents through the recording microelectrode Arrow indicates membrane potential level in the absence of extrinsic currents The largest rate of rise in Ringer solution is taken to be 100 per cent

solution of calcium chloride and from −40 to −45 mV (among ten cells) in Ringer solution The overshoot of the calcium spike was larger than that of the sodium spike, the peak potentials of the sodium and calcium spikes ranged from 25 to 30 mV and 40 to 50 mV respectively The mean values of the maximum rates of rise of the calcium spikes (seven cells) were about 25 per cent of those of the sodium spikes (ten cells) Because the IS-component of the calcium spikes could not be isolated[1], it was assumed that the calcium spikes had originated from the soma membrane Repetitive responses (calcium spikes) were readily produced if a strong cathodal current was applied (record 3, Fig 1)

The value of the peak potential of the calcium spike was almost linearly proportional to the calcium concentration in the external solution (the calcium concentration was altered by replacing calcium chloride with equimolar amounts of sucrose), the increment for a ten-fold increase in the calcium concentration being about 30 mV This suggests that the inward movement of calcium across the membrane is responsible for the production of the calcium spike No action potentials were produced with calcium at a concentration less than 5 mmolar The calcium spike was more resistant to tetrodotoxin than was the sodium spike The sodium spike disappeared within 5 min in the presence of 5×10^{-7} g/ml of tetrodotoxin, whereas the calcium spike was depressed but not abolished in the presence of 5×10^{-6} g/ml of tetrodotoxin Procaine (5×10^{-3} g/ml), which blocked the sodium spike within a few minutes, markedly prolonged the falling phase and slightly depressed the rising phase of the calcium spike The characteristics of the calcium spikes resembled those of the anthropod muscle[2] and of the molluscous giant nerve cells[3-5]

In Ringer solution containing 1 8 mmolar calcium, the calcium current may be very small compared with the sodium current during the action potential The calcium current, however, seems to make a considerable contribution to the inward current during the action potential produced in a solution of sodium containing a relatively large amount of calcium Furthermore, the calcium in a solution of sodium is able to depress the sodium current[6] These actions of calcium can be seen in records 4, 5 and 6 of Fig 1 Record 4 was obtained in a solution containing 57 mmolar sodium and 1 8 mmolar calcium (isotonicity was maintained with 114 mmolar sucrose) When the calcium concentration was increased to 41·5 mmolar, the level of the threshold membrane potential was markedly raised and the maximum rate of rise of the action potential was decreased conspicuously, while the peak level of the action potential was increased, as seen in record 5 When tetrodotoxin (5×10^{-6} g/ml) was added to the perfusate, the threshold membrane potential level was raised further and the maximum rate of rise of the action potential was rapidly decreased to a certain extent within a few minutes without appreciably changing the peak level, and then remained there, this would be the calcium spike (record 6)

Another effect of calcium which was observed with the present preparation was that it removed inactivation of the sodium carrying system[6] This is graphically illustrated in Fig 1, in which the maximum rate of rise of the sodium spike produced at a relatively low resting potential level is decreased in Ringer solution containing 0 18 mmolar calcium

In conclusion, calcium is capable of (1) acting as a charge carrier, (2) removing sodium inactivation, and (3) depressing the sodium current during the production of the action potential of sympathetic ganglion cells

Effects of Vasopressin, Theophylline and Cyclic Adenosine Monophosphate on Short-circuit Current across Isolated Rabbit Ileal Mucosa

VASOPRESSIN causes rapid, equal increases in short-circuit current (Isc) and rate of transport of sodium when added to the serosal surface of frog skin or toad bladder[1,2]. Several investigators have presented convincing evidence that this alteration in the active transport of sodium is primarily, if not entirely, a consequence of increased passive permeability of the mucosal surface to sodium, as well as to other small hydrophilic solutes[3-5] Adenosine-3′ 5′-monophosphate (cyclic AMP) and theophylline have been shown to mimic the effects of vasopressin on Isc and osmotic water flow across toad bladder[6] It has been suggested that cyclic AMP is the more direct mediator of the permeability change and that vasopressin and theophylline exert their effects by increasing the concentration of cyclic AMP in the epithelial cells[7].

Theophylline and cyclic AMP have been observed to increase acid secretion but not Isc across frog gastric mucosa[8] Vasopressin has been observed to cause a marked but transient increase in Isc across stripped guinea-pig caecum[9] and to cause a small but more prolonged increase in Isc and osmotic water flow across toad colon[10] It would therefore seem that these compounds could alter ion transport in several epithelial membranes, including mammalian intestinal mucosa, but that the ion transport systems which are affected might not be the same in every instance

We have observed an increase in Isc when either vasopressin, theophylline or cyclic AMP was added to the serosal surface rabbit ileal mucosa *in vitro* Observations on the Isc alterations caused by these compounds in sodium chloride, choline chloride and sodium sulphate containing Ringer solutions are presented in this communication Changes in Isc were determined rather than changes in electrical potential alone, because the former directly measures net ion transport across the tissue while the latter depends on passive ion permeability as well, which can be greatly altered by changes in ionic composition of the bathing medium.

Segments of distal ileum from New Zealand white male rabbits were stripped of their outer mesothelium and two principal muscle layers, and were clamped as flat sheets between two identical half chambers Mucosal and serosal surfaces of the tissues were perfused at 37° C from separate reservoirs containing oxygenated solutions which were identical except for the addition of D-glucose (15 mmolar) to the serosal side and D-mannitol (15 mmolar) to the mucosal side Unless otherwise stated, the perfusates had the following ionic composition in mmoles/l sodium, 141, potassium, 10, calcium, 1 25, magnesium, 1 1; chloride, 127; bicarbonate 25, dihydrogen phosphate, 0 3; hydrogen phosphate, 1 6 In some experiments choline was substituted for sodium and sulphate was substituted for chloride (sodium, 185, sulphate, 83) or for both chloride and bicarbonate (sodium, 193, sulphate, 100) Perfusates were continuously gassed with 95 per cent oxygen, 5 per cent carbon dioxide if they contained bicarbonate and with 100 per cent oxygen if they did not Apparatus and methods which were used for the determination of Isc were essentially those previously described[11] In many experiments a continuous recording of Isc was obtained by using an automatic voltage clamp

Compounds were not tested until the Isc was stable and at least 20 min had elapsed after the beginning of perfusion At the end of each experiment the viability of the tissue was established by eliciting a substantial increment in Isc on the addition of D-glucose (15 mmolar) to the mucosal perfusate (choline was replaced by sodium before adding glucose)

Vasopressin ('Pitressin', Parke Davis) caused a large but transient (2–5 min) increase in Isc within 30 sec of addition to the serosal perfusate at concentrations as low as 5 mU/ml A maximal response seemed to be attained at a concentration of 25–75 mU/ml The short duration of the effect was manifested at concentrations as high as 2 U/ml Vasopressin (400 mU/ml) was ineffective when added to the mucosal perfusate alone The effects of synthetic arginine and lysine vasopressin (Sandoz Pharmaceuticals) on Isc were indistinguishable from that of 'Pitressin'

The increment in Isc induced by vasopressin disappeared despite the persistence of active hormone in the perfusate This was shown when the original perfusate was added to another piece of mucosa eliciting another large increase in Isc Furthermore, the addition of a second increment of vasopressin equal to the first failed to produce another response whether it was added immediately after the initial effect had disappeared or 1 h later A substantial second response was elicited, however, by first washing the serosal surface with vasopressin-free solution (three changes of solution) and then adding the amount of vasopressin which was originally used A response was produced in this way as early as 10 min after the first change of solution A moderate second response was also elicited when a modest initial concentration of vasopressin (7 to 20 mU/ml) was followed by a twenty-fold increment in concentration.

Table 1 INCREMENT IN ISC (μAMP/CM^2)

Compound	Ringer solution Sodium, chloride, bicarbonate	Choline, chloride bicarbonate	Sodium, sulphate, bicarbonate	Sodium, sulphate
Vasopressin (50–400 mμ/ml)	110 ± 9 (11)	0 (5)	11 ± 3 (5)	0 (8)
Theophylline (5–10 mmolar)	123 ± 14 (10)	22 ± 2 (9)	34 ± 10 (4)	0 (8)
Cyclic AMP (3–7 5 mmolar)	97 ± 11 (9)	30 ± 6 (4)	21 ± 1 (3)	0 (8)
D-Glucose (10–15 mmolar)	87 ± 5 (5)	0 (2)	44 ± 5 (5)	46 ± 11 (5)

Arithmetic mean values ± 1 S E M are given No of experiments in parentheses

While the present observations do not permit formulation of a precise mechanism for the transient character of the Isc response to vasopressin, they are consistent with the following two general mechanisms, one of which might be relevant (1) Vasopressin might be rapidly inactivated by intracellular enzymes and both active and inactive forms of vasopressin might compete for specific hormone receptor sites A second vasopressin response might only occur therefore if a critical ratio of active to inactive intracellular hormone concentrations were exceeded (2) The metabolic events set into motion by vasopressin could rapidly deplete the mucosal cell of a compound which is essential for the Isc response and the continued presence of the hormone or one of its metabolites could inhibit resynthesis of this compound

Cyclic AMP (1 to 7 5 mmolar) and theophylline (1 to 10 mmolar) caused rapid and sustained increases in Isc when added to the serosal perfusate (Table 1). This effect was almost completely inhibited by 10^{-4} molar ouabain which was added 15 min earlier The earlier addition of vasopressin did not diminish the subsequent response to theophylline or cyclic AMP. Maximal amounts of the latter compounds, however, completely prevented a subsequent vasopressin response

To determine which ions are involved in these increases in Isc, the effects of vasopressin, cyclic AMP, theophylline and glucose on Isc across mucosae perfused in choline, sulphate–bicarbonate and pure sulphate Ringer solutions were compared (Table 1) The effects of mucosal glucose are included here in order to show that sodium transport can be stimulated in the absence of any chloride or bicarbonate in the perfusate Although responses were considerably smaller in choline and solutions containing sulphate, definite sustained increases in Isc were caused by cyclic AMP and theophylline in the absence of sodium and in the absence of chloride, but not in the absence of both chloride and bicarbonate Further experiments with theophylline in bicarbonate-free sodium chloride Ringer solution showed that a substantial Isc response can also be obtained in the absence of bicarbonate provided that chloride is present

These results suggest that both chloride and bicarbonate are actively secreted by rabbit ileum in response to cyclic AMP and theophylline. Whether or not vasopressin also elicits an anion secretory response cannot be surmised as the hormone did not significantly alter Isc in solution of either choline or sulphate.

Teratogenic Effects of Hypoglycin-A

HYPOGLYCIN-A[1] has been shown to be a non-proteinogenic amino-acid of the structure L-α-amino-β-methylenecyclopropanepropionic acid[2] It is the toxic element of the fruit of *Blighia sapida* (called "ackee" in Jamaica) which is a common Jamaican dietary item Hypoglycin is considered to be responsible for the "vomiting sickness", an acute condition, frequently observed in Jamaica, which is characterized by persistent vomiting and a coma[3,4] In experimental animals, hypoglycin-A causes a delayed hypoglycaemia, vomiting[1,5] and fatty degeneration of the liver[6]

The teratogenicity of hypoglycin-A was tested on pregnant albino rats weighing between 170 and 180 g The first day of pregnancy was considered to be the morning when sperm was found in the vaginal smear Fifteen pregnant rats were then given daily intraperitoneal injections of an aqueous solution of hypoglycin-A (70 per cent of the pure substance, 30 mg/kg body weight), from the first to the fifth day of gestation The animals were kept in individual cages at room temperature (22°–25° C) and were fed a standard 'Purina' rat chow and were provided with unlimited water Foetuses which had been recovered from pregnancies terminated on the nineteenth and twentieth days of gestation were weighed and examined for the presence of external malformations, foetal resorption sites were counted and random foetuses from each litter were fixed in Bouin's solution Free-hand sections were made and examined for visceral malformations[7]. Thirteen pregnant animals, which were not treated, served as controls

Table 1 TERATOGENIC EFFECTS OF HYPOGLYCIN-A ON THE RAT EMBRYO

Pregnant rats	Total implantations	Resorptions	Malformed foetuses	Normal foetuses
Treated with hypoglycin-A	125	7	(110) 18 E 8 E 84 E+S	8
Control	105	1	(6)	98

E, Exencephalocoele, S, syndactyly

The results are shown in Table 1 The incidence of foetal malformations, resportion of foetuses and retarded foetal development (decrease in size and weight) in the groups of animals which were treated was significantly higher than in the control groups The abnormalities observed were exencephalocoele and syndactyly The numbers in the litters were not affected

I thank Professor C von Holt, former head of the Department of Biochemistry, University of the West Indies, Jamaica, for the supply of hypoglycin-A

Effect of Dietary Carbohydrate on Hepatic Lipogenesis in the Rat

IT has been suggested that dietary sucrose is implicated in the aetiology of ischaemic heart disease[1] If this were so, dietary sucrose would produce different metabolic effects from other dietary carbohydrates. In man and experimental animals, substitution of sucrose for starch in the diet can result in diminished growth, increased concentrations of serum cholesterol and alterations in liver lipids[2–4] Elevated concentrations of plasma triglyceride result in man from eating sucrose[5–6] or fructose[7] as compared with glucose, while the substitution of fructose or sucrose for glucose or starch in the diets of rats causes an increased liver lipid content[8] These results suggest that the effects of sucrose are caused by the fructose content of the sugar

The purpose of the experiments reported here was to study the influence of dietary sucrose, fructose, glucose and rich starch on hepatic lipogenesis and the activities of some enzymes thought to be associated with lipogenesis

Male Wistar rats were given the experimental diets *ad libitum* for 6 days and were 45–49 days old when killed The standard diet used contained 62 8 per cent soluble carbohydrate, 23 per cent protein 4 4 per cent fat, 3 8 per cent fibre and 6 0 per cent ash One group of animals was maintained on the standard diet, but their drinking water was replaced by 20 per cent fructose The rest of the diets consisted of 68 per cent of the stated carbohydrate, 24 per cent casein, 3 9 per cent mineral salts mixture[10], 0 48 per cent corn oil. 0 48 per cent cod liver oil, 2 9 per cent gelatine and 0 58 per cent yeast extract Enzyme activities and acetate incorporation into lipid were estimated by methods described by Taylor, Bailey and Bartley[9]

Table 1 shows that provision of dietary carbohydrate in the form of fructose rather than glucose results in higher activities of hepatic pyruvate kinase, malic enzyme and ATP citrate lyase This confirms the results of Freedland, Cunliffe and Zinkl[11] and Kornacker and Lowenstein[12] In animals given the diet containing sucrose enzyme activities were intermediate between those of the fructose and glucose fed animals When the dietary carbohydrate was given as diet 86, enzyme activities were similar to those of the animals fed on glucose In diet 86, the carbohydrate is predominantly barley and wheat starch It is interesting that much greater activities of enzyme are found if rice starch is used as the source of carbohydrate The difference in pyruvate kinase activities between rats fed sucrose and diet 86 supports the suggestion of Bartley *et al* [10] and Yudkin and Krauss[13] that the high rat liver pyruvate kinase activities reported by Krebs and Eggleston[14] when they fed animals high

Table 1 CHANGES IN LIVER WEIGHT AND ACTIVITY OF SOME RAT LIVER ENZYMES AND OF [1-^{14}C] ACETATE INCORPORATION INTO RAT LIVER LIPIDS WITH CHANGE IN DIET

Diet	Pyruvate kinase activity (μmoles substrate utilized/min/g wet weight of liver at 25° C)	Malic enzyme activity (μmoles substrate utilized/min/g wet weight of liver at 25° C)	ATP–citrate lyase activity (μmoles substrate utilized/min/g wet weight of liver at 25° C)	Acetate incorporated into lipid (μmoles/90 min/g of liver slice)	Liver weight (percentage body weight)
Diet 86	31.0 ± 1.1 (5)	6.5 ± 0.69 (6)	1.11 ± 0.12 (6)	1.06 ± 0.29 (11)	4.45 ± 0.17 (10)
Fructose	85.0 ± 10.9 (5)	13.9 ± 1.70 (6)	3.51 ± 0.83 (6)	0.58 ± 0.18 (12)	5.25 ± 0.17 (10)
Glucose	38.0 ± 4.4 (5)	7.5 ± 0.80 (6)	1.69 ± 0.51 (6)	1.00 ± 0.23 (12)	4.85 ± 0.20 (10)
Sucrose	66.5 ± 12.2 (5)	9.6 ± 0.86 (6)	2.99 ± 0.48 (6)	0.62 ± 0.19 (11)	4.70 ± 0.19 (10)
Rice starch	50.0 ± 3.3 (5)	9.2 ± 2.27 (6)	1.96 ± 0.35 (6)	0.40 ± 0.08 (12)	4.35 ± 0.21 (10)
Diet 86 + 20 per cent fructose	90.0 ± 5.9 (5)	NE	NE	NE	NE

The results are given as means ± *S.E.M.* with the number of observations in parentheses. NE, not estimated. The rats were given the experimental diets for 6 days.

carbohydrate diets were, at least in part, caused by the nature of the carbohydrate (sucrose). Table 1 also shows that hepatic pyruvate kinase activities can be raised if drinking water is replaced by 20 per cent fructose.

Although the activities of hepatic enzymes thought to be associated with lipogenesis are found to be higher in animals receiving dietary fructose or sucrose than in those fed diet 86 or glucose, acetate incorporation into lipid of liver slices was lower. A similar result was obtained for the animals fed on starch. Zakim *et al.*[15], also using liver slices, were unable to detect a difference in acetate incorporation between animals fed fructose, glucose and sucrose, but there was greater incorporation of acetate into lipid by homogenates of liver from rats which had been fed a sucrose rich diet than from those given a starch rich diet[16].

Although our results suggest that the activities of some liver enzymes depend on the nature of the dietary carbohydrate, it is possible that the effects were caused by ingestion of different quantities of the various carbohydrates. Table 2 shows the amount of carbohydrate eaten and the weight gained by the groups of rats. The increased enzyme activities produced by fructose and sucrose cannot be explained by greater intake of these two carbohydrates. If isocaloric diets had been given, the difference between the fructose and sucrose results and the others would probably have been greater. There seems to be a difference in enzyme activity produced by dietary rice starch compared with dietary wheat and barley starch (diet 86). Provision of fructose in the diet not only led to a low carbohydrate intake compared with the other diets but also resulted in the least weight gain (Table 2).

Table 2 AMOUNT OF CARBOHYDRATE EATEN BY, AND WEIGHT GAIN OF, RATS GIVEN VARIOUS DIETS

Diet	Carbohydrate eaten (g/day/rat)	Weight gain (g/day/rat)
Diet 86	11.1	2.9
Fructose	6.5	0.8
Glucose	9.3	2.0
Sucrose	8.0	2.0
Rice starch	11.7	1.9
Diet 86 + 20 per cent fructose	12.1 (7.1 from diet 86 and 5.0 from 20 per cent fructose)	1.9

The animals were given the experimental diets for 6 days. The results are the means for twenty-eight rats except for the diet 86 + 20 per cent fructose when only ten animals were used.

Changes in the activities of enzymes in response to changes (of quantity or kind) of dietary carbohydrate are presumably secondary to changes in the concentrations of specific metabolites which induce the enzymes. Three responses can be distinguished if the diets differ in quantity of carbohydrate[14], nature of the monosaccharide or the polymeric state of the carbohydrate. Two factors are important in considering how the diets affect amounts of inducer: first, the rate at which the sugar is presented to the liver, which is governed by the rate of digestion and absorption, and second, the manner in which different monosaccharides are metabolized by the liver.

In the absence of evidence that glucose and fructose are absorbed at grossly different rates, differences in their metabolism must explain nutritional dissimilarities. When fructose or sucrose are fed to rats a considerable amount of fructose is thought to reach the liver[17]. Fructose which is metabolized by the liver to dihydroxy acetone phosphate and glyceraldehyde and then through the glycolytic sequence to pyruvate, is utilized by liver slices much more rapidly than glucose[18]. By-passing the rate limiting phosphofructokinase step of glycolysis (which is the point of feedback control by ATP and citrate[19]) is likely to result in more rapid conversion of fructose to pyruvate than of glucose to pyruvate. In man, feeding fructose leads to higher concentrations of blood pyruvate than does feeding glucose[20,21]. The increase in pyruvate kinase produced by fructose diets is probably a result of accumulation of a metabolite intermediate between fructose and pyruvate, and because animals fed on starch have a higher content of hepatic pyruvate kinase than starved animals[14] it is probable that the inducer is on that part of the glycolytic pathway common to fructose and glucose metabolism. There is a species difference in control of pyruvate kinase by carbohydrate. Mouse liver pyruvate kinase activities show little alteration with change in diet (unpublished results).

An increase in pyruvate formation with fructose or sucrose diets would cause increased formation of acetyl-Co*A*. The excess acetyl-Co*A* may be utilized for fatty acid synthesis. The increase in the activities of malic and citrate cleavage enzymes, thought to be associated with lipogenesis, is in accord with this view, so it was surprising that the rise in these two enzymes was not accompanied by an increased incorporation of ^{14}C acetate into the lipid of liver slices. It is possible that the postulated increase in the acetate pool would cause dilution of the labelled acetate so that its incorporation would not give an adequate index of lipogenesis.

Tetrapod Characteristics of the Pituitary Gland of *Calamoichthys calabaricus*

Calamoichthys and the better known *Polypterus* comprise the most primitive group of living ray-finned fishes, and are regarded as palaeoniscid relics[1-4]. Some of the earliest reports on the morphology of the fish pituitary gland concern this group[5-7]. In re-evaluating the morphology of the pars distalis in primitive actinopterygian fishes, a portal vascular system between the inferior surface of the infundibulum and the sinusoids of the pituitary gland was discovered in *Calamoichthys*.

India ink injected through the heart of the anaesthetized animal revealed the portal system to good advantage (Fig. 1). Two small arteries ramify within the meninges and converge along the inferior surface of the infundibulum. They then directly enter the pars distalis and constitute the sole demonstrable vascular supply to the entire pituitary gland. The morphology of the primary capillary bed of the portal vessels is similar to that of tailed amphibians[8]. Electronmicroscopy of the median eminence reveals a morphology indistinguishable from that of various amphibians[9,10]. Axons containing elementary neurosecretory granules measuring 1000–1500 Å and synaptic vesicles measuring 500 Å abut against a loose pericapillary space which is 4000 Å wide (Fig. 2). Occasional fenestrae are seen in the capillary endothelium. There seems to be no specialization of the pars distalis into a terminal zone or tuberal region as in the lungfish *Protopterus*[11,12] or in tetrapods.

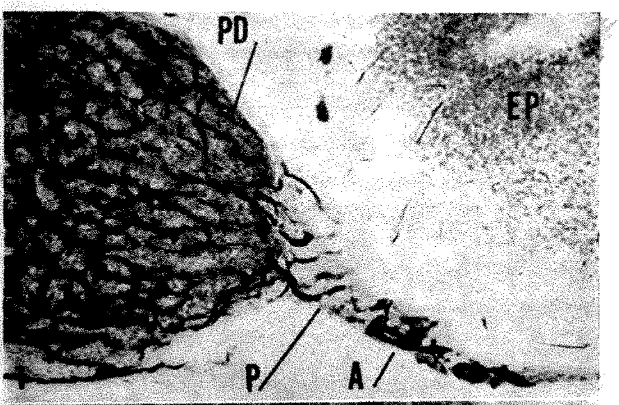

Fig. 1. Parasagittal 50μ thick nitrocellulose section of median eminence. India ink was injected. A, Artery of primary capillary bed; EP, ependyma of third ventricle; P, portal vessels; PD, pars distalis.

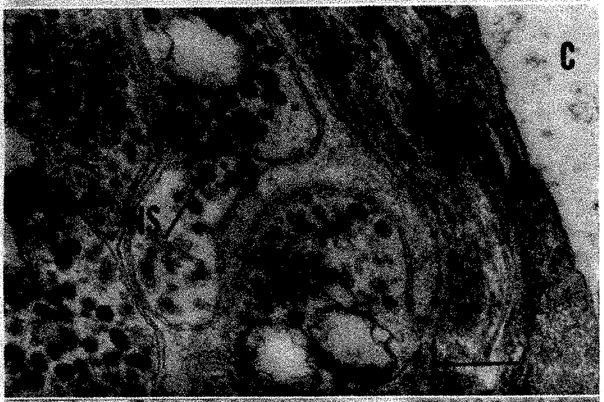

Fig. 2. Electronmicrograph of median eminence. Line at lower right indicates 0·5μ. C, Capillary lumen; E, endothelium; PC, pericapillary space; NS, neurosecretory granule.

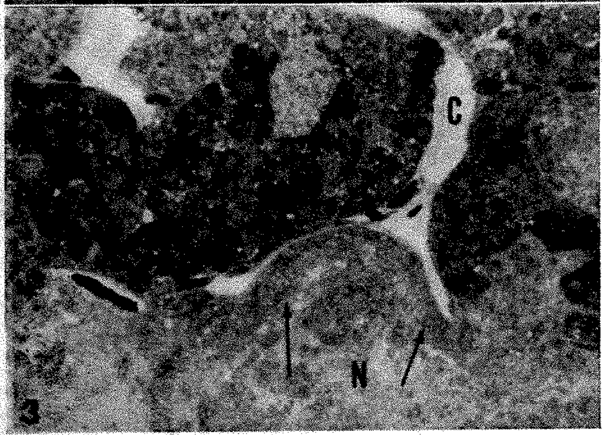

Fig. 3. Araldite 0·5μ thick section of pars intermedia, PI, and neurohypophysis, N. Arrows indicate concentration of neurosecretory material about capillary lumina.

In addition to a median eminence and hypothalamo–hypophysial portal system similar to that of amphibians, there are specialized pericapillary neurohaemal contacts within the neurohypophysis. These are similar to the neurohaemal contacts of the pars nervosa of the amphibian pituitary gland (Fig. 3). Electronmicroscopy of these areas reveals elementary neurosecretory granules measuring 1500–2000 Å and of lesser electron density than those of the median eminence.

Typical piscine features of the pituitary gland of *Calamoichthys* are the interdigitation of pars intermedia and neurohypophysis, and the presence of a saccus vasculosus with Kroenchenzellen.

Calamoichthys apparently retains the primitive hypothalamo–hypophysial portal system, a feature which it shares in a modified form with the elasmobranchs, chimaeras, lungfish and tetrapods. The loss of the portal system in ganoid and teleost fishes may be a secondary feature, associated with the evolutionary trend toward direct neurosecretory and secretomotor innervation of the pituitary gland in the latter group[13,14].

Biological Action of Blood Serum of Schizophrenic Patients in relation to Stress

THE presence in the blood of toxic substances, the action of which on the brain is presumed to cause disturbances in mental function, is frequently suggested as a factor in the pathogenesis of schizophrenia[1-4]. The sources and the chemical nature of such substances are still unknown. Many publications claim, however, that the body fluids, such as blood and urine, of schizophrenic patients show a wide spectrum of pathological activity on various test objects and the psychiatric literature usually refers to this as "toxic action". The body fluids of schizophrenic patients seem to change the functions not only of various processes in isolated biological systems (for example, isolated cells, tissue cultures and biochemical processes), but also the function of whole organisms.

It is not yet known, however, whether such reactions are specific or non-specific (for example, stress reactions). The non-specific reactions of the body fluids of schizophrenic patients have not been sufficiently investigated, although this question is of primary importance, especially in the study of responses in animals where the reaction to any injurious effect (for example, to the action of stressors) commonly includes many different patterns of adaptation-stress-reaction.

This communication presents the results of some investigations of stress reactions in animals to which blood serum from schizophrenic patients had been administered.

The experiments were carried out with rabbits and rats. The serum was administered intravenously to rabbits in a dose of 3 ml./kg body weight and a dose of 10 ml./kg body weight to rats. Sera from sixty-four patients with periodic schizophrenia, from fifty-six patients with nuclear schizophrenia and from fifty-seven normal individuals were used. 11-Hydroxy-corticosteroids were estimated before administration of the serum and at 2·5 h intervals afterwards. Blood sugar and lymphocyte counts were also taken before injection and afterwards at intervals of 1, 2 and 2·5 h. After the animals had been killed, internal organs were examined and the concentrations of adrenaline and noradrenaline in the hypothalamic region of the brain were estimated. The concentrations of corticosteroids in the blood and catecholamines in the brain were determined by fluorimetric methods[5–7].

After the administration of serum from the normal controls in the rabbits, corticosteroids showed a rise in concentration after 1 h (at 2·5 h the concentration was 5·9 ± 1·0 mg/100 ml. $P < 0{\cdot}05$ compared with normal—3·8 ± 0·7 mg) and there was a fall in the lymphocyte count (after 2·5 h—55 per cent from the baseline, $P < 0{\cdot}001$). There was also a temporary hypoglycaemia (13 per cent below baseline). In the internal organs there was no severe alteration, and only a hyperaemia was observed. In the hypothalamus there was an increase in the adrenaline content of brain tissue; 0·32 mg/g compared with the normal 0·07 mg/g, $P < 0{\cdot}05$. These results are presented in Fig. 1: we suggest that they show the activation of the function of the hypothalamus–pituitary hypophysis–adrenal cortex system.

The structure, the extent and the degree of the reaction of the animals to the injection of serum from schizophrenic patients were all different and, moreover, some of the differences in reaction seemed to be related to the pattern of development of the disease (that is, whether it was periodic or nuclear).

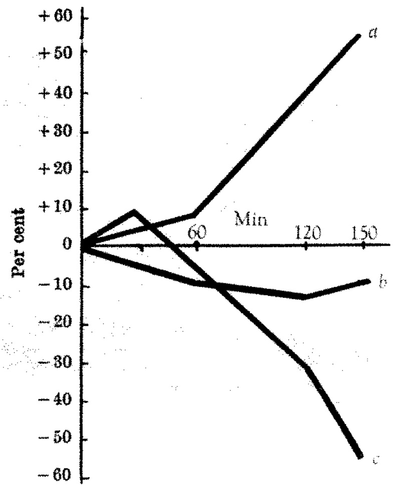

Fig. 1. Blood corticosteroids (*a*), sugar (*b*) and lymphocytes (*c*) after the administration of the serum of normal persons to rabbits.

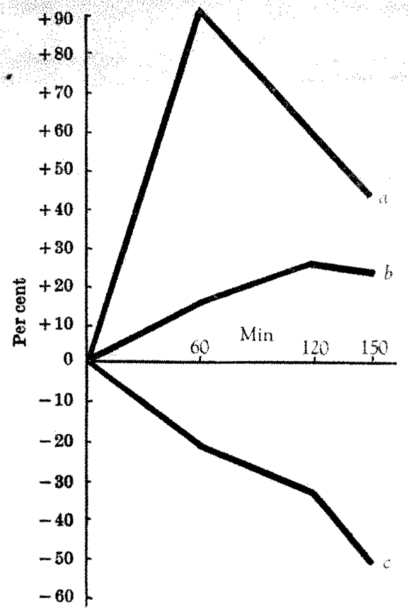

Fig. 2. Blood corticosteroids (*a*), sugar (*b*) and lymphocytes (*c*) after the administration of the serum of patients with periodic schizophrenia.

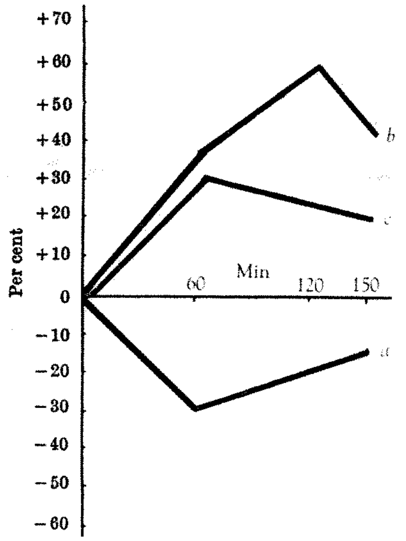

Fig. 3. Blood corticosteroids (*a*), sugar (*b*) and lymphocytes (*c*) after the administration of the serum of patients with nuclear schizophrenia to rabbits.

After the administration of serum from patients with periodic schizophrenia, a pattern of activation of the hypothalamic–hypophysis–adrenal cortex system was found similar to that after the injection of normal serum. There was a statistically significant increase in the concentration of corticosteroids after 1 h (1 h, 6·9 ± 1·1 mg/100 ml.; 2·5 h, 5·1 mg/100 ml., compared with a baseline of 3·6 ± 0·8 mg/100 ml.) and a fall in lymphocytes (after 2·5 h to 50 per cent of the baseline, $P < 0{\cdot}001$). In this group, however, a rise of 15–20 per cent in blood sugar was observed as well as the lymphopenia and this was assumed to be a corticoid hyperglycaemia because of the statistical correlation between the two reactions (Fig. 2). In this group there was also a statistical augmentation in the hypothalamus not only of adrenaline but also of non-adrenaline (non-adrenaline was 1·07 mg compared with 0·43 mg in normal animals). On examination of the internal organs a hyperaemia associated with very small haemorrhages along the intestinal tract was observed, especially in the diverticuli

After administration of serum from patients with nuclear schizophrenia (that is, schizophrenia with a gradual and malignant progress) the reaction pattern in the rabbits was different again The most important difference was the absence of any augmentation of the concentration of corticosteroids as well as the absence of a lymphopenic reaction (Fig 3) In these cases, typical stress reactions were not obtained, and in the hypothalamic region there was no increase in catecholamines In some cases, however, there were marked changes in the internal organs, consisting of massive haemorrhages and sometimes small ulcers especially along the intestinal tract Furthermore, sometimes in this group, there was a marked stable hyperglycaemia (up to 100 per cent of the normal) Similar results were found in the experiments on rats

These features of animal stress reaction to the administration of serum from patients with different forms of the disease could have great importance not only for the interpretation of the biological ("toxic") action of the serum of schizophrenic patients, but also in providing clues concerning the pathogenesis of this disease and providing an understanding of some of the clinical–somatic symptoms

Relationship between Total Body and Muscle Respiratory Rates in Infants with Malnutrition

Montgomery[1] and Monckeberg[2] have observed altered levels of oxygen consumption by malnourished infants before and during therapy of nutritional deficits There are indirect indications of changes in tissue oxygen metabolism in malnourished children Glucose tolerance tests reveal delayed clearance of intravenous glucose loads[3–4] It has been found that the malnourished infant has a reduced ability to utilize acetate, glucose and pyruvate when these were administered as ^{14}C isotopes[5].

There have been several enzyme studies of liver and muscle tissue from malnourished children[6–14] As previously noted[12], the study of isolated enzymes *in vitro* may have little bearing on the altered physiology of malnutrition *in vivo*. There is greater physiological significance in work on *in vitro* activities of enzyme chains or coupled reactions which are dependent on structural integrity[10] We have compared the oxygen uptake of skeletal muscle with the total metabolic rate of infants recovering from malnutrition

The infants varied in age from 8 to 30 months The clinical characteristics of infantile malnutrition in Jamaica have already been described[1,15].

The fasting infant was lightly sedated with chloral hydrate or paraldehyde Oxygen consumption was determined in an open system while the subject slept A constant flow of room air was maintained for 30 minutes through the system A portion of the effluent air was analysed for oxygen with an oxygen cell and for carbon dioxide by a manometric technique For comparison with tissue respiratory rates, the basal oxygen consumption is expressed as QO_2, ml O_2/kg tissue/h

Table 1 EFFECT OF MALNUTRITION ON OXYGEN CONSUMPTION

	Total body (mequiv /kg)	No of observations	QO_2 µl /mg wet wt/h Body	QO_2 µl /mg wet wt/h Muscle	QO_2 µl /mg protein/h Muscle
A	Less than 30	2	0 29	0 32	3 73
B	30 to 40	10	0 43 ± 0 03	0 35 ± 0 04	8 12 ± 1 88
C	Greater than 40	12*	0 59 ± 0 03	0 59 ± 0 08	7 43 ± 1 28
	P value (difference between groups *B* and *C*)		0 02	0 001	0 05

* Total body potassium was determined on only six of these subjects The others had completely recovered from malnutrition and are assumed to be in the normal range of total body potassium In this analysis the average of duplicate QO_2 determinations was utilized Means and standard error are given

Muscle samples weighing 10–20 mg were obtained by needle biopsy of the quadriceps muscle[12] within 2 h of the measurement of basal oxygen consumption. After weighing, the biopsy sample was homogenized by hand in 0 05 ml of 0·25 molar sucrose The glass homogenizer was kept in a brass block on ice The homogenate was centrifuged for 5 min at approximately 300*g* at 5° C and the supernatant was used for measurement of oxygen consumption Protein content of the homogenate was determined by the method of Lowry *et al* [17].

Tissue respiration was measured in duplicate by the cartesian diver method[10] The reaction mixture consisted of equal parts of potassium phosphate buffer (*p*H 7 4), magnesium chloride (0 2 molar) and sodium succinate (0·3 molar) After a 5 min equilibration period, three manometric readings were obtained at 10 min intervals and averaged to determine the rate of respiration Results were calculated as ml of O_2/kg wet weight/h (QO_2/wet weight) and µl. of O_2/mg protein/h (QO_2/protein).

Whole body potassium was measured in a 4 π whole body counter described by Garrow[16]. The subjects were counted to an accuracy of 6 per cent and the results corrected for self absorption

The total body potassium content can be used as one index of the degree of malnutrition These values were used to group the subjects in Table 1. A significant difference was observed between groups *B* and *C*, the two groups large enough for statistical evaluation Both the muscle and total body QO_2/wet weight were reduced in the subjects with reduced total body potassium No reduction in muscle QO_2/protein content of homogenate supernatant was seen

There is a correlation between basal oxygen consumption of the body and *in vitro* QO_2/wet weight With twenty-three duplicate samples the correlation coefficient was 0 525 The relation is described by $Y = 23 + 0\ 84X$, where 23 is the Y intercept and 0 84 is the computed slope, the points are plotted in Fig 1

A significant decrease in muscle respiration occurs in malnourished children It is proportional to the change in basal metabolic rate The fluctuations in oxygen consumption of the malnourished infants[1–2] are therefore related to alterations within tissues as well as altered respiring tissue mass

Succinate dehydrogenase is localized in mitochondria[20] The observed alterations in tissue respiration may be linked to alterations in muscle mitochondrial content Montgomery[19] demonstrated that a reduction in muscle cytoplasm occurs in severe malnutrition It is reasonable to assume that the number of mitochondria is also reduced The results could be explained by depletion of mitochondria because the oxygen consumption per mg protein (that is, per mitochondrion) is unchanged by malnutrition We cannot, however, rule out the possibility of the inhibition of mitochondrial respiration

In healthy adults, muscle oxygen consumption accounts for only 25 per cent of basal energy expenditure[21] In malnourished children, muscle mass/kg body weight is reduced to half compared with that of the adult[15] Muscle metabolism must account for only a small fraction of basal metabolism of the malnourished child

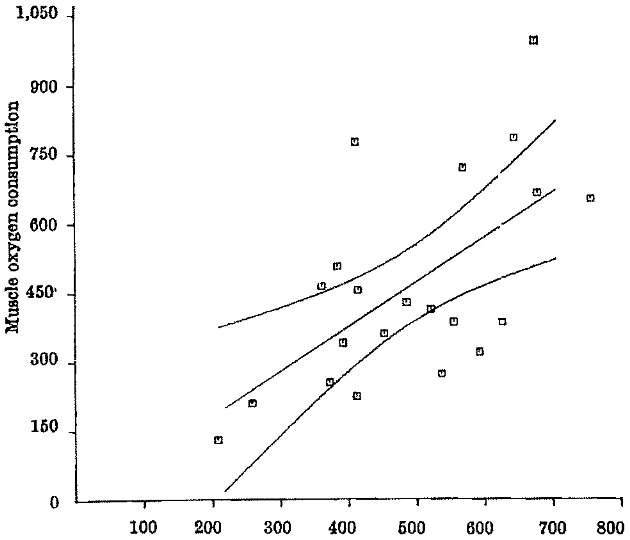

Fig 1 The relationship between *in vitro* muscle and *in vivo* total body oxygen consumption in infants recovering from malnutrition The points are means of duplicate observations on muscle homogenate The calculated slope and 94 per cent confidence limits are indicated on the graph

Because of the demonstrated relationship to total oxygen consumption, the alterations in muscle respiration must reflect alterations in other tissues

Waterlow[10] studied liver homogenate respiration with the same techniques in a similar group of malnourished children No significant alterations in succinate oxidation, based on fat-free dry weight, were observed Data from chemical analyses of the liver from malnourished children[22] reveal smaller changes in the K to N ratio than those seen in muscle[23] Sparing of the liver may be at the expense of muscle depletion We suggested that muscle has a buffering capacity against depletion of liver potassium and possibly other vital viscera[23]. This biological "law" has been proposed by Levinson and Watkin[24] and Waterlow and Stephen[25] for nitrogen homeostasis It may be true for tissue respiration as well as for electrolyte metabolism

BIOLOGY

Interoceanic Colonization of a Marine Goby through the Panama Canal

THE Panama Canal (Fig 1) represents a potential pathway for the interoceanic dispersal of marine fishes The fresh waters of Lakes Gatun and Miraflores have, however, effectively maintained the isolation of all but a few, of the marine shore fishes which are found on both coasts of the isthmus, those species which are able to cross this barrier are not known to breed on the opposite coast[1]

The neotropical genus *Lophogobius* is represented in Panama by two species, *Lophogobius cristulatus* (Ginsburg) from the Pacific coast of Panama and Costa Rica and *Lophogobius cyprinoides* (Pallas) which is widespread throughout the Caribbean We report here a breeding population of *L cyprinoides* in the Pacific, and examine some aspects of this successful colonization through the canal

The Miraflores Third Lock area (Fig 2), in which this population was found, is unique in many ways The Third Locks project was begun by the Panama Canal Company in 1941 in an effort to provide an auxiliary set of locks for the canal. When the project was abandoned in 1943, a large excavation 4,400 ft long, 300–500 ft wide and 60–85 ft deep was left adjacent to the Pacific entrance of the Canal The excavation was filled with sea water from the nearby canal entrance and with fresh water from run-offs At present the exchange of water between this lagoon and Panama Bay is maintained only at high tides by means of several underground culverts As a result of this arrangement the water in the Third Lock is brackish, being about 12‰ at the surface and 18‰ at 50 ft This is in contrast to the figure of approximately 30‰ in adjacent areas of Panama Bay The Third Lock experiences only a few inches rise and fall of water level as compared with the Pacific tidal oscillation which averages 16 ft This relatively low tidal amplitude is analogous to that found on the Atlantic coast where the average tidal range is less than 1 ft The steep basalt sides of the Third Lock are covered with oyster shells which provide the major habitat for *Lophogobius* The presence of adherent oyster shells in a non-tidal situation is unusual on the Pacific coast; in most cases, their periodic exposure during low tides renders them unsuitable cover for fishes.

Lophogobius cyprinoides seems to be the dominant species in the Third Lock Other goby and eleotrid genera, centropomids and lutjanids are sometimes found along the occasional shallow mangrove areas, but only the latter group seem to be present in significant numbers

Numerous individuals of *Lophogobius* from the Third Lock and Atlantic localities were examined to determine whether any morphological differences existed between the two populations The evidence indicated that the specimens from both localities constituted one homogeneous population

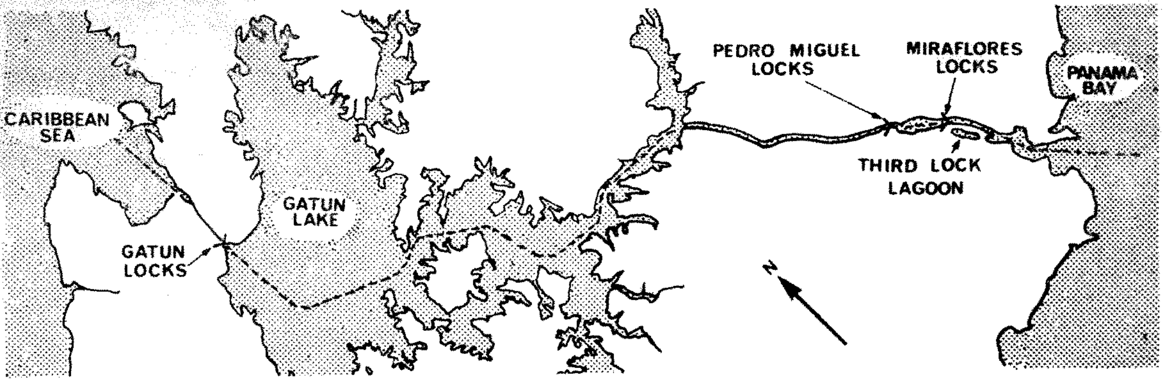

Fig. 1. The Panama Canal. The distance between the Atlantic and Pacific termini is approximately 50 miles.

Breeding tests were designed to detect the presence of any reproductive isolating mechanisms which could have evolved in these two groups. Control pairs of *L. cyprinoides* from both localities as well as pairs of the Pacific species *L. cristulatus* were established in 10 and 20 gallon aquaria which were continuously supplied with running sea water. Pairs of the six possible combinations between these three populations were also isolated. Fishes were fed minced shrimp and clams daily and each pair was provided with a triangular clay tile nest site. The results of these breeding experiments are summarized in Table 1. All the control groups, particularly those of *L. cyprinoides*, bred freely in the laboratory. All the crosses between individuals of *L. cyprinoides* from the Atlantic and Pacific localities produced frequent spawnings. No spawnings were obtained from the hybrid pairs of *L. cyprinoides* × *L. cristulatus*. This is not surprising because *L. cristulatus* is morphologically quite distinct from *L. cyprinoides*. It does indicate, however, that species of *Lophogobius* are unlikely to spawn indiscriminately when confronted with a no-choice mating situation. The larvae of both control (Atlantic × Atlantic) and experimental (Atlantic × Third Lock) spawnings of *L. cyprinoides* have now been raised past metamorphosis with no apparent differences in viability. It should be possible to determine the fertility of the F_1 generation in order to investigate further the presence of possible incipient genetic differences between the parental and colonizing population of *L. cyprinoides*.

Table 1. RESULTS OF BREEDING EXPERIMENTS WITH PANAMANIAN SPECIES OF *Lophogobius*

Species crossed	No. of pairs examined	Total days paired	No. of spawnings observed
L. cyprinoides × *L. cyprinoides* Atlantic Atlantic	3	167	12
L. cyprinoides × *L. cyprinoides* Third Lock Third Lock	2	90	10
L. cristulatus × *L. cristulatus* Pacific Pacific	7	371	5
L. cyprinoides × *L. cyprinoides* Atlantic Third Lock	5	286	22
L. cristulatus × *L. cyprinoides* Pacific Atlantic	3	311	0
L. cristulatus × *L. cyprinoides* Pacific Third Lock	3	160	0

This is the first record of a species of fish passing through the Panama Canal and successfully colonizing the opposite coast. The fauna of this region is not well known, however, and therefore it is quite possible that a careful survey would reveal other similar cases of successful amphi-American migrations. The success of *L. cyprinoides* in colonizing the Miraflores Third Lock and its failure to colonize other areas along the Pacific coast may be the result of a number of factors. When it was completed, the Third Lock represented an unoccupied habitat with a relatively large area capable of supporting demersal fishes. A euryhaline species such as *L. cyprinoides* was pre-adapted to colonize successfully a brackish water area[2,3]. At the same time the reduced salinity of this area undoubtedly prevented many of the stenohaline species which inhabit adjacent areas of Panama Bay from invading the Third Lock. The lack of competition from other bottom dwelling species, particularly Blennidae and Gobiidae, could account for the dense population of *L. cyprinoides*. In spite of the abundance of *L. cyprinoides* in the Third Lock, the species does not seem to have dispersed further into adjacent Pacific coastal areas. The factor limiting their distribution could be the lack of a suitable unoccupied niche rather than either the inability of the species to adapt to the Pacific environment or the fact that the numbers of individuals are insufficient to constitute a propagule. No indications of any morphological changes or presence of reproductive isolating

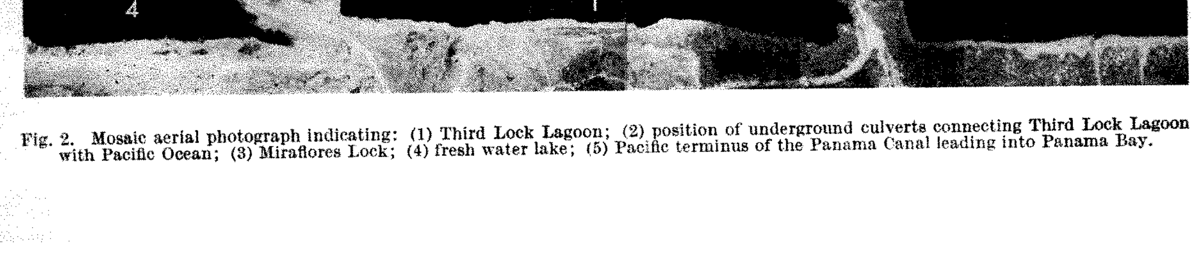

Fig. 2. Mosaic aerial photograph indicating: (1) Third Lock Lagoon; (2) position of underground culverts connecting Third Lock Lagoon with Pacific Ocean; (3) Miraflores Lock; (4) fresh water lake; (5) Pacific terminus of the Panama Canal leading into Panama Bay.

mechanisms were found, and at present the colonizing population seems to be identical to the parental stock. This is not surprising because the founding population could have been large and only a short isolation period has elapsed. Indeed, it is quite probable that gene flow is still maintained through the canal.

Differences in the Quality of Birds nesting in the Centre and on the Edges of a Colony

IN many bird colonies there is a surplus of adult birds in or about the colony which fail to breed[1,2]. In several species, the failure to breed can be attributed to the inability to obtain a suitable nest-site within the colony limits, and this results in competition for the limited number of available sites. Experiments on the kittiwake *Rissa tridactyla* have shown that some of these non-breeding adults will breed if suitable unoccupied ledges are made available in the centre of the colony, but similar sites remain unused on the periphery (Coulson, in preparation). This and other observations indicate that the competition among males, which are responsible for nest-site selection, is more intense in the colony centre and investigations were made to determine whether the birds nesting centrally in the colony differed in quality from those breeding near the edge.

The kittiwake colony at North Shields, Northumberland has been studied in detail during the past 15 years and all the birds have been individually marked for recognition[4]. For purposes of analysis, the colony has been divided into two sections, the centre and the edge, according to the position and density of the nests. The adult mortality rates and breeding biology of these two groups have been compared.

Mortality rates have been estimated from the disappearance of marked birds. The breeding birds show a very strong site and colony tenacity[3], and there is no evidence of birds moving from colony to colony. The annual mortality rates of male and female kittiwakes breeding in the centre and on the edge of the colony are shown in Table 1. The mortality rate among males nesting on the edge is about 60 per cent higher than in those nesting in the centre, but the difference between the two groups of females is not significant. This differential mortality could result from differences in the conditions in the two areas, or it could be caused by a selection of birds at the time of recruitment into the two areas. There is no indication that "stress" is greater at the edge of the colony; there is considerable evidence suggesting the opposite. The weight of males at the time of first breeding differs by a small but significant amount between the two areas (Table 2), but there is no such difference in the females, nor is there a significant difference between the mean wing lengths of the males. Those males recruited to the edge appear to be of a similar structural size to those which enter the centre of the colony, but they differ slightly in the quantity (and perhaps quality) of certain body tissues.

Table 1. MEAN ANNUAL MORTALITY RATES OF MALE AND FEMALE KITTIWAKES NESTING AT THE EDGE AND IN THE CENTRE OF THE COLONY

	Centre			Edge		
	No. of bird-years at risk	No. dying	Percentage mortality	No. of bird-years at risk	No. dying	Percentage mortality
Males	404	47	11·6	307	57	18·6
			($\chi^2 = 6·17$, 1 d.f. $P < 0·02$)			
Females	412	34	8·3	332	38	11·4
			($\chi^2 = 2·15$, 1 d.f. Not significant)			

Table 2. WEIGHTS AND WING LENGTHS OF MALE AND FEMALE KITTIWAKES BREEDING IN THE CENTRE AND ON THE EDGE OF A COLONY

	Centre			Edge			
	No.	Mean weight (g)	*S.E.*	No.	Mean weight (g)	*S.E.*	Difference (centre edge)
Males							
All breeding birds	108	393·5	±2·1	105	385·9	±2·0	+7·6*
Survived more than 5 yr	36	397	±4·1	28	391	±4·9	+6·0
Died within 5 yr	53	388	±3·4	51	383	±2·9	+5·0

Survived more than 5 yr	27	358	±5·2	21	360	±7·0	−2·0
Died within 5 yr	37	345	±3·5	43	344	±4·4	−1·0
Mean wing length	93	299·8	±0·88	94	301·8	±0·74	−2·0

* $P < 0·01$.

All weights and measurements were taken during the first year of breeding.

Table 2 shows that both the male and female kittiwakes which survive 5 years or more from the time of first breeding are significantly heavier at the time of recruitment than their neighbours which died within this period ($P < 0·01$ in each sex). It seems that subsequent survival is partly related to the body weight at the time of recruitment. It is possible to account for much of the observed differential mortality between males breeding on the edge and in the middle of the colony because of the higher proportion of low weight males recruited at the edge of the colony. The intense competition for nest sites in the centre results in very high selection for vigorous males with less severe selection towards the edge of the colony.

Other aspects of the breeding biology of the kittiwakes in the two areas show significant differences. There are a larger mean clutch size, higher hatching success and more young fledged per pair in the centre of the colony (Table 3). There is also a large difference in the proportion of birds which change their mate from one breeding season to the next. It has been shown that breeding success is lower among kittiwakes which are forming the particular pair for the first time and that age also influences the fecundity[4]. More investigations are required to establish the role of these factors in producing the differences in the breeding biology shown in Table 3. The differences in the reproductive rate, however, between birds breeding in the centre and on the edge of the colony seem to be the direct or indirect result of variations in the quality of the males recruited in different parts of the colony. None of the differences were the result of predation.

These results have important implications in ecological studies on colonial birds and in understanding colonial organization. It is important to study representative samples of birds when measuring the mortality rates of colonial birds and also when estimating the mean reproductive success of the species. These findings also suggest that the adult birds which fail to obtain a breeding site may be individuals of even poorer quality than those which succeed in acquiring an edge site. If this is the case, it would seem probable that their survival rate may be much lower than any group of breeding birds and the loss to the population of this breeding potential may not

Table 3. COMPARISON OF THE BREEDING BIOLOGY OF KITTIWAKES BREEDING ON THE EDGE AND IN THE CENTRE OF THE COLONY

	Centre	Edge
No. of nests	433	323
Clutch size	2·18 ± 0·024	2·03 ± 0·028*
Hatching success	76 ± 1·4 per cent	70 ± 1·8 per cent*
Breeding success	68 per cent	65 per cent
Young fledged/pair	1·48	1·32*
Per cent change mate/year	29 per cent	54 per cent*
Mean date of first egg	May 16	May 20*

* $P < 0·01$.

be as great as would appear from proportions of adult non-breeding birds.

Chemical Protection against X-irradiation by a New Reducing Agent 1,4-Dithiothreitol in Marsupial Leucocytes in Culture

THE sulphydryl compounds[1] are among the most effective and useful groups of chemicals with a protective action against the damaging effects of X-rays in living organisms. In 1964, dithiothreitol (DTT) was put forward by Cleland[2] as a new protective agent for sulphydryl groups against oxidation. Because DTT is a solid with high solubility in water with a very low vapour pressure and little tendency to be oxidized by air, it should be superior in these respects to the thiols already in use, some of which are sparingly soluble or have an objectionable smell[2]. No data have been reported on DTT as a protective agent against irradiation damage, for which it would seem to be particularly well suited. We have irradiated leucocyte cultures of the potoroo *Potorous tridactylus* in the presence and absence of DTT to determine the protective action of DTT against induced chromosome breakage.

The low chromosome numbers (2n = 13 in male and 12 in female) and the distinct morphology of the potoroo chromosomes enable an accurate estimation of damage at metaphase to be made. Translocations involving two or more chromosomes can be recognized without ambiguity.

Leucocyte cultures were prepared from oxygenated blood obtained from an anaesthetized potoroo by heart puncture using an intraperitoneal injection of 60 mg/ml. of 'Nembutal' (1 ml./4 lb. body weight). Samples of 5 ml., half of which received 0·5 ml. of DTT (0·1 mg of DTT/ml. of whole blood) 1 h before irradiation, were irradiated with 200 r. at 100 r./min (half value layer 0·5 mm copper; 235 kV peak). Treated and control cultures were kept at room temperature. One hour later, all blood samples were mixed with a few drops of phytohaemagglutinin (PHA, Wellcome) and after a few minutes the samples were centrifuged for 5 min at 100*g*. The supernatant plasma with suspended leucocytes was removed, and the leucocytes precipitated by centrifuging for 7 min at 100*g*. The supernatant was discarded and the cells were washed twice in complete medium to remove traces of DTT and autologous serum. A sample (0·5 ml.) of complete medium was added to each sample of washed leucocytes from 5 ml. of blood; the cells were dispersed and were placed in culture flasks with 8 ml. of complete medium (Parker's 199, 12 per cent foetal calf serum and 2 per cent PHA). DTT solution was made by dissolving 50 mg of dithiothreitol (Cleland's reagent, Calbiochem) in 50 ml. of Hanks balanced salt solution (BSS) sterilized by filtration. Cultures were incubated for 72 h at 37° C with 'Colcemid' (Ciba) added for the last 2 h of the culture period to give a final concentration of 0·004 per cent. Leishman microscopic preparations were made after hypotonic treatment and fixation (1 glacial acetic : 3 ethanol).

Table 1. CHROMOSOME DAMAGE IN LEUCOCYTE CULTURES FROM X-IRRADIATED FULLY OXYGENATED BLOOD OF *Potorous* WITH AND WITHOUT DITHIOTHREITOL

	X-rays	DTT	Chromatid deletions	Chromosome deletions	Two-hit events, chromosome	Cells scored
DDT treatment	+	+	5	66	5	100
	+	+	2	63	7	100
	+	+	2	62	10	100
Mean	+	+	3	64 ± 1·01	7 ± 1·4	300
DTT control	+	−	10	79	18	100
	+	−	8	70	26	100
Mean	+	−	9	75 ± 4·5	22 ± 4·0	200
Spontaneous aberration	−	−	2	12	0	100
Mean*	−	−	7 ± 1·6	12 ± 1·4	0	400

* Mean for parallel controls done at other times but in similar conditions. X-ray dose was 200 r. at a rate of 100 r./min; DTT dose was 0·1 mg/ml. whole blood.

All cultures gave good mitotic indices and chromosomal damage was noted as follows: chromatid and iso-chromatid deletions were taken as one-hit events, and chromosomal interchanges, such as conjugation of an acentric pair with another chromosome, rings and dicentrics, were noted as two-hit events.

All the damage can be expected to be chromosomal because all the cells were irradiated in G_1. Spontaneous aberration, however, will produce chromatid deletions and some iso-chromatid deletions. Some iso-chromatid deletions are indistinguishable from chromosome deletion produced by irradiation. In Table 1 the level of spontaneous breakage is shown in concurrent control cultures and in parallel controls made at different times. It is clear that there is no significance in the chromatid deletions produced by spontaneous breakage. Significant differences, however, occur in the number of aberrations of the chromosome type. The presence of DTT significantly decreases chromosome aberrations in irradiated cultures; the chromosome deletions are reduced by 17 per cent and the two-hit events by as much as 68 per cent. If the damage is calculated as the number of hits per cell, then the presence of DTT during irradiation reduces the total damage by a half (Table 2).

Table 2. PROTECTION AGAINST X-RAY INDUCED CHROMOSOME BREAKAGE BY DITHIOTHREITOL

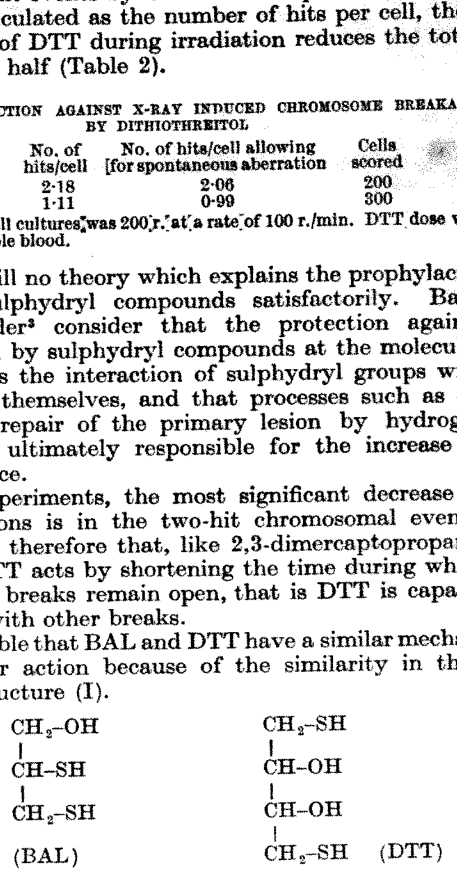
DTT present	No. of hits/cell	No. of hits/cell allowing [for spontaneous aberration	Cells scored
−	2·18	2·06	200
+	1·11	0·99	300

X-ray dose to all cultures was 200 r. at a rate of 100 r./min. DTT dose was 0·1 mg/ml. of whole blood.

There is still no theory which explains the prophylactic action of sulphydryl compounds satisfactorily. Bacq and Alexander[3] consider that the protection against X-irradiation by sulphydryl compounds at the molecular level involves the interaction of sulphydryl groups with the radicals themselves, and that processes such as instantaneous repair of the primary lesion by hydrogen transfer are ultimately responsible for the increase in radioresistance.

In our experiments, the most significant decrease in the aberrations is in the two-hit chromosomal events. It is possible therefore that, like 2,3-dimercaptopropanol (BAL)[4,5], DTT acts by shortening the time during which chromosome breaks remain open, that is DTT is capable of reacting with other breaks.

It is probable that BAL and DTT have a similar mechanism for their action because of the similarity in their chemical structure (I).



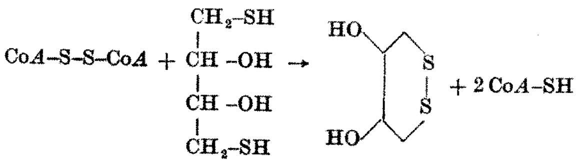
$$\begin{array}{c} CH_2\text{–}OH \\ | \\ CH\text{–}SH \\ | \\ CH_2\text{–}SH \\ \\ \text{(BAL)} \end{array} \qquad \begin{array}{c} CH_2\text{–}SH \\ | \\ CH\text{–}OH \\ | \\ CH\text{–}OH \\ | \\ CH_2\text{–}SH \end{array} \quad \text{(DTT)} \quad \text{(I)}$$

Sulphydryl compounds may act by enhancing the process of repair[3,6]; for example, they convert a coenzyme *A* molecule (CoA-SH) in an inactivated state to a disulphide through a free radical oxidation[2].

$$\mathrm{Co}A\text{–S–S–Co}A + R\mathrm{SH} \rightarrow \mathrm{Co}A\text{–SH} + R\text{–S–S–Co}A \qquad (1)$$

$$R\text{–S–S–Co}A + R\mathrm{SH} \rightarrow R\text{–S–S–}R + \mathrm{Co}A\text{–SH} \qquad (2)$$

The molecule of DTT has two sulphydryl groups, and so it is twice as effective as the monothiols, and it should be more effective in the repair mechanism mentioned in equations (1) and (2), because the disulphide formed is a sterically favoured cyclic one (equation (3)).



CoA–S–S–CoA + CH₂–SH / CH –OH / CH –OH / CH₂–SH → HO, HO, S, S + 2 CoA–SH
(3)

This increases its effectiveness, giving it an even lower redox potential than that of BAL; DTT is capable of maintaining monothiols in the reduced state and reducing dithiols quantitatively[2].

If we are correct in assuming that BAL protects the processes of active oxidative metabolism necessary for the healing of broken chromosomes, then our results would imply that DTT had a similar action on rejoining. The simplest hypothesis is that DTT acts as a reducing agent by almost eliminating the oxygen effect, because it does not reduce the total damage by more than 50 per cent. Whatever the mechanism, dithiothreitol is an effective protector against ionizing radiation in living cells and it decreases all types of chromosomal breakage significantly. It would be valuable to make a direct comparison with BAL in the same cell system and also to determine (by establishing the optimum concentration and period of treatment) whether a 50 per cent reduction in damage is the limit of effectiveness.

We thank the Australian Institute of Nuclear Science and Engineering, which supported this work, and the Tasmanian Animals and Birds Protection Board for permission to obtain specimens of *Potorous tridactylus*.

Method for deriving a Survival Curve of Young Calves in Wild Ungulates

In animal demography attention is often drawn to the lack of data on very young animals[1,2], for the relatively delicate remains of juvenile corpses are easily destroyed or consumed by predators. The Uganda defassa waterbuck *Kobus defassa ungandae* Neumann, in the Queen Elizabeth Park, western Uganda, is continuously breeding and monotocous. In such an animal an approximate survival curve for the first 6 to 7 months of life can be constructed from the lactation status of the parent. Lactation state is determined by gross examination of the sliced mammary gland in slaughtered animals.

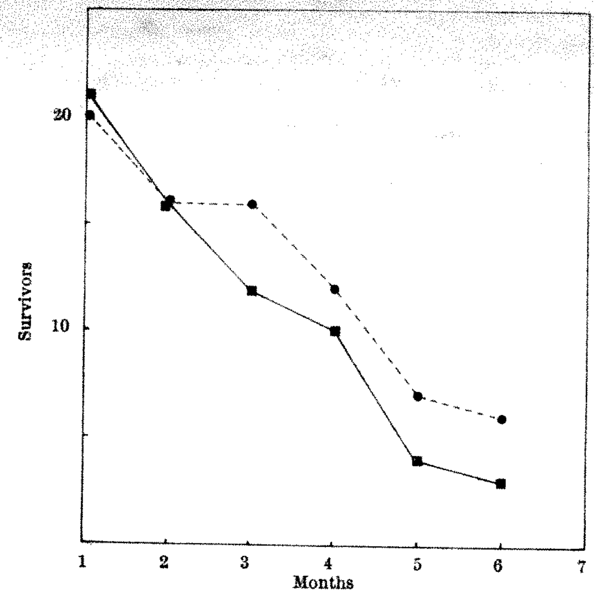

Fig. 1. Survival curves for the first six months of life in waterbuck calves derived from the numbers of lactating (■—■) and non-lactating (● - - - ●) females.

Females more than 3 years old are usually lactating up until the sixth month of pregnancy, or they have lost their calves. If one is not lactating, therefore, the month of pregnancy, determined in this study by using the method of Huggett and Widdas[3], suggests that the calf was lost sometime before that date. In the waterbuck, the time of occurrence of the post-partum oestrus is not known with certainty. It may be variable, although evidence suggests it to be about 21 days. Mating, followed by conception, usually occurs at this time. These variables mean that an arbitrary figure must be taken as a starting point. For the waterbuck, thirty days was considered a reasonable period. This figure was based on results obtained from slaughtered animals. Thus the month of gestation plus one month in non-lactating females tells us the age up to which the calf may have died (Table 1). Clearly if a female is four months pregnant and not lactating, the previous calf may have died at any time in the preceding five months. But the lactating animals also represent an l_x series in life table terminology, which shows the actual calf survivors alive at that time, for lactation terminates rapidly once suckling ceases. Plots of a d_x curve and an l_x curve, the former curve derived from non-lactating females and the latter from lactating, show that the curves are similar (Fig. 1). In practice, the l_x curve is the more reliable, for the only variable factor used in deriving it is the length of the post-partum delay before fertilization, whereas in the d_x curve there is the additional error in the determination of the date of death of the calf, which increases with increasing age of pregnancy.

Although it is not possible to confirm the accuracy of a life table derived by this method without reference to a large number of calves marked at birth, the estimated mortality of 49 per cent in the first six months of life, which this method gave, compared with estimates of 52 per cent and 56 per cent derived from methods of direct observation.

In continually breeding mammals the application of this method eliminates much of the guesswork previously applied to this sector of the survival curve.

This work was supported by a grant from the Science Research Council, and facilities were kindly

Table 1. LACTATION STATE OF FORTY-ONE FEMALES ACCORDING TO MONTH OF PREGNANCY

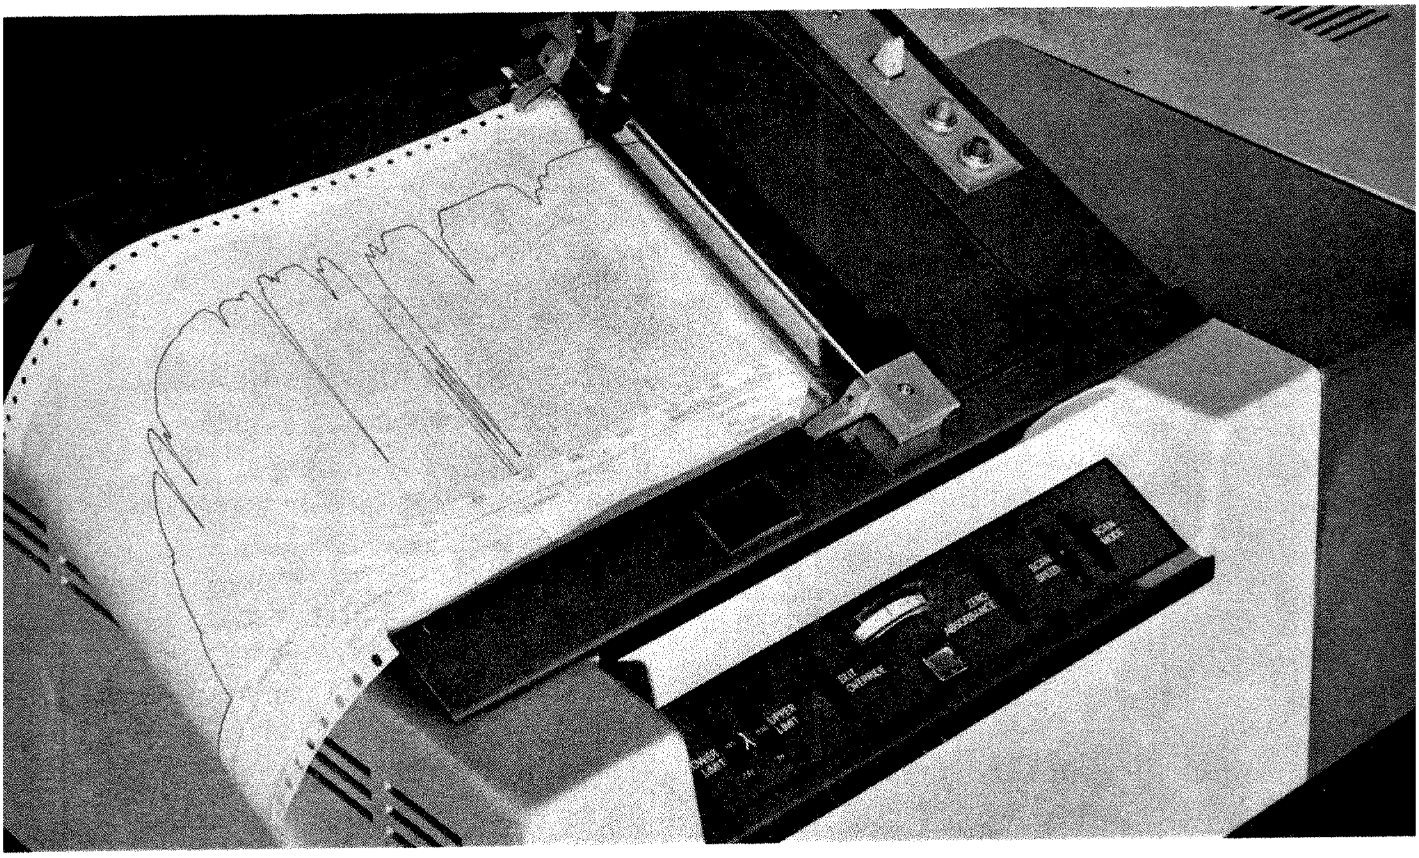
Set these controls on Perkin-Elmer's new U.V. Spectrophotometer and scan any wavelength range between 190—850 nm



Perkin-Elmer's new Model 02 Ultraviolet and Visible Spectrophotometer has a unique wavelength control system. By setting upper and ower limit stops, you can scan any wavelength range singly or repetitively and present the spectra sequenially or superimposed.

You can scan the full range rom 190 to 850 nm on a single chart in 2, 10 or 40 minutes.

You can expand the linear absorbance scale five times so that 0.3 absorbance units fills the chart.

You can perform kinetic studies at a fixed wavelength.

You can insert a new roll of paper into the flow chart recorder in 30 seconds and record 40 rull range spectra without changing it.

You can choose from a wide range of accessories including a thermostatted multiple sampling unit - ideal for enzyme reaction studies.

You can get faster, more accurate results over a larger range of applications with this highly automated instrument.

You can get details immediately from Perkin-Elmer Ltd. Beaconsfield, Bucks. Telephone: Beaconsfield 2571, Telex: 83257 or Manchester Central 2569.

CAMBRIDGE

An Introduction to Fluid Dynamics

G. K. BATCHELOR, F.R.S.

Aimed at giving the student a basic understanding of the dynamics of real fluids, this book makes forty years, research on flow systems and flow phenomena available to the undergraduate. It assumes no previous knowledge of fluid dynamics and the material has been selected to introduce the reader to the more important ideas and applications. Although the book is intended primarily for second, third and fourth year students of applied mathematics, it will also be useful to students starting graduate studies in mathematics.

APPLIED SCIENCE

Role of Austenite and Mineral Oil in Lubricant Failure

THE suggestion[1] that the failure of lubrication in gears is caused by the actual contact temperature reaching a critical value (150° to 200° C) at which the desorption of surface active compounds present in oils occurs has been supported[2] by evidence obtained from modified 'Bowden–Leben' friction apparatus. With mineral oils, the friction change could not be observed in this apparatus with a tool-steel friction pair, but it showed up sharply with stainless steel (18 per cent chromium, 8 per cent nickel). The mechanism of the difference between the two is the subject of this communication.

With a similar apparatus we used a steel (*EN* 39 *B*) which was chiefly bainite (hardness, Vickers pyramid number 440) but no austenite. In Fig. 1*A* the friction temperature curve, using an Admiralty turbine oil, *OEP*-90, and a tungsten carbide hemispherical slider, is shown. By gas carburizing and suitable quenching of the *EN* 39 *B* steel, the surface contained martensite and retained austenite. The friction temperature trace is shown in Fig. 1*B* for a 25 per cent retained austenite sample (Vickers pyramid number 740). A transition temperature shows up clearly, and Fig. 1*C* shows the friction temperature trace for a 5 per cent retained austenite sample (Vickers pyramid number 750). No sharp increase is found.

In carburized steel, the retained austenite content is highest just below the surface; the finish grinding of gears must often result in changes in austenite content, and the importance of this large change in the friction temperature characteristic, consequent on the presence of austenite, must be recognized in gear testing. The scuffing loads are extremely variable and such a scatter could well come from the change in austenite content. Niemann and Lechner[3] have demonstrated that alloys containing austenite reduce the load carrying capacity of gears.

The previous communication[2] did not give any reason for the transition temperature being absent in tool steel when using plain mineral oil (light stock). Mr A. Eyres suggested that the reactivity of the sulphur compounds usually present in plain oils should be studied.

We considered that sulphur compounds, for example, might react slowly with austenite but sufficiently rapidly with martensite so that, when the critical temperature was reached in the slow speed friction machine, physical desorption would be masked and a transition would not be seen. A similar mechanism would also occur for oils containing extreme pressure additives. In running machine parts, such as gear teeth, the ambient temperature is much lower than the total flash temperature achieved in the contact zone and the contact time is short; thus the reaction will not have occurred to the same extent, and a critical temperature will still be observed for martensitic steels and plain oils and, especially in the running-in period, where chemical reaction has occurred least, for oils containing extreme pressure additives.

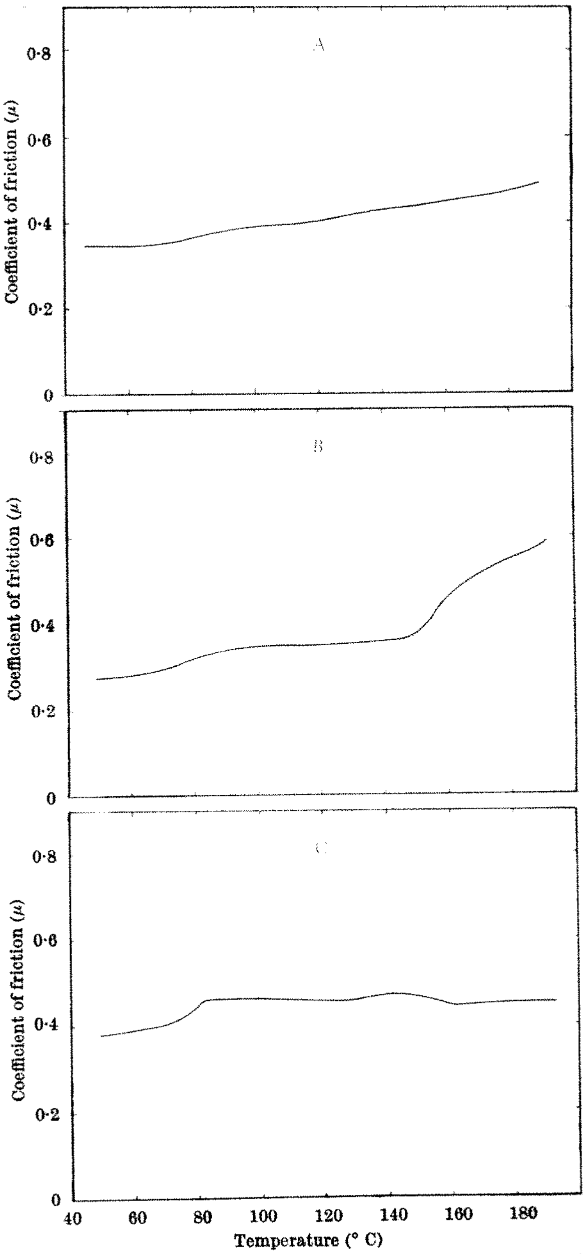

Fig. 1. *A*, Friction temperature curve using 'Bowden-Leben' machine (average of at least four traces) using a tungsten carbide slider and an uncarburized *EN* 39 *B* rider. Velocity, 0·02 cm/sec; load, 2·5 kg; turbine oil lubricant. *B*, Friction temperature curve using carburized *EN* 39 *B* with 25 per cent retained austenite; turbine oil lubricant. *C*, Friction temperature curve using carburized *EN* 39 *B* containing austenite only; turbine oil lubricant.

Groszek and Palmer[4] isolated surface active compounds present in oils by percolation through columns of activated magnesium oxide and reported that the compounds exist at a concentration of about 0·4 per cent and contain sulphur. No transition temperatures were obtained from the friction temperature curves for the 25 per cent retained austenite sample or uncarburized *EN* 39 *B* when using white oil (oil from which surface active compounds have been removed) lubricant, but when 0·59 per cent of the surface active compound was added to the white oil a quite different result was obtained for the two surfaces. The carburized steel containing retained austenite showed a critical temperature (Fig. 2), but the uncarburized steel gave no sharp critical temperature (Fig. 3). It is suggested that this effect is caused by some reactive compounds in the surfactant reacting faster with martensite than with austenite and thus excludes the possibility that the absence of a critical temperature was a result of oxidation products formed in the 'Bowden-Leben' system but not necessarily in gear and disk systems.

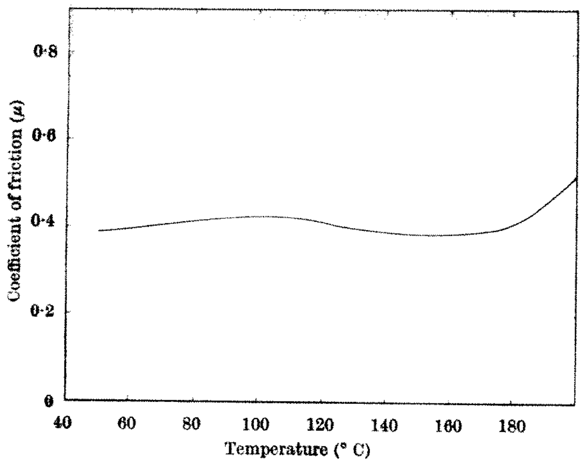

Fig. 2. Friction temperature curve using a tungsten carbide slider and a carburized *EN* 39 *B* steel rider containing 25 per cent retained austenite; lubricant, 0·59 per cent by weight surface active compound in white oil.

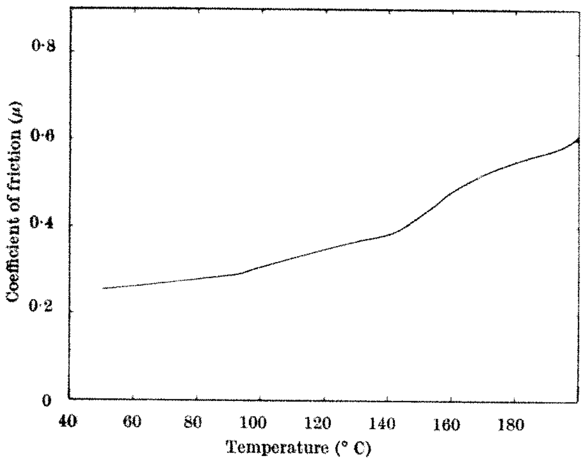

Fig. 3. Friction temperature curve using an uncarburized *EN* 39 *B* steel rider; lubricant, 0·59 per cent by weight surface active compound in white oil.

These findings are clearly very important for the choice of gear steels.

We thank A. Groszek for the surfactant, and the British Iron and Steel Research Association for carrying out the heat treatment and the X-ray determination of the austenite content. We also thank P. T. Holligan and Dr Bruce Kelley for many useful discussions. One of us (W. G.) thanks the Mobil Oil Co., Ltd., for the award of a bursary.

GENERAL

Test of the Alignment Hypothesis as the Reason for the Mosaic Unit Phenomenon

I HAVE reported[1,2] that ancient floor mosaic patterns tend to be certain absolute sizes (mosaic units), and I suggested[2] that the reason was practical.

There is (refs. 1–3 and unpublished work) a mathematical hypothesis—the alignment hypothesis—as follows. If particles, randomly drawn from a population of particles of sizes and shapes varied randomly within limits, are packed in adjacent rows, the probability of particles forming a line transversely through these rows is much higher at certain intervals than elsewhere (Fig. 1*A*).

We may (ref. 3 and unpublished work) have here the explanation of the mosaic unit phenomenon because the mosaic stones of ancient floors (ref. 3 and unpublished work) are usually of random varied sizes and shapes within limits, and there is varied evidence (refs. 2 to 5 and unpublished work) that the ancients usually placed stones without special selection, shaping or special spacing, usually as adjacent rows. Thus the mosaic patterns of the ancients would tend (if the alignment hypothesis is true) to turn out most regular when made to certain dimensions ("alignment intervals", see Fig. 1*B*), and they may have found this by experience.

There is close agreement (refs. 1 and 3 and unpublished work) between the typical sizes of ancient mosaic patterns and their sizes predicted from the alignment hypothesis; there is no more than 1 mm difference between the observed modal value ($\sigma = 1{\cdot}3$ mm, when $c = 1$ mm for $n > 10^4$) and the calculated value for each of the eleven most typical pattern sizes. This suggests that the alignment hypothesis works in reality.

If it does, "alignment" in the simple state of Fig. 1*A* should exist in unpatterned mosaics. I find that this is true; a frequency distribution of the distances between 257 pairs of these alignments is shown in Fig. 3. Moreover, they cluster about the commonest pattern sizes. Fig. 2*A* shows a typical case.

Fig. 1. Diagram of what is meant by alignment (*A*) showing also the use of alignments to a mosaicist (*B*).

Alignments have been demonstrated (work to be published) as a packing phenomenon in modern pebble floors, fish roes and other[2,3] materials, but a test to see if alignments occurred among cleaned ancient mosaic stones packed in the laboratory had not been attempted.

The simplest method of making this test is for a naive volunteer to place ancient mosaic stones (without special selection or spacing) in adjacent rows. Twenty-six aggregations about 50 cm long and six aggregations about 110 cm long were formed (five to ten rows wide). In twenty-eight aggregations, sixty-two alignments ran from one side to the other. The observed alignment intervals clustered at the predicted alignment intervals (Fig. 3).

I also laid stones myself (but in the dark so that I could not see the packing), using grooves to guide the production of sets of eight adjacent rows. Eighteen aggregations were about 32 cm long and two were about

55 cm long. Laying stones in daylight, I blocked my view of those already packed with a screen. Forty aggregations were about 55 cm long and eight were about 72 cm long. Removing the screen (and illuminating those done in darkness) showed alignments, passing through the full eight rows. Again, they clustered at the expected intervals (Fig. 3).

Human factors were eliminated as follows. Cleaned ancient mosaic stones were poured on to a grid of numbered squares. Volunteers moved the stones about until only one lay in each square. I then selected a random number by the conventional full technique[6] using random number tables[7,8]. The stone in the square with this number was removed and added to the rows, where it was packed tightly.

To decide which face of this stone should lie uppermost, I threw a die. If the result was one, I did not turn the stone, if two I turned the stone so that its face pointing towards the right hand side of the grid lay uppermost, and so on. (All the stones were faced to the sides of the grid by volunteers.)

The orientation of each stone was decided by tossing a coin. If "tails", it was turned clockwise through a right angle in the plane of the grid; if "heads", it was left. To decide which way around the stone should lie in this position, another toss was made. If "heads", the stone was revolved through 180° in the plane of the grid; if "tails", it was left. Twenty-five aggregations about 70 cm long resulted. Sixty-eight alignments ran through the full width of eight rows, and again clustered about the expected intervals. (There was no alignment in one aggregation.)

This method was slow, so I made a packing machine. Cleaned ancient mosaic stones fell from a hopper onto a conveyor belt, where they were constrained to form rows by strips tensioned along the length of the conveyor. They first passed under rubber flaps to make them lie flat, and were then packed by their progress being obstructed by a guillotine. Raising the guillotine cleared the channels for a fresh test.

One hundred and six aggregations were obtained (mean length 30 cm), with 234 alignments (passing through the full five rows), which clustered at the predicted intervals (Fig. 3). Fig. 2*B* shows a typical case. (There was no alignment in three aggregations.) More of the intervals agreed with the expected distances when each alignment was measured from the preceding alignment instead of from the start of the aggregation (Fig. 3). Some aggregations were short because tests were stopped if stones were forced up out of their channels, but they were always greater than 13 cm in length, and often were about 45 cm long (three ⩾ 115 cm).

These alignments occur among cleaned ancient mosaic stones packed without cement, and yet the typical

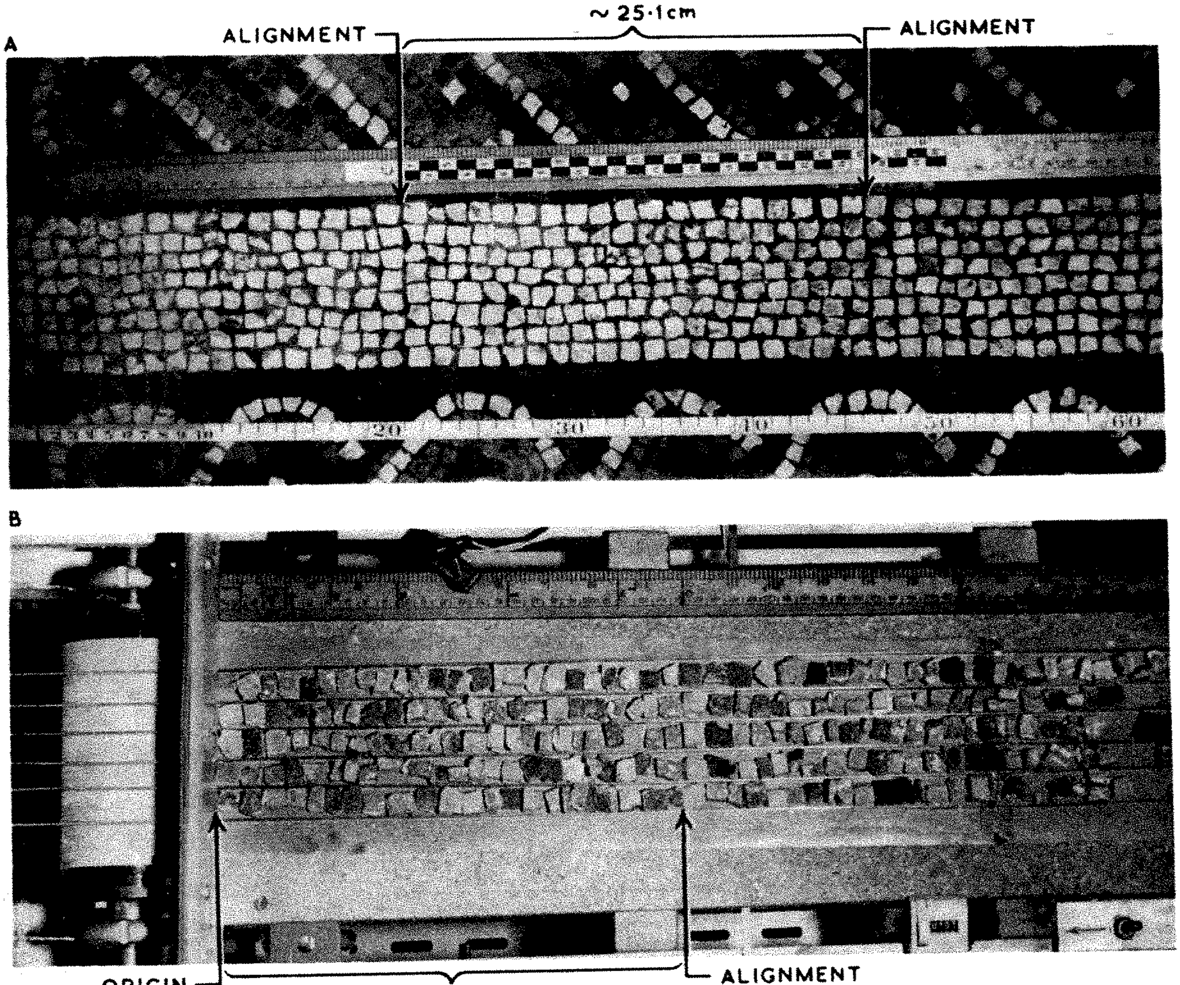

Fig. 2. Demonstration that the alignments observed in ancient mosaics can be produced experimentally, simply as a packing phenomenon. A typical interval of occurrence of an alignment occurred spontaneously among ancient mosaic stones randomly packed by machine (*B*). This coincided with a typical interval between alignments in an ancient mosaic (*A*) at Aldborough, Yorkshire (courtesy of the Ministry of Public Building and Works).

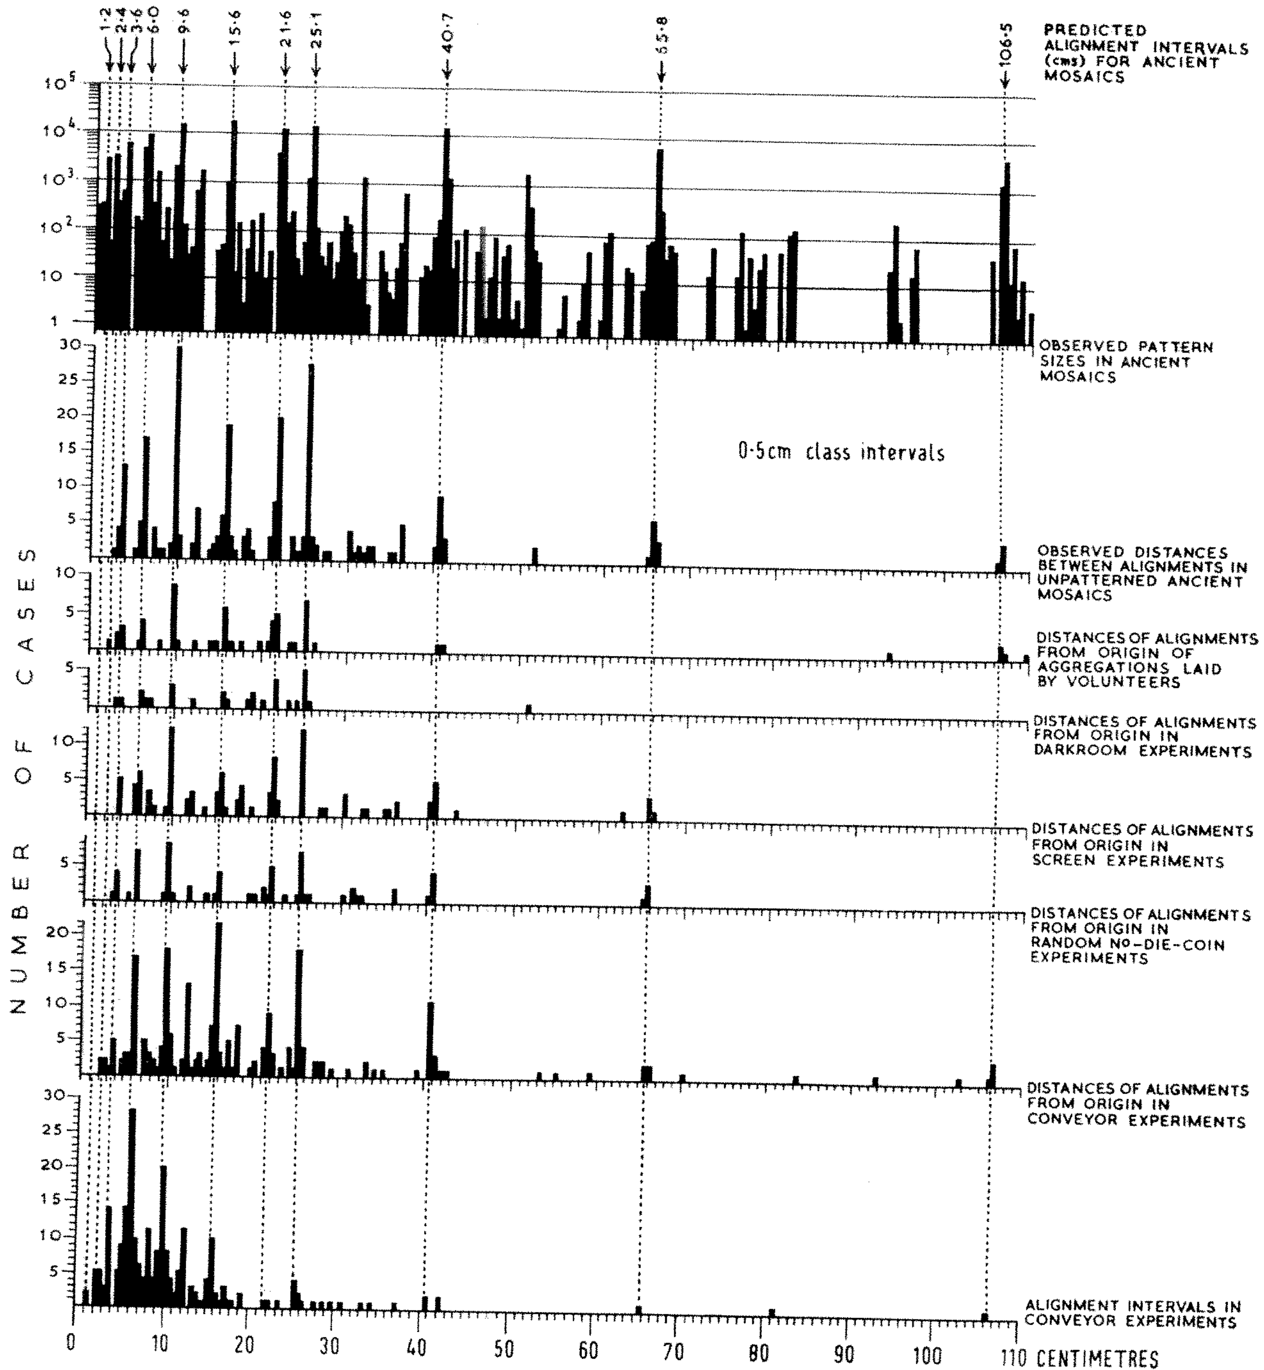

Fig. 3. Comparison of results of five experimental methods with the observed phenomena and with the intervals calculated from the alignment hypothesis.

intervals agree (Fig. 3) with the alignment intervals in ancient mosaics, in which stones are packed with cement. This supports the deduction that cement plays little part in stone packing.

While before[1-3,5], confirmation of the alignment hypothesis was observational, the existence of the alignments predicted by the alignment hypothesis has now been tested experimentally with mosaic stones and found to be true. The reason for the mosaic unit phenomenon seems to be the alignment phenomenon.

This is part of a project financed by a Leverhulme Research Award, for which I am grateful. I thank Professor Roger Warwick for support, and also Professor H. Kalmus and Professor E. R. Laithwaite. I also thank the British Museum Department of Greek and Roman Antiquities and the Ministero della Pubblica Istruzione for stones, the Goldsmiths' Company for aiding collection of specimens, and all volunteers.

The Correspondence of Isaac Newton

Vol. 4 1694–1709 Edited by J. F Scott Pp xxxii + 578 + 6 plates (London Cambridge University Press, 1967 Published for the Royal Society) 231*s*

One cannot say that the documents collected in the present volume of Newton's correspondence throw much new light on the course of his career during the period it spans, although this was the time when the most considerable event occurred in his public activity In 1696, he exchanged academic life in Cambridge for a position of higher social distinction in the civil service in London About his work at the Mint, first as warden, then as master, we are well informed by Sir John Craig's authoritative study *Newton at the Mint* (Cambridge University Press, 1946), and the numerous letters and documents now published only serve to confirm and illustrate the already known picture of a conscientious, industrious, efficient, rather harsh and far from progressive administrator

From his last years at Cambridge date Newton's last creative effort in science, his work on the theory of the Moon Other scientific preoccupations, such as the preparation of the second edition of the *Principia*, the publication of the *Opticks*, his taking up the presidency of the Royal Society, have left scarcely any traces in the correspondence Newton's relations with his gifted disciples, Halley and David Gregory, were more concerned with the affairs of the Mint than with problems of mathematics and astronomy In his efforts to work out the numerous corrections to the Moon's orbit, Newton turned to Flamsteed for accurate observational data The cordial spirit in which this collaboration started soon gave way, however, to a painful succession of acrimonious recriminations, which completely spoiled the human relations between the two men

This was the more unfortunate, for they were soon drawn together again in the important and difficult task of publishing the corpus of Flamsteed's very accurate observations and the new star catalogue based on them The lamentable story of this undertaking looms large in the biographies of the two heroes, and its first part is abundantly documented, in the volume under review, by authentic texts of the relevant letters and drafts, for the climax we have still to wait until the next volume appears In a well written preface, the editor, J F Scott, passes a balanced judgment on this painful business, and after perusing the documents I cannot but concur with his plea for looking on Flamsteed's behaviour with more indulgence than on Newton's

This fourth volume of the series is the first to appear under the sole editorship of Dr J F Scott It fully keeps up the standard of excellence of the previous ones Indeed, if anything, it even improves on this standard In particular, it seems that the editor has enlisted a more extensive co-operation of experts on the special topics treated in the letters, thus providing a commentary of the greatest possible accuracy and reliability

L Rosenfeld

DIFFERENTIAL EQUATIONS

Ordinary Differential Equations

A First Course By Fred Brauer and John A Nohel Pp xvi + 457 (New York and Amsterdam W A Benjamin, Inc , 1967) $10 75

Transversal Mappings and Flows

By Ralph Abraham and Joel Robbin Pp x + 161 (New York and Amsterdam W. A Benjamin, Inc , 1967) $12 50

Ordinary Differential Equations is a good textbook for students of applied mathematics, science and engineering The subject matter is not presented as a piece of pure mathematics, with applications, but rather as a series of physical problems leading to differential equations and hence to a need for a theory of such equations, including methods for solution All the usual methods of solution are presented There are chapters on boundary value problems and on systems of differential equations There is no discussion of non-linear equations, but there are chapters on numerical methods of solution and on the use of the Laplace transform in solving equations

Transversal Mappings and Flows is a very advanced and highly specialized book originating in a series of lectures given at the University of Princeton in 1965 It deals with aspects of the qualitative theory of ordinary differential equations, especially the search for generic properties of vector fields Various results are proved by a new method, called transversality theory, which has been developed from basic ideas introduced by Thom in 1954 The first half of the book expounds the foundations of transversality technique and the second half deals with applications to flows

While the book may be of value to researchers interested in the study of dynamical systems, it must be said that it is likely only to be understood by pure mathematicians It starts with a review of the differential calculus in Banach spaces and the theory of manifolds, orientation, vector bundles and other topics belonging to differential topology Various new results or new methods of proof are presented for the first time

PULSE RADIOLYSIS

Pulse Radiolysis of Water and Aqueous Solutions

By A K Pikaev Translated by Scripta Technica, Inc Translation edited by Edwin J Hart English edition revised and augmented by the author Pp xvi + 295 (Bloomington and London Indiana University Press, 1967) 75*s*

Pulse radiolysis is the study of the chemistry of the immediate short lived products of a very short pulse of ionizing radiation, the products usually being detected by their optical absorptions It developed from flash photolysis and has become a rich field of research in the last few years, with the development of the electron linear accelerator and other machines capable of delivering isolated pulses of electrons of many joules of energy and from a few microseconds long down to a few nanoseconds with corresponding rapid rise and fall times This book is the result of a very complete survey of the literature by the author as a way of getting into the field It was originally published in Russian in 1965, but this later English translation has been considerably revised to include as much as possible of the recent publications About half the book deals with the steady state radiolysis of water and aqueous solutions at high and low dose rates This, while not being strictly pulse radiolysis, gives useful background to the many reactions involved and reviews much of the earlier literature The sections on the sources of pulsed radiation and experimental techniques are the weakest part of the book The basic principles behind the experimental techniques are chiefly ignored, particularly the special design of the optical systems needed in this field This is basically a matter of using a very intense light source, getting as much as possible concentrated in the irradiation cell and then getting it down a rather lengthy light path out through a protective radiation maze and eventually through a monochromator on to a photocell The fourth chapter describes the methods for identifying the transient products and determining the reaction rates and, because it is a series of résumés of the recent literature, lacks an overall cohesion A very comprehensive summary of published experiments, however, is contained in two extensive tables Table 15 lists the relative rate constants for the reactions of OH, H and the hydrated electron with more than 200 pairs of solutes, and Table 16 the absolute rate constants for the radicals with more than 500 solutes The book provides a useful introduction to pulse radiolysis and will be a useful reference for those working in the field C W GILBERT

PHYSICAL METHODS IN BIOLOGY

Magnetic Resonance in Biological Systems

Edited by A Ehrenberg, B G Malmström and T Vänngård (Proceedings of the Second International Conference held at the Wenner-Gren Centre, Stockholm, June 1966) (Wenner-Gren Centre International Symposium Series, Vol 9) Pp viii+431 (Oxford, London and New York: Pergamon Press, Ltd , 1967) 140*s* net

A VALID reason for publication of the proceedings of a meeting in book form is to convey the results of ensuing discussions. Unfortunately, in this book any such discussion has been omitted

The forty-nine original research papers presented deal with the applications of highly sophisticated techniques of magnetic resonance, namely. NMR, EPR and Mossbauer spectroscopy, to "sub-molecular" biology, as Hugo Theorell defines it in his opening address There are also introductory papers on electron nuclear double resonance (ENDOR) and nuclear electron double resonance The biological systems range from nucleic acids to paramagnetic metal complexes

It is possible to highlight only a few of the topics covered. NMR is used to gain information about the structure of peptides, to measure fast reaction rates and to determine binding positions in metal complexes EPR is used to probe the structure of heme and non-heme iron proteins, copper-containing enzymes, metal flavoproteins and single crystals of proteins Flow techniques of EPR and their applications to the kinetics of flavin redox systems and to the conformation of labile free radicals are described

The technique of spin-labelling in which a stable organic free radical is attached to a molecule of biological interest and used as a probe is introduced in a paper by McConnell The technique is also applicable to NMR as shown by Sternlicht *et al* Here use is made of the perturbation of a protein spectrum caused by the unpaired spin of the bound radical

The group of papers dealing with Mossbauer spectroscopy is introduced by a paper briefly describing the theory and instrumentation and some applications of the method to ferredoxins In practice the method is limited to molecules containing iron-57

This is a specialist book containing a wealth of information, while the introductory papers are of wider interest The book could, however, have been improved if more papers had contained concise summaries or abstracts

The volume is well produced and contains a good subject index, but the high price reminds one, unfortunately, of the business interest in these publications

BIOLOGICAL CLOCKS

The Physiological Clock

By Erwin Bunning Revised second edition (Heidelberg Science Library) Pp. 167 (London · Longmans, Green and Co , Ltd , New York Springer-Verlag, 1967) 24*s* paperback

WE do some things only or especially at certain times of the day or the year At night, flowers close up, leaves droop, some animals become active, others torpid Marine animals and plants fit their activities to the tides and to the phases of the Moon We have known for some years that most of these rhythmical activities persist for a time when the environmental rhythms are eliminated and it is clearly advantageous to organisms to be able to predict, say, the dawn or the full Moon Some animals navigate by means of the Sun or the stars, some plants and animals regulate their seasonal activities by detecting the length of the night For both these purposes chronometers are needed Professor Bunning's book deals with what we know about the nature of the clock and how organisms use it His examples are drawn from plants, man and other animals His method is to present the problems and then the experiments that bear on their solution, and in many ways the book is a model for what a biological monograph should be An enormous amount of experimental data is presented within a short space, much of it in text figures, and clearly a lot of thought has gone into the arrangement of the work and the elimination of specialist jargon in order to interest all biologists The design of experiments is stressed especially because, in this field, many false conclusions have been reached in the past because of the complexity of an organism's response to its environment

The first edition of the book was published in German in 1958 and a first English edition, based on the second German edition and printed in Germany, appeared in 1964 The second English edition is a revised version of this There are a few more pages, more small print and fewer diagrams Some errors of fact have been corrected This edition retains Professor Bunning's preference for relaxation oscillation as the mechanism of the clock as opposed to harmonic oscillation Arguments on the other side are presented, but half-heartedly Similarly the argument that the circadian rhythm may be a beat phenomenon is dismissed more readily than some of us would like In a monograph by such an authority, such personal preferences are what we want, but I should like it to be more obvious that not everyone agrees

In a book of this excellence it is a pity to have to complain about presentation, but undoubtedly the author does not do himself full justice because of this The book is not easy to read This is due partly to the English style in spite of, or perhaps because of, the battery of experts who have helped the author with the translation It is also partly due to the poor printing There are many spelling and grammatical errors carried over from the old edition and new ones have appeared, although this edition is printed in America The archaic "afore mentioned" [*sic*] has replaced "above mentioned" and words are now often hyphenated at the wrong places

However, all students of biology should make the effort to read the book if they have not already read an earlier edition F A L CLOWES

WATER AND THE WORLD

The Problem of Water

A World Study By Raymond Furon Translated by Paul Barnes Pp xvi + 208 + 14 photographs (London Faber and Faber, Ltd , 1967) 42*s* net

Water, Weather and Prehistory

By Robert Raikes Pp xvi + 208 + 18 plates. (London John Baker, 1967) 45*s* net

THESE books, with a common subject, have very different objectives, but neither author seems to be quite clear what his is or how to reach it

Professor Furon is at the Faculté des Sciences in Paris The sub-title of his book—"A World Study"—seems to promise the kind of synoptic account that would be welcomed by all sorts of hydrologists everywhere, but it contains so much Paris pump hydrology that one wonders why it was translated (Mr Barnes has done a very good job) The author is obsessed with quantities, and his British publishers provide the maddening and quite unnecessary English equivalent for every continental or metric figure quoted As an example that will also reveal the scientific calibre of the book, Furon calculates an annual water use in North America on the basis of the following unsupported statement (page 163) "Each inhabitant in 1960 required daily 2,870 litres (some 650 gall) for industry, 3,210 litres (700 gall) for agriculture, and 500 litres (110 gall) for public supplies" Now all he has to do is multiply by the number of days in the year, then by the population, and out comes an estimate of the 1960 national need (Why bother with measurements when the hydrologists' job can be done as easily as this ?)

The book shows no feeling for qualities, and in spite of a formidable list of references Furon seems to be unaware that there are a few ideas in hydrology, that some of his numbers can be put into a coherent framework, and that there are criteria, not yet all good enough, for rejecting or at least questioning some of the numbers he accepts as established truth As an example he attempts to make out a water balance sheet for part of the Paris basin and, scorning anything as clear as the simple equation of continuity, he gives a long prose account that ends in chaos There is no inquest; yet a telephone call to Versailles could have produced an evaporation estimate (twice the value he used) that would have put things right His own reaction is that it is all very difficult, but it doesn't matter—the area has no economic importance as a source of water

Mr Raikes has the complementary failing of being too much concerned with qualities and not enough with quantities even the quantity that he must use frequently always has a qualitative adjective, monotonously the same (for example, "up the hill in the higher rainfall areas") His philosophy seems to be "I am a civil engineer working on water in and near Baluchistan, if I call my craft 'hydrology' it becomes a science, and I become a scientist—even omniscient As such I can disagree with any professional in any discipline, and by making the reservation (page 28) that this is not intended as a technical treatise, I can dodge the responsibility of reproducing the evidence or reasoning that I question At the end I'll put in a graceful note saying how stimulating these disagreements have been " The result is a book liberally peppered with bright ideas and clever thinking, all praiseworthy even if not all new, but completely spoiled by occasional sneers One of his targets is H H Lamb, ignored by Raikes until on page 101 he is misquoted and his reasoning dismissed as "absurd" On checking Lamb's statement it turns out to be a very cautious inference from someone else's data Absurd ? Not in the least

And now for the books rather than their authors Furon wants the nations of the world to do something about the world's water supply, but it is only in the very last lines that he mentions the International Hydrological Decade, in which more than one hundred governments are doing what he asks for

The book has many short chapters all containing a lot of facts, usually given without a source, not always the same when repeated, and not always converted by the same factor After brief reviews of water in biological material and of the properties of fresh water and sea water, a longer survey of water in agriculture adds very little to what might have been written thirty years ago, but it is here that his own special interest begins to emerge. All too short, there are delightful snippets of information on historical hydro-geology, sometimes irrelevant, but their sparkle emphasizes the dullness of the rest of the book (From one such interlude, Furon concludes that the Syrian climate has not changed in the past 3,000 years, and it is much easier to agree with him than with Raikes making the same assertion) Surveys of water out of control and of water in industry (chiefly French) follow, and then a review of supplies of drinking water comes nearest to being a "world" study After a short chapter on pollution, there is a long account of ways of finding water, with dowsing given an extended discussion that concludes "unbounded credulity is not confined to France" Modern geophysical techniques are described, usually as part of a special case study, but the technical level is low only the easy ideas are explained

The longest chapter is on development problems in arid zones and it seems to be based on an unstated axiom that to grow more food there must be more cultivated land. In the course of examining what the semi-arid regions might contribute he slips into Raikes's theme in considering how far productivity has been affected by climatic change · he concludes that the semi-arid countries round the Mediterranean have the same climate now as 2,500 years ago, but there have been changes in this period (in diary form he tells us that the fifteenth century was a "century of great disturbance caused by astronomical phenomena of intersection of perihelion of Moon with its apsis node during winter solstice"—Mr Raikes, please note) His case studies lead him to the question, "Is further irrigation in the Sahara possible ?" but in effect the answer is on a previous page "The water is worth more than the product" The final chapter—"The Thirst of the World"—contains little more than the figures for North America (already quoted), the decision that we'll not be able to exist on dew but may eventually get our fresh water from the sea

From Sir Mortimer Wheeler's fulsome preface, Mr Raikes's book should be compulsory reading for all students of man's history There are those who attribute the surges in the conflict between nomads and pastoralists to differences in their sensitivity to climatic change, particularly to the shift in extremes that would accompany a shift in a mean Raikes's thesis is that during the past 9,000 years there has been no change in world climate the early cultures that grew near the eastern end of the Mediterranean did so in a climate the same as it is now, and there has been no significant change between. His personal research contribution is based on an acceptable working hypothesis relating kind of culture to rainfall climate and from it he shows that the distribution of archaeological sites corresponds very closely to what would be inferred from present-day isohyets it is a fair deduction that climates now and then are the same This welcome piece of scholarship could be the start of a useful critical discussion, but his arguments about constancy impress neither in form nor in content

Most of the book is about the surface hydrology of semi-arid areas Near the beginning there is an outline of the scope of hydrology, and as one who later makes an earnest appeal for the avoidance of jargon Raikes tucks in a fair amount of his own, here and elsewhere A survey of water and climate as agents in changing geomorphology contains some slightly inaccurate soil physics and some half truths about erosion there is no consideration of any medium other than water for the transport of soil material Two chapters on water as a factor in plant ecology possibly put too much emphasis on the importance of ground-water and the use plants make of it Next comes the partial survey and rejection of the evidence for post-glacial climatic change, and then some interesting case studies show how the special knowledge of a thoughtful water engineer can re-interpret the evidence from archaeological digging. Finally, there is a sermon on the desirability of "The Inter-disciplinary Approach" to large-scale ecological problems, with many words to explain "inter" and none to define "discipline" Although it has all been said before, it needs repetition from time to time, and these two books show that hydrology itself would be a worthwhile subject for treatment H. L PENMAN

LIVING PRIMATES

A Handbook of Living Primates

Morphology, Ecology and Behaviour of Nonhuman Primates By J. R Napier and P H Napier Pp xiv+456 (114 plates). (London Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1967) 126*s* , $21 50

THE study of primate biology as a facet of the analysis of human origins and variation has matured during the past half century, in phase with the development of general evolutionary theory In the late nineteenth century, the standard handbook of the primates—a two volume compendium by H O Forbes, now almost a classic in the field—centred almost exclusively on the natural history (much of it anecdotal) together with the taxonomy of the order. A modern handbook is therefore required to present, in accordance with present systematic practice, not only the much expanded body of morphological data, but also that bearing, for instance, on primate physiology, ecology and genetics It is to this task that Dr and Mrs Napier have addressed themselves in the preparation of this book—the only modern handbook of the primates available today in a concise form

The first section, "Functional Morphology of Primates", presents the major structural features of the order in relation to the presumed overall trends of change discernible through its subdivisions

The second and much the largest part of the work provides a series of abbreviated "profiles" of each primate genus Each profile comprises such data as are available about, for instance, the geographical range, ecology, bodily dimensions, external and internal morphology, locomotion, genetics and serology, behaviour and social life, reproduction and development, together with some notes on longevity and breeding record in captivity Each account is followed by summary lists of references, compounded at the end of the volume into an overall bibliography of some 800 titles

The third section of the work presents a systematic list of the various primate species, correlating, for example, formal and vernacular names, and supplemented by notes relating to the taxonomy of each genus This is followed by accounts, more detailed than would have been appropriate in the second section of the volume, of such topics as the ecology of the African primates, locomotor patterns, limb proportions and associated features, together with such vital statistics of primate genera as have, to date, been gleaned

The volume is illustrated with more than 100 plates of a quality uniformly high and, at times, outstanding

A book of this type must, of necessity, be eclectic and every student of primate biology is likely to note some fact or reference that, in his opinion, ought to have been included or given a different emphasis Others may claim that Dr Napier has possibly given somewhat too great a prominence to certain aspects of primate biology to the detriment of others Again, certain of the general premises outlined in the early pages of the volume are unlikely, in all details, to meet with universal agreement Nevertheless, few will dispute that the present volume provides not only a unique compendium of modern knowledge of primate biology but also a most usable guide to the principal sources of original literature

The volume is intended as a source book, and it would be unjust to reproach the authors for not attempting to enquire into the extent to which contrasts in many of the physiological, genetical and morphological characters correlate or contrast with accepted schemes of primate systematics In many cases, the data are, as yet, insufficient to enable such studies to be carried out effectively and a stated purpose of the work is to indicate the extent of the gaps It is only as these are gradually closed that the overall body of data can be combined in a multivariate scheme summarizing the overall contrasts between extant primate groups ERIC H ASHTON

INDUSTRIAL MICROBIOLOGY

Progress in Industrial Microbiology

Vol 6 Edited by D J D Hockenhull Pp 281. (London. Heywood Books, 1967) 84*s* net

THIS sixth volume of *Progress in Industrial Microbiology* is one of a series of international reviews which each year covers a number of selected topics from the rapidly expanding field of industrial microbiology. This particular volume, edited by D. J D Hockenhull, deals with seven subjects ranging from the production of rifamycins to continuous culture, and should be of interest to workers in many disciplines

As a review it fulfils the function of providing a brief account of the history of most of the subjects, describes the latest developments in research and refers to more detailed works elsewhere

The first paper, "Production of Polyene Antifungal Agents by Streptomycetes", outlines the fungicidal activity and chemical properties of these organisms It also summarizes the toxicities of various polyenes and considers the conditions used in their production This review of Perlman's is particularly useful because the polyene group constitutes a very important group of antifungal antibiotics P. Sensi and J E Thiemann have written a detailed paper on the production of rifamycins—among the latest therapeutic agents Discovered by Sensi, Margalith and Timbal of the Lepetit Research Laboratories in Milan, an important property of rifamycin is that modification of some functional groups of the molecule yields other compounds with high antibacterial activity It seems that the production of rifamycin is favoured by a number of elements and it has also been shown that, for maximum yields of antibiotic, high aeration rates are required only at a very specific stage of the fermentation

The paper which I found most interesting is that on the bacteriology of fish spoilage and preservation by J M Shewan and G Hobbs of the Torry Research Station, Aberdeen As they point out, fish spoilage depends on a number of factors including the initial bacterial flora, the flora acquired during handling and processing, the conditions to which the fish have been subjected during storage and processing, and on the actual chemical composition of the fish Preponderant pathogenic flora are *Pseudomonas, Achromobacter* and *Flavobacterium*, but when fish are caught close to land, typical coliform and food-poisoning bacteria can be isolated Smoking and salting are both traditional methods of preservation, newer methods include freezing, use of antibiotics and irradiation

Other papers in the review are "Studies on the Mechanism of Actinomycin Production", "Recent Developments in the Production and Industrial Applications of Amylolytic Enzymes derived from Filamentous Fungi"; "Large-volume Respirometers with Particular Reference to Waste Treatment", and "Continuous Culture"

The book serves a useful purpose, but, as with all reviews, the material takes time to amass and may therefore be not quite up to date ANNE CLAYTON

BOTULISM

Botulism 1966

Edited by M Ingram and T A Roberts (Proceedings of the Fifth International Symposium on Food Microbiology Moscow, July 1966) Pp xii+531 (London Chapman and Hall, Ltd, 1967) 126*s*

THE fifth international Symposium on Food Microbiology was the first on botulism There are more than fifty papers from at least nine countries in this account of the proceedings

In the first section, on ecology, papers on spore distribution emphasize Russian, American, Scandinavian and English investigations of *Clostridium botulinum* type *E* in fish, mud and soil samples In a paper on fish and fish products associated with type *E* there is some sound commercial and public health advice about the reasonable shelf life of smoked and packed fish products, the action of inhibitors from smoke, and the dangers inherent in casual home or peasant industry production of smoked or preserved fish products

Concerning spore survival there is strong emphasis on certain aspects of food processing, and in particular the association of the concentration of sodium chloride, nitrate and nitrite with the doses of gamma radiation necessary to destroy *Cl botulinum* There is comment on the addition of sodium citrate for this purpose, although further work is clearly needed in this important field of preservation Concerning germination and growth are papers which partly support and substantiate the researches into the action of certain concentrations of sodium chloride, nitrate or nitrite in limiting or preventing growth and toxin production of types *A*, *B* or *E* There is re-emphasis of the inherent dangers of vacuum packed products held at relatively high storage temperatures

The difficulties, as well as the advanced and intensive work, concerning the establishment of precise data about the chemical constitution of botulism toxins are evident from papers in the second section, on the characterization of botulinus toxins Work on the action of some animal and fungal enzymes on toxins has a possible practical application in connexion with the high and low risk of certain foods The action of trypsin on a precursor (protoxin) considered to be practically inactive is investigated in a Japanese paper, which stresses the need for the molecular concept of research Findings from such work may have some clinical significance in the treatment of botulism when the area of maximal toxin absorption in the intestine and the criteria for activation of an inert protoxin are considered

The third section on animal botulism covers the disease in mink, gulls and duck The work on mink is an investigation of type *C* and its toxin production only when mixed with a symbiotic organism Death in gulls caused by botulism is proved, either directly or by drowning when in water, because of loss of stability It seems that a less ill bird may well recover on land but would probably die by drowning when on water

The fourth small section of special topics has a paper which reports how electrophoresis was used to examine relationships between *Cl. botulinum* and non-toxic *Clostridium* or even non-toxic mutants Results are preliminary but encouraging. Other research has suggested that the production of bacteriocine by *Cl botulinum* is not related to its toxigenic power

In the fifth section on laboratory diagnostic methods and techniques there is a specific description of the isolation of type *F* in the Pacific coast area of the United States, and a further paper outlines the problems of isolation and identification from heavily contaminated sources

The final section concerns the control of botulism and clarifies the reasons why controlling this disease needs so much precision and care, and emphasizes the public health problems associated with the difficulties many laboratories have in finding reasonable methods of detecting suspected botulism contamination. A very true reference is made to the generation of management and workers who have never been directly associated with any knowledge of a classical outbreak of botulism This is also praise for the commercial standards in the food industries, but obviously a spirit of apathy or even ignorance could develop Basic knowledge is always needed to appreciate the potential risks and problems. The need to maintain strict standards and not to deviate from proved techniques is substantiated by a description of an outbreak of botulism investigated in North America, involving a canned liver paste

I must congratulate the publishers and the editors, the result of their work is a most comprehensive and informative volume It should be of interest to many workers beyond the immediate field of food microbiology, for so much of the work reported is fundamental rather than applied I L MARTIN

A MODEST PROPOSAL

Report from Iron Mountain

On the Possibility and Desirability of Peace With Introductory Material by Leonard C Lewin Pp 141 (London Macdonald) 18*s*

MR LEWIN's work is almost a major literary event His satire on an American think-tank's treatise on the dire consequences of peace is nearly in a class with Swift's proposal for relieving famine in Ireland The beginning is brilliant John Doe, a professor at a large university in the Middle West, "telephoned me one evening last winter. . We met for lunch the next day at a midtown restaurant He was obviously disturbed . ".

The suspense grows What Mr Doe has to hand over is the report of a Special Study Group organized by the American government to prepare a contingency plan for "permanent peace" The group's first and last meetings were held at Iron Mountain, New York (a real place where corporation records are stored on microfilm in underground vaults), but otherwise it shifted from place to place to preserve secrecy Its conclusions were so shocking—that war is necessary to social stability—that both the committee and the government suppressed it. Mr Doe (a pseudonym, of course) none the less felt obliged to see the report published and handed it over to Mr Lewin, who saw to publication

The book is said to have caused great stir in America, where some people think that Professor Galbraith is the true author and others even suspect that it is the genuine handiwork of a secret governmental commission That is hard to believe The body of the book—the alleged "report"—displays the same wit and style as does the introduction, the best guess is that it is Mr Lewin's handiwork through and through His ear for the speech of the American defence pedant is perfect that blend of ponderous jargon and uncomfortable frankness: "Most of us [the committee] and that includes me, had a record of abnormally high uric acid concentrations in the blood" The trouble is that his imitation succeeds too well. The report, as it is spun out, is as dull as its real-life counterpart page-length paragraphs, cluttered with italics and footnotes and latinate neologisms

The question to be asked is whether this book is genuinely shocking People who believe in general and complete disarmament will think so and will be grateful to Mr Lewin for exposing the callousness of some American strategists What could be uglier than to calculate that war is necessary, not only as a balance to an economy otherwise regulated by supply and demand, but as a siphon to remove the ignorant young disruptive men from society ? But whether others will find it disturbing is doubtful Is war really "the principal motivational force for the development of science at every level" ? If one cannot assent to this, or similar assertions, then the thesis of Iron Mountain Boys (as they sometimes referred to themselves) loses its force

It is even possible that this book fails in its purpose to stimulate people to think about the dependence of the American economy on weapons production and of the American government on the advice of experts who suppose themselves to be objective It pretends that there is no permanent peace because societies do not find it useful, rather than because aggression is part of the human condition And it perpetuates the "we-they" myth that is what wars are often about "We" are quite different from "them" and they are wrong ("Them" in the context of this book are the think-tanks, the Rand Corporation, the Hudson Institute, and Mr Herman Kahn, the father of the mega corpse)

A modest proposal, therefore, from an admirer Mr Lewin is an excellent writer his dialogue is crisp, his mastery of the idiom faultless, his sense of showmanship superb, and could anyone have thought of a better title ? Could he not acknowledge his authorship of this book and go on to writing more fiction ? BRENDA MADDOX

University News : University College of Swansea

DR P C THONEMANN, at present chief research scientist, Division head, Experimental Division B, Culham Laboratory, UKAEA, has been appointed a professor of physics and head of the Department of Physics as from April 22

Appointments

REAR ADMIRAL JOHN E. CLARK has been appointed deputy director of the Jet Propulsion Laboratory of the California Institute of Technology

DR S G OWEN, at present reader in medicine and clinical sub-dean in the University of Newcastle upon Tyne, has been appointed second secretary to the Medical Research Council

Announcements

THE Institution of Chemical Engineers has instituted a new medal, the Council Medal, which is to be awarded annually to a person who has given exceptional service to the institution on a special project or projects The first award is to be made to Mr P L Baldwin, in particular for his work as chairman of the working party on "The Controlled Storage and Recovery of Particulate Solids" The Arnold Greene Medal, given annually for contributions to the institution's progress, has been awarded to Mr H Fossett

Meetings

ELECTROCHEMISTRY, February 19–23, Melbourne (Dr D F A Koch, Division of Mineral Chemistry, CSIRO, P O. Box 124, Port Melbourne, Victoria, Australia)

CITRUS Symposium, March 17–26, University of California, Riverside (Professor H D Chapman, Department of Soils and Plant Nutrition, University of California, Riverside, California 92502)

METALLURGICAL Developments in Low-Alloy Steels for Mechanical Engineering Applications, April 2–4, Scarborough (Mr J R Powell, BISRA, 24 Buckingham Gate, London SW1)

HIGH Pressure Research Meeting, April 9–11, Centre d'Etudes Nucléaires de Cadarache (M Rapin, CEA, Service MA, B P 61, 92 Montrouge, France)

INTERFERENCE Problems associated with the Operation of Microwave Communications Systems, April 22–24, Institution of Electrical Engineers (Conference Department, The Institution of Electrical Engineers, Savoy Place, London WC2)

AUTOMATION for Productivity, May 14–16, Institution of Electrical Engineers (Conference Department, The Institution of Electrical Engineers, Savoy Place, London WC2)

INDUSTRIAL Measurement Techniques for On-line Computers, June 10–14, Institution of Electrical Engineers (Conference Department, The Institution of Electrical Engineers, Savoy Place, London WC2)

CORRESPONDENCE

SI Units

SIR,—The issue of *Nature* of December 30 (216, 1272, 1967) quotes a draft of a document by a committee of the Royal Society on metric units and the SI Listed together with SI units are "Units to be allowed in conjunction with SI" These are described in the text as "compatible" with SI although the meaning of this is not clear in many cases it appears to be merely that they are multiples of ten times the SI unit These multiples are not, in general, in the recommended steps of one thousand

The SI at last offers a real opportunity of establishing a coherent system of units which is common to both scientists and engineers Once alternative units are allowed, coherence is lost and we will continue to have "working formulae" (using the non-SI units) which differ from the basic equations Conversion factors, the curse of applied scientists, will remain with us—and they will be unfamiliar ones It is difficult to understand why a body such as the Royal Society should advocate the retention of non-SI units such as the poise and stoke—presumably merely because they are familiar The case for the bar is little better it is of convenient size for some purposes, but is this of any real consequence ? The use of prefixes to indicate multiples and submultiples of basic units is an entirely satisfactory and well established practice for example, the μF and pF are in everyday practical use, the basic unit, the farad, being itself well outside the range of magnitude commonly encountered The SI unit of pressure, the N/m^2, is not far from the centre of the range of common pressure measurement, bearing in mind the existence of vacuum technology.

Is it too late to hope that the Royal Society will fully recognize the advantages of having one unit for one quantity, and of having coherent units, and therefore to abandon the bar, stoke, poise and gauss ? No doubt there is justification for a few non-SI units, but it does not exist for these quantities

G W. ALDERTON

39 Cross Green,
Upton Heath,
Chester

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, February 5

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, WC2), at 5 30 p m —Mr F E Williams, Mr F A Wilson and Mr K A T. Knox "Future Trends in the Design of Subscribers' Telephone Instruments"

Institution of Electrical Engineers, Joint Professional Group (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Specification of the British Electrical Indicating Instrument", opened by Mr L B S Golds

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 6 p m —Mr L G Culleton Presidential Address

Society of Chemical Industry, London Section (joint meeting with the Fine Chemicals Group, at 14 Belgrave Square, London, SW1), at 6 30 p m —Professor R C Cookson "Some Aspects of Photochemistry"

Tuesday, February 6

Society of Chemical Industry, Pesticides Group—Physicochemical and Biophysical Panel (at 14 Belgrave Square, London, SW1), at 10 a m —Symposium on "The Effects of Rain on Plants and Pests"

University of London (at the Royal Veterinary College, Royal College Street, London, NW1), at 5 p m —Professor M G P Stoker "Tumour Viruses and Tumour Cells" *

Chelsea College of Science and Technology, University of London (at College Hall, College House, Manresa Road, London, SW3), at 5 30 p m —Professor Dorothy Hodgkin, OM, FRS "Molecules and Biology" (Chelsea Lecture)

Institution of Electrical Engineers, Control and Automation Division (at Savoy Place, London, WC2), at 5 30 p m —Mr K Smith "Automatic Landing of Aircraft—Control Techniques in All-weather Aircraft Operations"

Institution of Electrical Engineers, Power Division (at Savoy Place, London, WC2), at 5 30 p m —Mr K R Haigh "Electrical Cable Glands for Underwater Vehicles and Oceanographic Equipment"

Royal Institution (at 21 Albemarle Street, London, W1), at 5 30 p m —Sir Lawrence Bragg, CH, FRS "How We Hear, Speak and See" (McRobert Lecture Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties To be repeated on February 7)

University of London (at King's College, Strand, London, WC2), at 5 30 p m —Dr M. H Seevers (Michigan) "Psychological Aspects of Drug Dependence" *

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Professor A N Davison "The Myelin Sheath and Its Biochemistry" (Eighth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Society of Chemical Industry (at 14 Belgrave Square, London, SW1), at 6 p m —Dr N J L Megson "Leo Hendrik Baekeland and the Chemistry of Phenolic Resins" (Baekeland Memorial Lecture)

Wednesday, February 7

Colour Group (Great Britain) (at Imperial College, London, SW7)—Meeting on "Cosmetics" Dr T J Elliott "Colour Cosmetics", "Television Make-up" by a member of the BBC Make-Up Department

Royal Institution, History of Science Discussion Group (at 21, Albemarle Street London W1), at 1 p m —Lt Commander D W Waters "The Adoption of Marine Time Keepers at Sea" *

Society for Analytical Chemistry (at the Wellcome Foundation, Euston Road, London, NW1), at 3 p m —Meeting on "Enthalpimetry"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, WC2), at 5 30 p m —Dr H G Lubszynski, Mr N Barford, Dr B Mayo and Mr J Wardley "A New Electrostatically Focused and Deflected Vidicon", Mr P C Ruggles, Dr N A Slark, Mr D P Mouser and Mr P H Batev "Beam Separation and Low Noise Read-out in Isocons"

Royal Microscopical Society (at the Middlesex Hospital Medical School, Cleveland Street, London, W1), at 5 30 p m —Dr A Boyde "Electron Microscopy of Surfaces of Hard and Soft Tissues"

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Professor J G Robson "Pain and Pain Suppression" (First of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation)*

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Training of Engineers for Management"

University of London (at the Institute of Archaeology, Gordon Square, London, WC1), at 6 p m —Mr I P Joliffe "Sources of Maritime Archaeology —Coastal Research in Britain" *

Thursday, February 8

Royal Society (at 6 Carlton House Terrace, London, SW1), at 9 30 a m —Discussion Meeting on "The Logical Analysis of Cerebral Functions" organized by Professor J Z Young, FRS, and Professor H C Longuet-Higgins, FRS

Royal Institution, Library Circle (at 21 Albemarle Street London, W1), at 1 p m —Mr E Howe "William Savage and the Royal Institution"

Society for Analytical Chemistry, Particle Size Analysis Group and the North of England Section of the Society for Analytical Chemistry, with the Manchester Section and Colloid and Surface Chemistry Group of the Society of Chemical Industry (at the Manchester Literary and Philosophical Society, 36 George Street, Manchester), at 2 30 p m —Meeting on "Dispersion Problems in Particle Size Analysis"

Institution of Electrical Engineers, Control and Automation Division (at Savoy Place, London, WC2) at 5 30 p m —Mr R H D Hardy "A System for Transmission and Display of Weather Information"

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Dr A M Harper "Regulation of Cerebral Circulation" (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Institution of Mechanical Engineers, Internal Combustion Engines Group, and the Diesel Engineers and Users Association (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Investigation of Diesel Engine and Turbo-Charger Interaction"

University of London (at Queen Elizabeth College, Campden Hill Road, London, W8), at 6 p m —Professor D Gabor FRS "Foreseeing and Controlling the Future" *

Arboricultural Association (in the Lecture Room Royal Horticultural Society's New Hall, Greycoat Street, London, SW1), at 6 30 p m —Mr Roland Huddleston and Mr Michael Hardy "The First Six Months of the Civic Amenities Act"

University of London (at Withersdane Hall, Wye College, near Ashford, Kent), at 8 15 p m —Professor J N Black "Energy Relations in the Management of Resource Systems" *

Friday, February 9

Federation of British Plant Pathologists (in the Lecture Theatre, British Museum (Natural History), Cromwell Road, London, SW7), at 10 50 a m —Discussion Meeting on "The Techniques and Problems in the Production and Use of Virus-tested Planting Material"

Royal Institution Photochemistry Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Dr Y V Morozov "Radiative and Radiationless Transition Probabilities in Organic Molecules" *

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, WC2), at 5 30 p m —Mr G F Craven "Evanescent Mode Filters"

Royal Institution (at 21 Albemarle Street, London, W1) at 9 p m —Professor Paul T Matthews, FRS, "Elementary Particles".

Saturday, February 10

British Society of Rheology, and the British Microcirculation Society (at the Royal College of Surgeons, Lincoln's Inn Fields, London, WC2)—Symposium on "Haemorheology and the Microcirculation"

Inner London Education Authority (at the Horniman Museum London Road, Forest Hill, London, SE23), at 3 30 p m —Professor A N Tucker "Life and Death of an East African Rainmaker" *

Monday, February 12

University of London (in the Botany Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Dr R J Benthem (Utrecht) "Conservation in Land Use Development I Reconstruction of Landscape" *

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Passenger Handling"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer (with a good honours degree in mechanical engineering or in a related subject, and preferably a particular interest in mechanical vibration and/or control systems) in the Mechanics and Mechanism Group of the Department of Mechanical Engineering, to contribute to the teaching and research work of the Department in the field of dynamics—The Secretary to the University Court, The University, Glasgow (February 10)

Lecturer or Assistant Lecturer (preferably with research interests in semi-conductors, solid state electronics and surface electronics) in the Department of Electrical Engineering and Electronics—The Registrar, The University, Liverpool, quoting Ref RV/342 (February 15)

Assistant Lecturers or Lecturers (2) in the Department of Pure Mathematics (for at least one of these posts preference will be given to applicants with special interest in functional analysis)—The Registrar, The University, Liverpool, quoting Ref RV/313 (February 16)

Lecturer (either medically or scientifically qualified candidate) in the Department of Chemical Pathology—The Registrar and Secretary, The University, Leeds, 2 (February 17)

Lecturer (with a higher qualification in medicine) in Therapeutics—The Acting Secretary, The University, Aberdeen (February 17)

Lecturers (2) (with university, commercial or industrial experience in some branch of computer science) in Computing—The Secretary, The University, Aberdeen (February 17)

Second Chair of Applied Mathematics—The Registrar, The University, Newcastle upon Tyne (February 17)

Research Fellow in Textile Engineering to investigate problems concerned with the division of heat and wear between two high speed steel rubbing surfaces—The Registrar and Secretary, The University, Leeds, 2, quoting Ref 68/38/2 (February 19)

Assistant Lecturer in Biometrics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (February 20)

Lecturer (with a good honours degree and preferably a minimum of two years' practical experience in industry and/or research) in the Department of Civil Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E1 (February 23)

Assistant Experimental Officer (with a degree in a biological subject or an equivalent qualification) to take part in research on hybrid varieties of wheat and barley—The Secretary, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge (February 26)

Lecturer or Assistant Lecturer in Experimental Psychology—The Assistant Registrar (Establishment), The University of Sussex, Essex House, Falmer, Brighton, Sussex, quoting Ref 873/1 (February 29)

READER IN ANTHROPOLOGY at the LONDON SCHOOL OF ECONOMICS—The Academic Registrar (A), University of London, Senate House, London, WC1 (March 1)

READER/SENIOR LECTURER in MATHEMATICS (STOCHASTIC PROCESSES) at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Brisbane, March 1)

SENIOR LECTURER, LECTURER or ASSISTANT LECTURER (preferably with a special interest in comparative vertebrate zoology or animal physiology or animal (vertebrate) ecology) in ZOOLOGY at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, WC1 (March 8)

UNIVERSITY POSTDOCTORAL TEACHING FELLOW in the DEPARTMENT OF CHEMISTRY—The Registrar, University of Nottingham, University Park, Nottingham NG7 2RD (March 29)

CHAIR OF PHYSICS, and CHAIR OF CHEMISTRY at Flinders University of South Australia—The Registrar, Flinders University of South Australia, Bedford Park, South Australia, or The Secretary-General, The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia, March 31)

GWENDOLYN MICHELL CHAIR OF MEDICINE at the University of Adelaide—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia, March 31)

CHAIR OF PHYSICS—The Institute of Physics, University of Aarhus, 8,000 Aarhus, C, Denmark (April 1)

MASTER (preferably with an interest in statistics or computer work) to teach Mathematics to all levels including the Sixth Form—The Master, Dulwich College, London, SE21

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14.0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A (by air freight)*	*Canada*	*Elsewhere (surface mail)*
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13 10 0**
6–11	**£12 15 0**	**$44 50**	**$48 30**	**£12 15 0**
12 or more	**£12 0 0**	**$42 50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A)

Isotopes in Chemistry

J. F. DUNCAN *and* G. B. COOK

The text is not confined to simple tracer studies, but includes topics arising directly from the properties of the isotopes themselves—isotope effects, recoil, electronic and nuclear excitation, and the artificial elements—and relates them to other fields (e g stable isotopes, nuclear magnetic resonance, and the Mossbauer effect) Readers will obtain a general view of the versatility of isotopic methods, which are still breaking into new fields of study 71 *text figures* 55*s net* (*paper covers* 27*s* 6*d net*)

Chemistry and Industry

Applications of Basic Principles in Research and Process Development

Edited by D G. JONES

This book aims to give students an idea of the way in which basic concepts are applied across the whole field of industrial research and development There are chapters dealing with examples of such applications in physical, organic, and inorganic chemistry and in the development of a chemical process 58 *text figures* 40*s net* (*paper covers* 20*s net*)

Theory of Crystal Dislocations

F. R. N. NABARRO

A comprehensive survey of our present knowledge of the theory of dislocations in crystals Attention is paid not only to the geometrical and elastic properties of dislocations in a continuum and in a crystal, and to the interactions of dislocations with point defects, but also to the effects of dislocations on the electrical, magnetic, thermal, and optical properties of crystals 231 *text figures* £9 9*s net* *International Series of Monographs on Physics*

BIOCHIMICA ET BIOPHYSICA ACTA

PROTEIN STRUCTURE

ELSEVIER'S JOURNAL FOR PAPERS AT THE FOREFRONT OF RESEARCH ON PROTEIN FINE STRUCTURE AND CONFORMATION

Isolation and covalent structure - solution properties - subunit dissociation and interaction - immunochemistry - probing of active sites - magnetic and spectroscopic analysis of metallo- and pigment-bearing proteins - electron microscopy of proteins

A sample of forthcoming papers

Amino acid composition of β-lactoglobulins - K. Bell, H.A. McKenzie & D C. Shaw (Canberra, Australia)
Structural characterization of hemoglobin N_{Seattle} R.T Jones *et al* (Portland, USA)
Trennung der *S*-Sulfonate des Schweineinsulins an DEAE-Sephadex Y. Shimonishi & H Zahn (Aachen, Germany)
Naturally occurring analogues of porcine corticotropin S Lande *et al* (New Haven, USA)
Albumin volume and conformational change relationships S Katz (Morgantown, USA)
Fibrinogen - fibrin interaction V.A. Belitser *et al* (Kiev, USSR)
Rheumatoid factor-reactive peptides from human IgG C.S Henney, R Jefferis & D R Stanworth (Birmingham, UK)
Myosin B from Myxomycete plasmodium S Hatano & M. Tazawa (Nagoya, Japan)
Energy transfer in oligotyrosyl compounds - J.A. Knopp & J W. Longworth (Oak Ridge, USA)
Circular dichroism of squid rhodopsin Y. Kito, M Azuma & Y Maeda (Osaka, Japan)
Etude du spectre infra-rouge du collagène acido-soluble A Huc & J Sanejouand (Lyon, France)
Optical and magnetic properties of Pseudomonas azurins A.S Brill, G.F. Bryce & H J. Maria (New Haven, USA)

Ordered as a part subscription to BBA, a personal or departmental 'Protein Structure' costs US$54.00

Details for 1968·
Biochim Biophys Acta, Vols.154, 160 & 168 (P4, P5 & P6), 9 issues, total price US$54.00, Dfl.195.00. Airmail surcharge for USA and Canada US$0 90

Back volumes P1, P2 & P3 (1967) are also available

APPOINTMENTS VACANT

DEPARTMENT OF PHYSICS
UNIVERSITY OF WINDSOR
WINDSOR, ONTARIO, CANADA

Applications are invited for the following staff appointments

1. EXPERIMENTAL PHYSICIST (Atomic Physics) Preference will be given to candidates with interests in atomic collision optical pumping or similar phenomena
2. EXPERIMENTAL PHYSICIST (Solid State Physics) Preference will be given to candidates with interests in E S R, optical properties of solids and related subjects
3. THEORETICAL PHYSICIST Preference will be given to candidates with interests in the physics of atomic collisions

In each case the successful candidates will be expected to instruct in undergraduate and postgraduate courses and to devote a part of their time to research The appointments may be made at the ranks of Assistant Professor, Associate Professor or Professor at which properly qualified candidates can expect salaries of not less than $9 000 $12 000 and $15 000 per annum respectively

Inquiries should be addressed to Dr L Krause, Head Department of Physics (393)

TWYFORD LABORATORIES LIMITED

(A subsidiary of Arthur Guinness Son and Co (Park Royal) Ltd

require

LABORATORY TECHNICIAN

to join a small team working on biological and chemical problems associated with bacterial endotoxin As the work will be concerned with the chemical aspects of the research, an interest in chemical analysis is essential, and experience in this type of work would be helpful

The person we select is likely to have some 'A' levels (including chemistry), or O N C or similar qualifications

The conditions of employment are good, and include free lunches, generous pension, life insurance schemes and sickness benefits, 16 days' annual leave Salary will be on scale from £850 to £1 250 according to age and experience

Apply to the
Personnel Officer,
TWYFORD LABORATORIES LTD
309 Elveden Road,
N W 10

(431)

UNIVERSITY OF WATERLOO
DEPARTMENT OF BIOLOGY
WATERLOO, ONTARIO, CANADA

Applications are invited from students for postgraduate studies leading to M Sc or Ph D Areas of research cover most fields of biology including Freshwater Biology, Taxonomy Microbiology, Physiology, Genetics and Palynology Teaching Fellowships to the value of $2,600 for eight-month academic year, plus summer stipend of $1 000 available Dr H B N Hynes, Chairman

Applications to be addressed to Department of Biology, University of Waterloo, Waterloo Ontario Canada (405)

Analytical Microscopist

The output of our client's modern, well-equipped, clean, air-conditioned laboratories, situated North-west of London, is visible proof that they have one of the most advanced instrument development facilities in Europe

A replacement is now required for their microscope specialist who has been promoted to head the Assessment Department Supported by existing physical and chemical services, the position would suit applicants with experience in the use of modern polarising and UV microscopes in forensic, organic, physical, biomedical or petrological analysis and possessing a degree or equivalent in an appropriate subject The appointee will be contributing to the improvement of sensitive instrument systems, whose performance is strongly influenced by recondite aspects of physical chemistry, using an elaborately equipped Zeiss Photomicroscope for assessment and isolation of unidentified materials, of organic contaminants and their properties, and to support research into the surface processes concerned

If you are interested in discussing this appointment, which offers work on problems in new and unexplored fields, besides generous conditions of service such as four weeks holiday a year and assistance with housing, please write, giving a brief summary of your career to date, to

T. L Roberts (Ref. AM/218),
R F. White & Son Ltd.,
(Incorporated Practitioners in Advertising)
72 Fleet Street,
London, E.C 4.

(Should there be a company to whom you do not wish your application to be forwarded please advise by covering letter)

(492)

Agricultural Science Graduate

required by **AN FORAS TALUNTAIS (The Agricultural Institute)** for its Soil Fertility/Chemistry Department Starting salary up to £2,465 depending on qualifications and experience Marriage and children's allowances Superannuation Scheme (special arrangements can be made in the case of an F S S U member) ESSENTIAL Honours University Degree or equivalent

Further particulars and application forms from the Director, An Foras Taluntais, 33 Merrion Road, Dublin, 4, Ireland (Quote ref N3) Latest date for receipt of completed forms—February 28, 1968

(414)

RESEARCH ASSISTANTSHIPS IN PHYSIOLOGY

Applications are invited for Research Assistantships from qualified students wishing to work towards the M Sc or Ph D degrees Stipend range $3 000 to $3 600 per annum

Write for further information to

Dr D H Copp Head,
Department of Physiology,
University of British Columbia
Vancouver 8, B C, Canada (401)

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTS

Pedology Department has vacancies for (A) CHEMIST to work on soil organic matter/trace elements (B) CHEMIST/PHYSICIST to study soil minerals by X-ray diffraction Applicants should have H N C, L R I C, or B Sc degree Salary according to age and experience in grade of Assistant Experimental Officer (£744 to £1 243) or Experimental Officer (£1,365 to £1 734) Superannuation

Applications to the Secretary, giving full particulars and names of two referees and quoting reference 1052/105 A or B, to the Secretary by February 29, 1968 (399)

HUNTINGDON RESEARCH CENTRE

RESEARCH OFFICERS

Graduates in biological sciences are required for participation in research work in the field of safety evaluation of drugs and other chemicals Preference will be given to candidates under 25 years of age who have an interest in mammalian systems, associated with a broader physicochemical knowledge They should have initiative and organising ability, and experience in some facet of the pharmaceutical industry would be considered an advantage Library and social facilities are good, and four weeks' holiday will be granted per year

Applications should be addressed to the Personnel Officer, Huntingdon Research Centre, Huntingdon, quoting reference GHW/5/G (483)

UNIVERSITY OF GLASGOW

CHAIR OF VETERINARY PATHOLOGY

Applications are invited for appointment to the Chair of Veterinary Pathology which will become vacant on October 1, 1968, by the retirement of Professor J W Emslie The holder of the Chair has responsibility for the subjects of Veterinary Pathology, Bacteriology and Parasitology

Applications (twenty copies), with the names of three persons to whom reference may be made should be submitted not later than February 29, 1968 with the undersigned, from whom further particulars may be obtained

ROBT T HUTCHESON,
Secretary of the University Court
(439)

FOURAH BAY COLLEGE

UNIVERSITY OF SIERRA LEONE

Applications invited for (a) Lectureship or (b) Assistant Lectureship in Geology Candidates preferably with postgraduate experience, should have interests in the field of metamorphic petrology Salary (a) Leone 2,400 to Leone 4 740 per annum , (b) Leone 1,900 to Leone 2,400 per annum F S S U (1 Leone=10s sterling), plus supplementation (normally tax free) of £275 to £350 per annum (sterling) for those designated under British Expatriate Supplementation Scheme Various allowances , family passages

Detailed applications (six copies), naming three referees by March 14, 1968, to Inter-University Council, 33 Bedford Place, London, W C 1, from whom particulars are obtainable (489)

UNIVERSITY OF BOTSWANA, LESOTHO AND SWAZILAND

Applications invited for (a) Lectureship or (b) Assistant Lectureship in Crop Production for duties in Swaziland at the Agricultural College and University Centre Applicants should have a degree in Agriculture or Tropical Agriculture plus graduate experience in the Tropics or Sub-Tropics Experience in the field of Agricultural Education advantageous Duties to be assumed July, 1968, or soonest thereafter Salary (a) R 3 100 to R 4,700 per annum , (b) R 2,600 to R 2,800 (1 Rand=11s 8d sterling) Various allowances , gratuity , family passages , biennial overseas leave

Detailed applications (six copies), naming three referees by March 20, 1968, to Inter-University Council, 33 Bedford Place, London, W C 1 from whom particulars are obtainable (488)

UNIVERSITY COLLEGE OF NORTH WALES

ASSISTANT LECTURER IN BIOMETRICS

Applications are invited for the post of Assistant Lecturer in Biometrics The person appointed will be responsible for teaching and some consultation in the application of statistics to biological problems He may also lecture on mathematics at an elementary level to first-year biology students The person appointed would be a member of the staff of the School of Plant Biology The salary will be at a suitable point on the scale £1,105 by £75 to £1,180 by £80 to £1 340

Applications (two copies), giving details of age, qualifications and experience, together with the names of three referees, should be sent by February 20 1968, to the Secretary and Registrar, from whom further particulars may be obtained (420)

Senior Research Physical Metallurgist–

AUSTRALIA

An important overseas Group company, John Lysaght (Australia) Limited, which makes and markets sheet steel and a range of processed and fabricated products, with an annual turnover well into eight figures (sterling), wishes to appoint a Ph D in metal physics or physical metallurgy to its Central Research Laboratory staff at Newcastle, New South Wales. Candidates should have had several years of research experience since obtaining their higher academic qualifications

Participation in the company's research programme will be both challenging and rewarding The present programme includes orientations in various types of low carbon steels from hot coil to finished product, via control of recovery and recrystallisation processes, following interstitial elements by Mossbauer, electron microscopy, X-ray diffraction

Commencing salary will be negotiated around $A7000 Excellent superannuation scheme, free life assurance and other staff benefits Fares and transport will be arranged and some assistance will be given with getting suitable accommodation in Australia

A MEMBER OF THE GKN GROUP OF COMPANIES

Please write, in strict confidence, quoting U 108, to the
Director of Personnel,
Guest, Keen & Nettlefolds Ltd.,
22 Kingsway, London, W.C 2

(510)

Plastics Division

ICI

We have vacancies for

ABSTRACTORS

in the Patents and Library Department at our Welwyn Garden City Headquarters Desirable qualifications are 1(a) a degree or Higher National Certificate (Chemistry) or (b) the completion of Part I or the whole of a degree course in Chemistry, irrespective of the result and (2) a working knowledge of a foreign language The work comprises abstracting, indexing and searching the patent and academic and technological literature on the production and use of plastics materials

Conditions of service include a 37½-hour, five-day week, Pension Fund and Profit Sharing Scheme Recreation and Restaurant facilities are available

Apply briefly quoting ref No A23220 to
P. J. Whittingham, Personnel Department,
Imperial Chemical Industries Ltd.,
PLASTICS DIVISION,
Bessemer Road, Welwyn Garden City, Herts.
(432)

THE QUEEN'S AWARD TO INDUSTRY

Glaxo Research Ltd.
Stoke Poges, Bucks.

Fermentation Research

Our extended research programme gives rise to the following senior appointments

Biochemist

is needed to take charge of one of a number of research projects in the Biochemistry Section He should be interested in working with biological products from micro-organisms and preferably should have had experience in the fields of nucleic acid and/or enzymes He would be supported by graduate and technical assistants.

The position would be suitable for a Ph D. biochemist with at least 2 years' post-graduate practical experience Ref. U 260

Biologists

There are two vacancies for mature graduates to work on the discovery of new microbial metabolites in the fields of enzymes and antibiotics Candidates should combine a sound knowledge of microbiology and genetics They should have a Ph D or alternatively be graduates with considerable research experience They will have appropriate technical assistance Ref U 261

Auto-Analyst

to run an expanding section where the work is concerned with the analysis of metabolites and where there is scope for the development of new assay methods Computer facilities are available for data analysis Candidates should be graduate chemists or the equivalent with a comprehensive training in chemical analysis and also experience in auto-analytical techniques Ref U 262

We pay progressive salaries and offer excellent working conditions and fringe benefits including pension and bonus schemes Please write quoting the appropriate reference to the Senior Personnel Officer (GJB), Glaxo Laboratories Ltd, Greenford, Middlesex

(509)

UNIVERSITY OF EDINBURGH

Department of Pharmacology

GRADUATE BIOCHEMIST required to assist in a research programme on the metabolism of cerebral tissues Research experience in separative biochemical methods desirable, but not essential Opportunities exist for study for a higher degree Salary Scale £1,050 to £1,340 per annum

Applications, in writing to the Clerical Officer, Unit for Brain Metabolism, Department of Pharmacology, University Medical School, Teviot Place, Edinburgh 8 (456)

BROOKE BOND RESEARCH LABORATORIES

BLOUNTS COURT,
SONNING COMMON, READING,
BERKS

A SCIENTIST or TECHNICIAN is required for Taste and Odour evaluation work in connection with tea and other consumable products Salary will be commensurate with age and experience

Applications to the Administrative Office at the above address, quoting reference SE

(435)

POSTGRADUATE STUDY IN CHEMISTRY

UNIVERSITY OF MANITOBA

Financial support up to $4,200 per annum for First and upper Second-class honours graduates in M Sc and Ph D programmes in chemistry Travel assistance available

Details from R H Betts, Head Chemistry Department, University of Manitoba, Winnipeg 19, Manitoba, Canada (236)

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF APPLIED MATHEMATICS

Applications are invited for a post of LECTURER or ASSISTANT LECTURER in Applied Mathematics The current research interests within the department lie primarily in the fields of Fluid Dynamics Numerical Analysis and Plasma Dynamics but applications for this post may be made by candidates with interests in any branch of Applied Mathematics Salary scales Lecturer £1 470 to £2 630, Assistant Lecturer £1 105 to £1 340, starting salary according to qualifications and experience F S S U, grant towards expenses of furniture removal

Five copies of applications with the names of three referees should be lodged by February 29 1968 with the Secretary of the University College Gate, St Andrews from whom further particulars may be obtained (485)

EAST MALLING RESEARCH STATION

STATISTICS SECTION

Vacancy for an able graduate in Statistics or Mathematics Research encouraged Biological or horticultural interests an asset Access to computers Appointment in the Scientific Officer grade or possibly Senior Scientific Officer subject to adequate prior experience

Further details and application forms from the Secretary, East Malling Research Station, Maidstone, Kent (426)

MEDICAL RESEARCH COUNCIL

BIOLOGICAL STANDARDS

The National Institute for Medical Research has a vacancy in the Division of Biological Standards for an honours graduate, preferably trained in chemistry, to work on development and application of the radioimmunoassay technique to measurement and study of various biologically important polypeptides Incremental salary, within the range £1 050 to £1,785 per annum, according to age and qualifications, with F S S U benefits

Applications should be sent, by February 29, 1968 to the Director, National Institute for Medical Research, Mill Hill, London, N W 7 from whom further particulars may be obtained (467)

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON)

Applications are invited for the post of Research Assistant in the Department of Crystallography for a team engaged on research on the X-ray structure determination of crystalline proteins. Applicants should possess qualifications or experience in scientific programming and preferably some acquaintance with crystallography Salary on the scale of £890 by £55 to £1,110 by £75 to £1,260 per annum

Application forms may be obtained from the Secretary, Birkbeck College, Malet Street W C 1 Closing date February 19, 1968 (428)

MANCHESTER REGIONAL HOSPITAL BOARD have a vacancy for a male or female Scientific Officer in the laboratories of the BLOOD TRANSFUSION SERVICE An Honours degree in science pharmacy or biology is essential Salary £963 (first- or second-class honours) rising to £1,658, though candidates with postgraduate qualifications or experience may be given a higher starting salary—Applications should be sent to the Director, Regional Blood Transfusion Centre, Roby Street, Manchester from whom further particulars may be obtained (429)

BIOCHEMIST REQUIRED TO ASSIST IN research on bile pigment metabolism Experience with liver perfusion techniques and enzymes desirable but not essential Opportunities for higher degree Salary £930 to £1 400—Further details from Dr B H Billing, Medical Unit Royal Free Hospital Gray's Inn Road, London W C 1 (390)

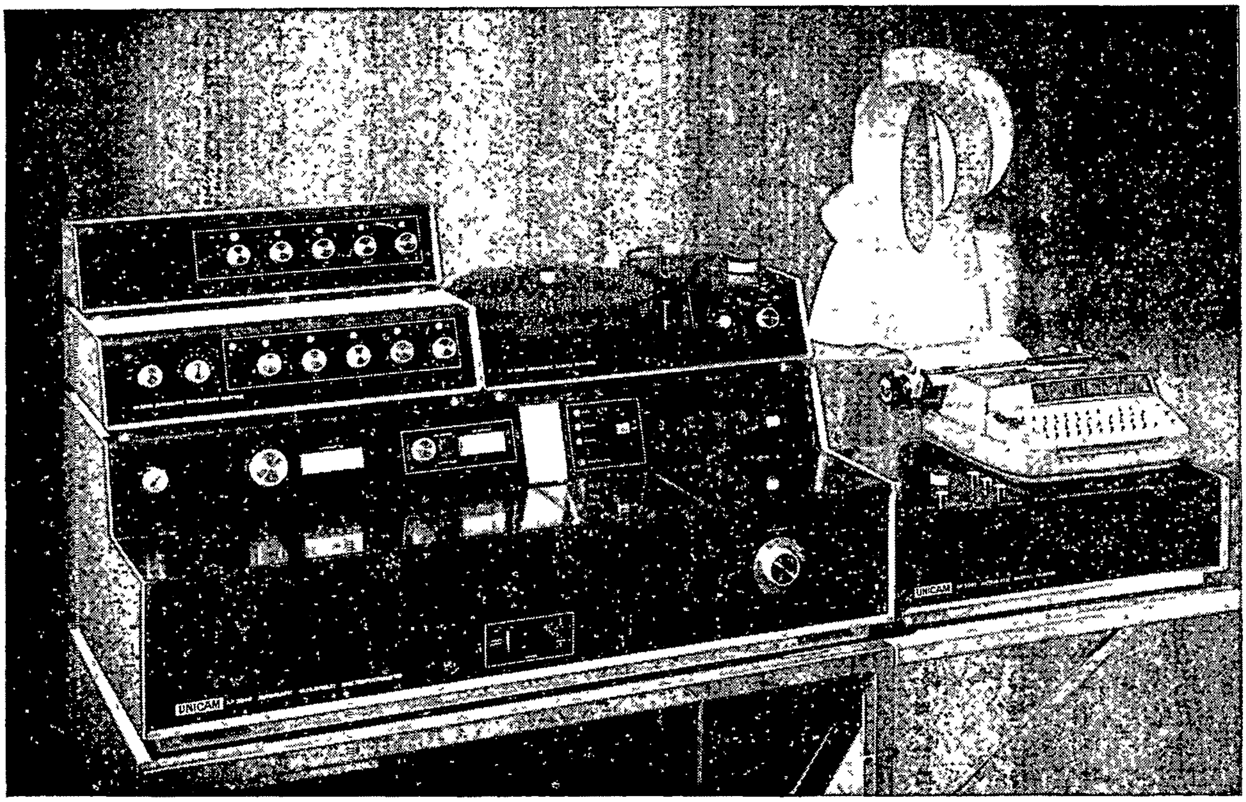
SP3000



The most sophisticated spectrophotometer in the world

The most automated The world's first with built-in digital presentation of absorbance values The Unicam SP3000 ultraviolet and visible spectrophotometer

The SP3000 automatically measures from one to 50 samples at up to 10 different wavelengths

The instrument presents absorbance or transmittance on a built-in illuminated digital display The reading is printed simultaneously on an electric typewriter

For accuracy the SP3000 depends on a new and unique photometric system which uses single beam optics together with an auxiliary radiation standard This eliminates errors due to unbalanced beam geometry or photomultiplier gain drift Automatic calibration before every measurement ensures high accuracy—readout resolution is 0 1%T or 0 001A And reliability has been thoroughly proved in a comprehensive programme of field trials

Further details of the SP3000's outstanding performance are contained in a technical brochure

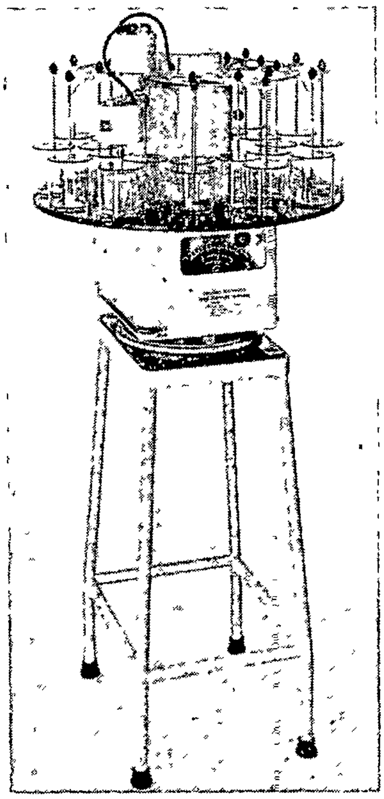
"Hendrey" Automatic Slide Staining Machine



Based on the well-known Histokinette Automatic Tissue Processing Machine, the new "Hendrey Automatic Slide Staining Machine offers the same degree of simplicity and efficiency, combined with ease of operation and considerable savings of time and labour

The new machine dramatically eases the burden of manual staining for the Laboratory Technician involved in an increasing work load in exfoliative cytology, and allows staining to proceed automatically and with very little supervision

The most important feature of the machine is the great accuracy of staining and consistency of results obtained with it The provision of 23 covered beakers on the machine means that it is eminently suitable for the Papanicolaou staining process, but the machine can be used to stain any specimen which can be mounted on a microscope slide, and it can operate other staining processes provided that not more than 23 stations are required in the complete cycle

The slide carrier accommodates 36 standard microscope slides in one load and uniform staining is ensured by the combined perpendicular and rotary movement which is employed during the time that the slides are immersed in the various staining liquids

Full details available on request

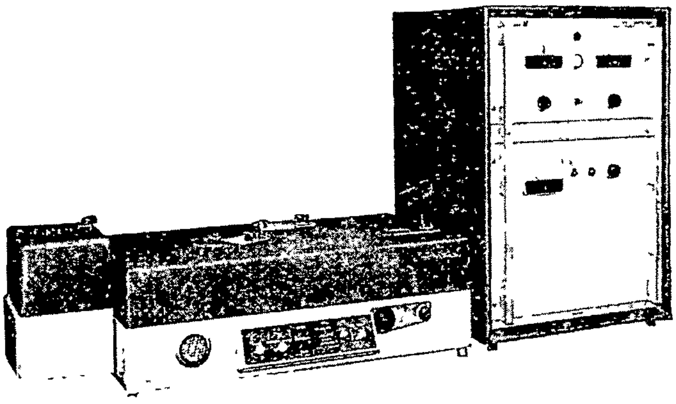
The POLARMATIC 62 Automatic Spectropolarimeter



NOW O.R.D + C.D

We are pleased to announce that a Circular Dichroism attachment has been designed by the National Physical Laboratory and will shortly be available for this outstanding spectropolarimeter. Like the Polarmatic itself, this new device will once again open up new thresholds in biological research

A great deal of engineering development has enabled us to offer this attachment to both new and present users of the O.R D. instrument. For full details write to Dept. N

We now have capacity for aluminising certain types of mirrors, at short notice

Less Money to Spend

THERE is very little to cheer about in the United States budget for 1969 (see page 505), although there may be some relief among scientists that several conspicuous projects have survived more or less unscathed the wave of parsimony which has swept through the Federal Government in the wake of the Vietnam war The new proton accelerator at Weston in Illinois will be built on time (or perhaps even sooner, to judge from the vigour and the cleverness with which Dr Robert Wilson and his colleagues have embarked on the detailed design work now in hand) Expenditure on defence research will also increase, though principally because of the decisions taken in the past few months about the development of new kinds of weapons systems—the anti-ballistic missile system, for example

With economy in the air, it is unlikely that much of the extra money being laid out by the Department of Defense will spill over into other fields—indeed, there is a serious danger that the economies will actually diminish the amounts of money which the armed services have been accustomed to spend on the support of comparatively academic research in the United States Nobody should be surprised if that happens, for it has been clear for some time that over-dependence for research funds on what the military departments can afford to spare from their large budgets is potentially too dangerous for comfort, to say the best about it. In the same spirit, it is not remarkable that NASA, in its quite understandable attempt to preserve for itself as much freedom of manoeuvre as possible for the period after 1969, should have chosen to economize by cutting back on what it proposes to spend on strictly scientific work

It remains to be seen how these economies will be apportioned between the companies which build and launch satellites and the teams of people in the universities responsible for the design of instruments and the interpretation of results, but here again there is a danger that the universities will find themselves bereft of funds on which they have become accustomed to rely If next year Congress should be as eager to reduce the Administration's requests for funds as it has been in the current financial year, the consequences for American universities could be quite serious

So what, then, should be done? At this stage no purpose will be served by wringing hands about the prospect of misfortune The reasons for the financial stringency which has come on the United States are plain enough for most people to see, and much as many people would like to see them go away, there are few who would pretend that the full weight of policy-making in the United States should be exclusively determined by a concern for the health of fundamental science Moreover, it is only seemly to acknowledge that there has been no serious interruption of the tendency, which has become apparent in recent years, for the Federal Government to shoulder increasing responsibility for the welfare of higher education The consequences are most clearly to be seen in the continuing growth of financial support for university students, graduates and others In the long run, universities in the United States can only profit from still further developments along these lines, for some sharing of the cost to students and their families of four years at a university is a necessary means of making sure that all the people in need of university education eventually find their way there

By the same test, however, American universities, already jealous enough of their independence, may take recent experience in Britain as a further warning of the risks of Federal subventions for buildings and other facilities Whether state governments or the nostalgia of alumni are invariably preferable to the Federal Government as sources of support is another issue, of course, but even in the United States the entirely independent university is almost a thing of the past The point which emerges most clearly from the new budget is that the fabric of university teaching in the United States will not be unduly cramped by what has happened

The pinch will be felt in the research laboratories, and the most constructive course to follow will be to seek the kinds of structural changes in the machinery for supporting fundamental research which are likely best to serve the long-term interests of fundamental research, both in the universities and elsewhere The most urgent need is to re-examine the intervention of the mission-oriented agencies in the support of fundamental research—which does not imply that the Office of Naval Research was anything but far-sighted when it embarked on its academic programme of research after the war, that the Atomic Energy Commission is in any way deficient in its role as indulgent uncle to laboratories such as the Brookhaven National Laboratory and provider of cyclotrons to the universities, or even that the Department of Defense is malevolent in seeking to foster centres of excellence at the universities by supplying funds under what it calls Project Themis The big-spending agencies have done a splendid job in the past two decades, but there are now a great many reasons for believing that the agencies should play a smaller part The fact that science budgets tend, at present, to be marginal budgets is the immediate reason for thinking this It is, however, much more important that in present circumstances there is no ready means by which the intentions and the ambitions of the several agencies can be compared effectively with each other And in the long run the United States as a whole should profit from some machinery for making sure, for example, that a reasonable wish to embark on a programme of space research should not be followed by some of the extravagances which have marked the past few years In other words, the goal should be an independent agency able to make decisions about the commitment of resources in the whole of fundamental research and with the power to spend money as well.

This, of course, is where thoughts turn naturally to the independent agencies—the National Science Foundation and the National Institutes of Health On paper, at least, both of them seem to have done reasonably well Both of them will have a little more money, and the extra $24 million on the budget of the National Science Foundation works out at something like an increase of 5 per cent In practice, however, this means an increase of merely $14 million on what the foundation has to spend on basic research, and there is no question that the $230 million at the foundation's disposal is too small a proportion—10 per cent—of the federal money which finds its way into research at the universities This anomaly is particularly galling when it is acknowledged that the foundation spends nearly as much on the support of science teaching as on research, and that the cost of what are called supporting services—information handling and forward planning—had already passed $50 million a year ago This is not, of course, to suggest that these activities are not good works, although it is probably too late for the National Science Foundation to recapture the coordinating functions which have long since been assumed by the Office of Science and Technology There is, however, a real danger that the tail will wag the dog, or even that the dog itself will altogether disappear

But the National Science Foundation is too weak to occupy the centre of the stage This is the customary explanation of its lowly position in the pecking order The truth is that some of this weakness is internal—and remediable—and that some of it is a simple consequence of the way in which the mission-oriented agencies act as patrons of the sciences on a lavish scale The Daddario Bill, which has been hatching in Congress so long as to suggest that it may now be addled, will not tackle this problem, and it is only fair to acknowledge that a good many influential officers of the Administration, especially in the Office of Science and Technology, do not see it as a problem at all In practice, however, it will be a great misfortune if the year ahead, which may well see the retirement of Dr L Haworth, the director of the National Science Foundation, is not also taken as an opportunity for a massive strengthening of its position

Physicists and Public Issues

THE American Physical Society seems to be making heavy weather (see page 502) of the proposal by Dr Charles Schwartz that members of the society should be allowed to raise political issues at meetings and in various publications of the society It needs very little clairvoyance to know what kinds of issues Dr Schwartz and his supporters wish to raise, and it would, of course, be wrong to suggest that physicists should be less concerned about matters such as the war in Vietnam or the construction of anti-missile defences than other professional groups—sinologists, for example, or radio engineers It would also be wrong to diminish the importance of some of the issues which Dr Schwartz and his supporters have quoted as potential subjects for public discussion within the American Physical Society What is happening in south-east Asia, for example, may well become a turning point in modern history It is also inevitable that political developments of various kinds—the costing of a budget, for example—can be of vital importance for the profession of physics But this, of course, is not the point The immediate question is the extent to which great learned societies should engage in the public discussion of important public issues Although there is very little doubt that Dr Schwartz and his supporters are making an unacceptable request, the issue is interesting and also important They have done a public service in bringing it into the open

There are several interlocking questions to be decided, but the one which has most often been overlooked in the debate in *Physics Today* is the proper function of a learned society In the last resort, a society is a kind of club Its existence stems from the common interests of its members To begin with, for example, most learned societies come into existence because there is a need for channels of communication between people concerned with similar academic problems The members may have bitter disagreements among themselves about all kinds of subjects—the correctness of a theory or the size of the subscription fee—but they are bound together by their common need of some means of expressing opinions to similarly interested colleagues With the passage of time, several developments may come about There is, for example, a tendency for large societies to spawn sub-societies within themselves in response to the development of new specialized interests

It is also natural that the interests of many societies should often grow beyond the academic confines in which they are launched Physical societies naturally interest themselves in questions such as the supply of trained manpower and the salaries of professional people, for example, for these, too, are issues on which the members of the societies may fairly be said to have a common interest As committees are usually well enough aware, however, even a few dissenters are enough to bring a new venture to a halt. That is as it should be, for it would be self-destructive of a society to follow a course which alienated even a handful of serious members This is the sense in which Professor

Orear is mistaken to claim that silence implies acquiescence Often it means just busyness By the same test, it is mistaken of Dr Schwartz to think that the agreement of one per cent of the membership of a society is a sufficient mandate for new undertakings Ninety-nine per cent would be a better figure from which to open negotiations But with that reservation, there is no need artificially to restrict the scope which learned societies should choose for themselves If they wish to become pressure groups, there is no reason why they should deny themselves that luxury, and it is, of course, delightfully disingenuous that Dr Edward Teller, who has been a one-man pressure group on defence policy for several years, should now maintain that pressure groups are a nuisance Where societies are concerned, what matters is what most members want

There remains the question of how physicists in the United States should set out to tackle the kinds of questions which Dr Schwartz would like to raise within the American Physical Society The first thing is that if there is a group of physicists which feels a need to take a special interest in public issues, and if it considers that it has something special to contribute, there is no reason why it should not form a society specifically for that purpose In time it might even establish a reputation for responsibility and good sense.

Fast Reactors in Europe

The European Nuclear Energy Agency celebrated its tenth anniversary in Paris last week with the cheerful announcement of a plan to investigate the building of a fast reactor as a joint project It has been decided to set up two working parties—one technical, one more directly industrial—on fast reactors The formation of the technical group was prompted by the uneasy feeling that fast reactors have so far been developed on too narrow a front. Hitherto it has been assumed that the best method of cooling is by pumping liquid sodium around the reactor At the back of people's minds has been the feeling that perhaps gas or steam would do the job equally well Although those who have invested in fast reactor development already, including the UK Atomic Energy Authority, have presumably satisfied themselves on the point, the delegates at the recent meeting in Paris saw no harm in making doubly sure The working group will therefore be making a technical study of the two systems, and comparing them with sodium cooling The group will report back in June, and if there then seems a need to go ahead and produce some hardware, this could be set in motion by the end of the year Much will, of course, depend on the reaction of individual countries to the report

The other working party has been set up with the intention of taking early industrial soundings about possible fast reactor projects Its aim is to devise ways in which any joint reactor development undertaken by ENEA could be smoothly handed over to industry when it is complete One delegate at the ENEA meeting described the formation of this group as one of the fruits of the Dragon project Dragon is coming to an end without as much industrial follow-up as some people consider it deserves Happily, there are some signs of interest, five European companies have joined forces to consider the formation of a European organization to promote the sales of reactors using Dragon high temperature technology The companies are the Nuclear Power Group (UK), Belgonucléaire (Belgium), Gutehoffnungshutte (West Germany), SNAM Projetti S p A (Italy) and Groupement Atomique Alsacienne Atlantique (France) This is an encouraging sign of international interest in the system.

At the same time, ENEA has set up a committee whose task it will be to press forward the commercial application of heavy water reactors in Europe Although almost every conceivable variety of heavy water moderated reactor has been designed—and a number have been built—electricity utilities have tended to fight shy of them The new group will attempt to break through this consumer resistance, fortified perhaps by the knowledge that the British example of the breed, the steam generating heavy water reactor at Winfrith, reached its full design capability of 100 MW late last month The UKAEA, which designed and built the SGHWR, has its own ideas about selling it, and has prepared a contract in collaboration with Finnish industry to supply an SGHWR to Imatran Voima Oy, the Finnish electricity utility

Money for British Postgraduates

The Department of Education and Science is thinking of transferring all responsibility for postgraduate awards to central government Consultations are in progress with the Committee of Vice-Chancellors and Principals, the Association of University Teachers, the Association of Principals of Technical Institutions, the Association of Teachers in Technical Institutions, the National Union of Students and the National Society of Art Education

At present these awards are made by various departments, including the Department of Education and Science and the Scottish Education Department, as well as by research councils and local education authorities in England and Wales Although local education authorities can, in fact, make awards in any field—even to cover research leading to a doctorate of philosophy—the awards are usually provided to cover vocational courses such as diplomas in management studies, or for polytechnic courses These awards are financially similar to the ones provided for first degree courses and are assessed according to parental income

The Secretary of State for Education and Science, Mr Patrick Gordon Walker, has told local authorities that the present division of responsibility is causing increasing difficulty to applicants, academic authorities and award-making bodies In 1966, at the annual conference of the Association of Education Committees, a resolution was passed calling on the Department of Education and Science to assume full responsibility for awards for postgraduate study apart from those studies of a strictly vocational nature

Mr Gordon Walker adds that this proposal is not concerned with the total number of postgraduate awards made from public funds but simply with "the most efficient and economical way of administering them" He further maintains that until the idea of central control is completely acceptable, there is no point in considering in detail the way in which this might be brought about

Controlling Drugs

THE Medicines Bill published in Britain this week (H M S O, 10*s* 6*d*)—less than five months after the Sainsbury Committee's report on the relationship between the pharmaceutical industry and the National Health Scheme—proposes a number of controls and safeguards in the importation, marketing and retailing of medicinal products One of the principal decisions made is to appoint a Medicines Commission with eight members from medicine, veterinary medicine, pharmacy, chemistry other than pharmaceutical chemistry, and pharmaceutical industry This body will advise on matters relating to the administration of the Bill or, generally, in relation to medicinal products, but it will also be required to advise on the pattern and membership of expert committees

The Bill also follows the Sainsbury Committee in laying down that a "product licence" will be required before any medicinal product can be marketed in Britain, regardless of where it is produced Doctors, dentists and others will, however, be allowed to continue making up their own mixtures, but veterinary surgeons and practitioners will have to comply with certain standards on vaccines and sera

Applications for and renewals of licences will have to be made to the licensing authority, which will take account of factors such as safety, efficacy and quality in relation to product licences, the facilities and control arrangements in relation to manufacturers' licences, and premises and storage facilities in relation to wholesale dealers' licences Requests cannot, however, be refused on the grounds of selling price and, indeed, refusal on any grounds can only be enforced after consultation with the appropriate committee or the commission The licensing authority will be able to reserve the right to suspend licences on a number of grounds—for example, if the standards to which a product is manufactured are no longer satisfactory A product licence or certificate will also be required before clinical and field trials can be carried out, and the risk involved will have to be considered by the licensing authority Moreover, every clinical trial certificate will expire after two years but can be renewed on application The question of including medicinal products in animal feeding stuffs is also covered in the Bill, this will only be possible in accordance with the conditions in a product licence or field trial certificate Ultimately it will be for the Minister of Health to specify which medicinal products are safe enough to be sold without the supervision of a pharmacist

According to the Bill, subject to certain provisions it will now be an offence for any commercially interested party to issue advertisements that are false or misleading This provision replaces the one in the Food and Drugs Act with respect to false and misleading advertisements for drugs Furthermore, the Bill allows regulations to be made concerning the particulars in an advertisement, the form and manner of presentation, and in addition it enables the licensing authority to call for copies of advertisements Persons other than licence holders will not be able to issue advertisements without the consent of a licence holder, and a fine not exceeding £100 will be imposed on anyone contravening this restriction Copyright in the British Pharmacopoeia may pass from the General Medical Council and be assigned to Her Majesty future editions will be prepared by the Medicines Commission or an appropriate committee under its direction, and the editions will then be published by the ministers on the Commission's recommendations

Obviously the success of the Bill will depend on how strictly the new regulations are followed Those who fear that the new Bill is unduly restrictive should perhaps look at the United States where the Committee of the National Academy of Sciences is giving the Food and Drug Administration a sharper bite than it has had in the last few months

The Government Inspector

THE Comptroller and Auditor-General began his visits to British universities last week First on the list was the University of Sussex at Brighton, to be followed by the University of Lancaster In spite of the cries of horror which greeted the announcement some months ago that the universities would now be subject to an audit by the comptroller and his staff, the occasion seems to have passed off without incident

The Exchequer and Audit Department, which is responsible for carrying out the audit, seems not yet certain exactly how it is to be done "We're feeling our way," one member of the staff explained But the general pattern of visits seems likely to be that two members of the staff will visit universities for about two weeks at a time, and quite literally examine the books Surprise visits are definitely not on—"We always notify the universities in advance" It is thought that about a dozen universities will be examined each year, which means that the whole lot will be covered in about four years But more frequent visits are not ruled out—it all depends how difficult the job turns out to be A new section has been set up at the department specifically to deal with the task

Scientists Redundant

THE angry reaction to the news of AEI factory closures seems to have made the giant GEC cautious in its dealing with its research workers Following the announcement that the telecommunications laboratories at Blackheath and Harlow are to close came the statement that work would be transferred to other research establishments at Coventry and Wembley, where more technicians would be needed as well as a "substantial number of engineers and scientists" Official comment suggested that the company would be more occupied in persuading people to move with them rather than in pacifying the ones who will be redundant This may indeed be the case for some of the older men, particularly in the development engineering section, because some of them have had to move several times already, to keep up with reorganizations For the rest, it is believed that offers of employment will be made to selected staff only

The closing of the Harlow sections comes as the third and final stage of reduction Originally the laboratory served three sections of AEI with a staff of 300 working on radio, sales and telecommunication In 1963 the radio interests of the company were sold, work on semiconductors and transistors ceased and total staff fell to about 180 The cables section was withdrawn in 1966 and the remaining staff of 140 remained for telecommunications Rather than being involved in the expertise of the subject, the group has concentrated particularly on the materials science side, working on advanced materials and developing microelectronics It is thought that a few workers will be offered posts at Wembley, where fundamental work in this line is carried out, but GEC already has a well established group working on materials science There is also a group at Harlow which is just getting going onto production engineering and automation, and it is feared that the GEC is just not interested in this

It is highly likely that a similar story would emerge from the Blackheath laboratories, but GEC is trying to restrain comment The statement that the company is to build up powerful research teams, particularly at Wembley, is being received with scepticism by some of those affected

New Man at Harwell

DR WALTER MARSHALL is to succeed Dr Robert Spence as director of the Atomic Energy Research Establishment at Harwell on April 1 One of his principal tasks will be to supervise the practical and commercial assistance which the establishment hopes to give to industry in Britain

Dr Marshall, who is 35, joined the AERE in 1954 and became head of its theoretical physics division in 1960 He was appointed deputy director in 1966 Dr Spence became head of the chemistry division at Harwell in 1946 and has been director since 1964 He now goes to the University of Kent to take up the mastership of the new third college, as yet unnamed, and the chair of applied chemistry

New Man in France

THERE is great pleasure in France that the new head of the Délégation Générale de la Recherche Scientifique et Technique is Dr Pierre Aigrain, until this week in charge of higher education at the Ministry of Education Dr Aigrain is 43 and is a physicist by origin and since 1959 has been secretary-general of the French Physical Society His career has alternated spells in government departments with intervals of academic life He has, for example, held scientific positions with the French navy, the atomic energy commission (CEA) and, most recently, the army He was at the Collège de France for a brief spell in the early fifties and has been connected with the universities of Lille and Paris He has won himself a high reputation as an energetic and sensible man

Physics Information

THE American Institute of Physics has landed the first instalment of a grant from the National Science Foundation which is likely to amount to more than a million dollars in the next five years and which will be spent on the study and development of new techniques in the dissemination of information in physics Work has already begun on the project, which was described at the New York meeting of the American Physical Society at the end of January by Dr H W Koch, director of the American Institute of Physics Like the American Chemical Society, the American Institute of Physics, which is a federation of several learned societies ranging in size from the American Physical Society to the Society of Rheology (with a few hundred members), has come to occupy a central position in the publication of original material in physics Dr Koch said that the institute's journals have been publishing more than 50,000 pages in aggregate each year for several years now The total size of all its journals seems in fact to be doubling every five years The American Institute of Physics is perhaps more outspoken than other similar organizations in its belief that there would be benefits in devices which could replace formal publication

The plan for the information study now begun will cover several aspects of this problem For one thing, there is to be a thorough study of the uses of computers in the storage and retrieval of information In this sense, the Institute of Physics will be following the Chemical Abstracts Service, which is now publishing lists of titles on magnetic tape It seems, however, to be acknowledged that physicists may not be as well served by computer storage as are the chemists—for one thing the costs of tape retrieval seem to be high and informal exchanges of preprints among interested groups of physicists have been well developed But the Institute of Physics is also hoping to tackle directly the qualitative problems of the scientific literature, and the programme of work ahead is to include a serious attempt to decide what part formal articles in the scientific journals should play in the dissemination of information A convincing answer would be well worth a million dollars

Doctorates in the United States

A STATISTICAL report on the education and subsequent employment of PhD students and their equivalent in the United States has been published by the National Academy of Sciences for the Office of Scientific Personnel of the National Research Council (*Doctorate Recipients from United States Universities, 1958–1966*) The source of all the information is the Documents Records File which is compiled from extremely detailed surveys of graduates completing doctoral degrees This file goes back to 1920 and must surely be the envy of higher education authorities in other countries for its thoroughness All subjects are covered in the report, though there is no doubt about the predominance of science and technology In 1966, a total number of 17,865 graduates received doctorates, of which 6,077 (34 02 per cent) were in physical sciences and engineering, and 2,869 (16 06 per cent) were in biological sciences A further 2,666 (14 92 per cent) were awarded doctorates in the social sciences Altogether there has been an average growth rate of 9 2 per cent over the period 1958–66 Engineering has had the most spectacular increase—in 1966, four times as many doctorates were given in this field as in 1958 Corresponding to the growth in numbers of PhDs are figures for the growth in numbers of colleges and universities There is also a detailed analysis of the pattern of doctoral education—the time taken to register for higher degrees after completion of first degrees, transference from one course to another and from one institution to another during the period of study and so on

Of interest to the followers of the Swann and Willis Jackson reports on scientific and technical manpower are the analyses of postdoctoral employment Colleges and universities are the main employers of higher degree graduates in all fields and a greater percentage

Table 1 FIRST EMPLOYMENT OF HIGHER DEGREE GRADUATES IN THE USA

Field of doctorate	Year of doctorate	College and university	Elementary and secondary school	Government	Non-profit	Industry	Other	Foreign employer	Total with known employer
Total all fields	1961–63	18,877	1,722	2,410	1,305	4,319	763	2,828	32,224
	1964–66	27,362	2,082	2,921	1,760	5,499	1,127	3,961	44,712
Physical sciences and engineering	1961–63	4,643	27	598	374	3,521	345	912	10,420
	1964–66	7,259	5	845	498	4,540	597	1,338	15,082
Biological sciences	1961–63	3,096	33	640	193	442	126	808	5,338
	1964–66	4,255	4	776	289	516	184	1,135	7,159
Social sciences	1961–63	3,133	143	827	372	227	191	487	5,380
	1964–66	4,328	82	833	497	255	203	610	6,808

are attracted each year This trend is especially marked in the physical sciences and engineering Industry is the major employer of physical scientists and engineers, but it employs fewer than 10 per cent in other fields The percentage of scientists and engineers with doctorates going into industry, however, has fallen rapidly from 44 per cent in 1958–60 to 30 per cent in 1964–66 Mathematics, physics and chemistry show especially sharp declines in industrial employment Fewer than 10 per cent of the new higher degree graduates accepted employment overseas, but this figure should be balanced against the number of foreign graduate students (14 per cent) in the country Brain drain enthusiasts should have fun working on all these figures

No Merger for Engineers

THE projected merger between the Institution of Mechanical Engineers and the Institution of Heating and Ventilating Engineers is off After discussions lasting the best part of a year, the heating and ventilating engineers finally decided that they no longer wished to press on with the merger The decision has left the mechanical engineers slightly baffled "We don't know why they decided against the merger" an official said this week "It's very disappointing "

Merger talks began when the heating and ventilating engineers decided that they wanted to increase their influence The easiest way of doing this, short of a royal charter which was very unlikely to be granted, was to amalgamate with an established body The obvious choice was the Institution of Mechanical Engineers, and talks began It was first agreed that the heating and ventilating engineers should enjoy a status within the combined institution much like that enjoyed by the automobile engineers They would have been virtually an autonomous group, with their own council and their own chairman, and members in the different classes of membership in the IHVE would have been able to transfer to the equivalent classes in the combined body The IHVE would have been able to publish its own journals and hold its own conferences and meetings The mechanical engineers had agreed to set up joint working parties to study the problem of technician engineers, whose position the IHVE was anxious to protect Despite all this, the heating and ventilating engineers told the mechanicals on December 20 that they did not wish to proceed

One heating engineer suggested this week that the IHVE feared that it would be swamped when it joined the mechanicals There does seem to have been some opposition within the profession, although the mechanical engineers say that they have received several letters from individual members of the IHVE regretting the decision The Institution of Mechanical Engineers denies that it ever wanted to make a takeover bid for the IHVE, and "sincerely hopes that this is not the end of the affair The door is not closed to further talks" Meanwhile, joint meetings will continue as before Clearly the hope is that the IHVE will eventually see the folly of its ways

Safety in Space

by Angela Croome

SEVERE strictures on National Aeronautics and Space Administration (NASA) complacency, which it considers was responsible for the deaths of three astronauts in last year's Apollo fire, are contained in the Congressional report of its own inquiry into the circumstances of the accident. Some of the Senate space committee are doubtful if the shortcomings of the contractors' work would have come to light without the accident, and NASA is criticized for not passing on to Congress reservations on the performance of the Apollo main contractor, North American Aviation, which was the subject of a secret NASA report in 1965 In summary, "NASA's performance—the evasiveness, the lack of candour, the patronizing attitude exhibited towards Congress, the refusal to respond fully and forthrightly to legitimate congressional inquiries, and the solicitous concern for corporate sensitivities at a time of national tragedy—can only produce a loss of congressional and public confidence in NASA programmes"

In the meantime, extensive replacement of materials in the capsule and spacesuit to make these "almost fireproof" has been completed A quick escape hatch has been substituted for the previous design The total cost of these modifications is estimated at $100 million The changes have forced the forfeit of between 600–1,000 lb in the overall weight of the spacecraft and this in turn has required the re-design of the return parachute system to support it A fully fire-resistant material, Beta fabric, has replaced high-temperature nylon (Nomex) for the outer layer of the Apollo pressure-suit The inflammable boot-soles and helmet (polyurethane) have been replaced by carboxy-nitroso rubber and a silicone material respectively Nomex has been substituted for nylon as the material of the suit liner. The opportunity has been taken to make the suit more comfortable and durable Metallized patches cover pressure points and the outside of the gloves are equipped with artificial nails or claws to assist sample collection It is estimated that about 1,000 yards will be the walking limit of an astronaut kitted out for the first lunar excursion

On its first flight on January 23 the Apollo lunar model acquitted itself well, and NASA authorities are now considering whether the other scheduled unmanned flight could be dispensed with. Premature cut-off of propulsion firings has been attributed to over-conservative programming of the on-board guidance computer and not to malfunction.

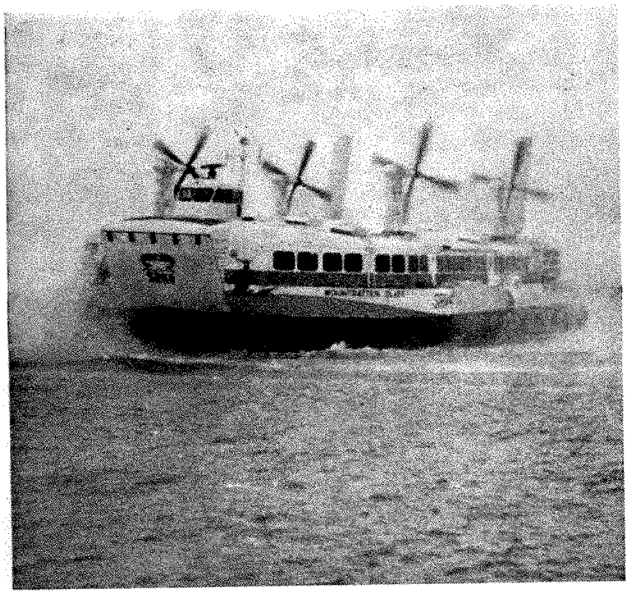
Thorough check-out of the various components of the lunar landing mission is essential, since there is considered to be no possibility of survival or rescue from an accident on or near the Moon. Dr George Mueller, director of the manned spaceflight programme, recently made clear that on the Moon there will be a 36 h oxygen supply for the two astronauts, not a large margin on the projected 22 hour stay. No rescue provisions are being made. It would take a month at least to get a relief party out there, Dr Mueller pointed out.

Nevertheless NASA has recently appointed a Safety Director whose job it will be to look into the problems of orbital rescue as well as the more conventional aspects of spacecraft and range safety. In his mid-40s, Bob P. Helgeson has had experience in atomic energy as well as with the X-15 hypersonic research aircraft programme.

Hovercraft Launched

The largest hovercraft in the world took to the water this week for its first trial. Built by the British Hovercraft Corporation at Cowes, the hovercraft is called the SRN 4, or, more grandly, the first of the Mountbatten class. It will be used as a cross-Channel ferry by British Rail and by the Swedish firm Hoverlloyd, carrying 254 passengers and 30 cars, or 600 passengers. Despite unpleasant weather conditions for the launching, the four-engined craft got away successfully, and, it seems, comparatively quietly, although so long as hovercraft are propelled by large aero engines driving propellers they are never likely to compete for quietness with muffled oars. The launching is a great moment for those who have supported the development of hovercraft in Britain, and for their inventor, Mr Christopher Cockerell, who was there to see it happen.

Sadly, it is not quite so cheerful a moment for the design staff of the British Hovercraft Corporation. The company announced this week that 40 members of the design staff working at Hitchen will be laid off over the next 2 months. The reason for this, the company says, is twofold. At the end of 1967, a number of projects which the company had hoped to start work on at Hitchen and Cowes failed to materialize. Coupled with the cuts which the Ministry of Defence has made, this has meant that design staff will have to go. Some, it is hoped, will be found work with Westland Aircraft (one of the two major shareholders in BHC). At Cowes, there should be sufficient work to sustain the design team.



The SRN4 hovercraft on its first trial.

School Mathematics

The report of the director of the School Mathematics Project for 1966–67 has a cheerful tale to tell about the acceptance of the new courses as qualifications for entry to universities. Dr Bryan Thwaites says that "with only one or two exceptions" all university departments of mathematics are prepared to accept as candidates for entry students with a pass in the Advanced level examination in what is called "SMP Mathematics". Even so, it seems, suspicions persist in the schools that a double dose of SMP is likely to be a safer means of being accepted than a single dose, and these suspicions seem to be borne out by the reaction of some of the universities to the new courses. Dr Thwaites says that "at least some university departments are going against the spirit of their formal acceptance . . ." by asking extra of intending students. It remains of course to be seen whether Dr Thwaites's exhortation will bring backsliding universities to heel.

To judge from what the report says, the publication programme is now virtually complete. This means that courses are available for students between 11 and 18. One innovation, however, is that the School Mathematics Project has turned itself into a trust which will presumably be able to superintend the further development of the teaching materials now available.

Undivided Seconds

from our Oxford Correspondent

Rather surprisingly, Congregation at Oxford has reversed its decision to divide the second class degree into upper and lower parts, a proposal accepted last term by 101 votes to 99 (see *Nature*, **216**, 631; 1967). This term's debate, on an opposition amendment that the division should be indefinitely postponed, was very much better attended. The debate, however, seemed somewhat confused, with members finding it hard to distinguish the germane from the irrelevant. There was a certain amount of doubt whether the original proposal had been to enlarge the second class as well as divide it, or merely to divide it—the two measures having rather different effects. The final vote for the amendment was 171–121, so that for some time at any rate Oxford will be making no official distinction between types of second class. What will happen, doubtless, is that fewer Thirds will be awarded, and that the Fourth Class will cease in practice to exist. So Oxford will be aligning its degree classes with those of other British universities while avoiding the difficulties of subdividing the second class candidates, most of whom would be on the borderline of the subdivision. As the second class comes to embrace all but the best and the worst, it will become more important to distinguish candidates by giving marks, and by tutorial recommendation, a system more equitable to examiner and candidate alike and one not dissimilar to the practice in universities outside Britain.

While Congregation has been discussing these moves, a group of junior members of the university has petitioned the Privy Council for changes in the procedure under which students are disciplined. At present two senior members—the Proctors—are responsible both for seeking out offenders against university regulations, and also for judging and sentencing them. The signatories of the petition are asking that the roles of police and judiciary should be separated: they propose that students should appear before a disciplinary committee to which they and the proctors would put their cases. The petition also asks that the disciplinary committee should be appointed by the Vice-Chancellor in consultation with the student council, but there is less likelihood that the authorities will accept this part of the proposal. The fact is that the university does not formally recognize junior members or their representatives, although two thousand students are graduates. It is only under an Act of Parliament, which takes a commendably tolerant attitude to their existence, that junior members are allowed to make representations to the Privy Council when new university statutes are being established. There has been no official comment on the petition from the university authorities yet.

New Man at Heriot-Watt

Dr R. A. Smith, Professor of Physics at the Massachusetts Institute of Technology, is to succeed Dr H. B. Nisbet as Vice-Chancellor of Heriot-Watt University on June 1. Dr Smith, who was born in Scotland, began a distinguished career at the Royal Radar Establishment in 1939, becoming head of the Physics Department in 1947. He took up his present chair in 1962.

At Heriot-Watt he will doubtless preside over the university's projected move from its present site in Edinburgh to Riccarton, six miles west of the city, where it will not only have room to expand but will also be less immediately under the shadow of Edinburgh University. The move to Riccarton is expected to take place in 1975, by which time the student population will have grown from 1,500 to 3,000. Whether that change will mean that people no longer ask whether Edinburgh needs two universities is another matter.

Commonwealth Universities

The United Kingdom has now replaced Canada as the Commonwealth country with most university members in the Association of Commonwealth Universities. This is revealed in the report of the association for 1966–67, in which it is announced that the admission of several new British universities brings the number of member institutions in Britain up to 43, compared with 42 in Canada.

In his introduction to the report the secretary-general of the association, Dr J. F. Foster, describes the association as mainly a service organization promoting the activities in London of its member universities in all parts of the world, including the United Kingdom. He contrasts the function of the association with that of many other international associations of universities which have as their main aim the spreading of a particular culture and encouraging studies of special questions of educational policy.

One unusual task which the association assisted during the year was the mounting of a "Retrieval Operation" by Canadian institutions. This was to persuade Canadians working in British universities to return to posts at home, and involved the sending of a party of Canadian officials to Britain. The association provided the Canadians with interviewing facilities and secretarial services in London.

The report shows that the appointments service run by the association is mostly used by members in Australia, New Zealand, Malaya and Hong Kong; this appears to be because the North American universities favour the making of an appointment after private enquiry and negotiation.

Oxbridge Admissions

A plan for studying the relationships between Oxford and Cambridge admissions arrangements and sixth form curricula in British schools has been launched with £14,000 of the Schools Council money. The operation is being financed for an initial period of two years. The investigation will be directed by Sir Desmond Lee, with a management committee consisting of Mr John Morrison, President of University College, Cambridge, Mr J. D. Mabbott, President of St John's College, Oxford, and Dr E. J. Bowen, Honorary Fellow of University College, Oxford. Sir Desmond will be retiring as headmaster of Winchester College later this year and will take up a Senior Research Fellowship at University College, Cambridge, in the autumn. In the meantime a research assistant will be appointed, and with Dr Bowen in charge of the Oxford end of the project it is hoped that work can begin in the near future.

The movement towards a broader curriculum in schools has been causing concern in Cambridge, where admission arrangements have been geared to highly specialized sixth forms, particularly those in the independent schools. A review of selection methods was thought to be necessary if the university was to continue to attract the large number of good students that it has in the past and if more entrants were to come from smaller maintained schools. The idea of a special investigation body was put forward by Mr Morrison, when the usual monthly committee on the subject was thought to be inadequate for a thorough inquiry. The scheme has grown to include Oxford because the problems of selection there are similar. Mr Morrison hopes that the investigation will reveal the extent of the problem of producing people who are prepared for the highly specialized Oxbridge courses. If there is less specialization in schools, then it will not only be the admission requirements that will need to be changed but also the content of the degree courses.

The organizers of the new project hope that the solutions which they suggest for Oxbridge may also provide something of value to other universities. Whether other universities will accept this view remains to be determined; for some years there has been some reason to complain that the existence of a special relationship between Oxbridge and the schools has set up strains elsewhere, so that an attempt to provide another special solution for the Oxbridge problem may seem a perpetuation of an existing misfortune But this may be only half the story Sir Desmond Lee is the principal architect of the Schools Council's proposal, now abandoned, that the sixth form curriculum for most British schoolchildren should consist of two principal courses of studies and a number of "minor' courses Mr Morrison, on the other hand, is an advocate of a broad curriculum based on five subjects (see *Nature*, **215**, 1329, 1967) Perhaps the Schools Council has found a way of making the principal gladiators settle their scores before tackling the more general problem of the universities as a whole

Money for Authors

AFTER years of campaigning, it looks as if British authors may yet receive royalties for their books borrowed free from public libraries So far there is no proposal for legislation, but authors have become more optimistic in the past few months The problem of paying royalties to authors—the Public Lending Right, as it is called—has been bubbling away for several years now, with occasional bursts to the surface when events help or hinder the cause Another bubble burst last week with the publication of a pamphlet, *The Arts Council and Public Lending Right* (6d , post free from the Arts Council)

This sets out the council's interest in the subject and outlines a scheme it proposes for a Public Lending Right (PLR) When the council set up its Literature Panel in 1966, one of the first steps was to appoint a special working party and its report was approved and adopted by the council in 1967 Because the money needed would have to come from public funds and government legislation would be necessary, the council has formally submitted the report to the Department of Education and Science It is anybody's guess if and when the Government will promote the necessary Bill It could possibly make the next parliamentary session, but authors fear that PLR will hardly rate among the top priorities

Authors have long been aggrieved that there is no equivalent of the Public Performing Right to cover the lending of books from public libraries Composers, publishers and authors receive fees for the performance of any work, musical or dramatic, in addition to the sale of the original publication In effect, authors believe that Public Lending has become the equivalent of Public Performance They feel that the recent development of the public libraries, which now lend about 500 million volumes a year, has taken place without anything approaching commensurate return to the producers of the books A recent survey drew attention to the plight of some authors Few earned anything like enough money to live on from their writing alone It is also argued that organized lending radically affects the economics of book publishing One library book may survive 200 issues (with one rebinding) from which the author would receive one single royalty payment and the publisher a comparable sum, from the original sale

Earlier schemes have involved payment to authors by libraries based upon the number of times the book is issued, and the money has been obtained from small charges to borrowers Librarians were, however, opposed to that scheme, two Government Bills were defeated and the subject was omitted from the 1964 Public Libraries Act Librarians argued that to charge borrowers was an abandonment of "free" public libraries, that any payment to authors by libraries would involve administrative costs to the detriment of book stocks, and that the development of public libraries helped, not hindered, book producers

In the new scheme, a system would be devised on the Danish model, using book stocks as its basis, rather than book loans as found in Sweden It is proposed that a Library Compensation Fund Committee should be established to administer a compensation fund, which would be supplied by an annual grant paid to the committee from public funds The size of the grant would be related to the total annual expenditure of Public Library Authorities on books Payments to authors and publishers would depend on the stocks held in public libraries It would be impractical for all libraries to send returns of stocks, so it is proposed that only sample libraries (three in England, for example) would send figures These stock figures would be compared with the total of stocks held by all libraries The fund committee would work out which books qualified under the scheme and it would then calculate the rate of compensation payable per volume

The scheme appears to be more easy to operate than earlier suggestions, but reservations about the scheme remain The sample of libraries, only three per year, is very small and hardly representative Only public libraries are represented, not all libraries Stock taking by the sample libraries will still be difficult, especially now that many libraries no longer keep such detailed records How will the fund committee decide which authors should benefit ?—British copyright books include a number not written by British nationals Computerization of records for administering the fund might be possible now that books published since October last year have a standard book number, but this would exclude the thousands of books published previously These points will all have to be thought out in detail by the Department of Education and Science if the scheme is to work

New Abstracts

A NEW abstracts journal, *Metals Abstracts*, has begun its monthly appearance with an issue for January 1968 The journal is published jointly by the Institute of Metals, London, and the American Society for Metals, Cleveland, Ohio It replaces the *Review of Metal Literature* and *Metallurgical Abstracts*, the respective publications of the two societies, which will now cease Overlap between them was in fact considerable, and the new journal is a rationalization which should benefit both its producers and its users

Metals Abstracts aims to provide a complete coverage of the world's metallurgical literature, and will in fact contain almost twice the number of abstracts that appeared in the British *Metallurgical Abstracts* Industrial users in Britain may regret, however, that its price to them has also increased, the former will cost £116 ($280) a year, while the latter cost £20 For libraries the cost of *Metals Abstracts* will be £41 ($100) and for members of the societies £10 ($25) Monthly and annual indexes will be provided for additional fees

The new journal is produced and printed in Britain, the index, compiled by a computer, is produced in the United States.

Physicists and Politics

The discussion of public issues by scientists is less rare in the United States than in Britain, where lips are usually sealed—in public, at least. But despite greater individual loquacity in the United States and the existence of several scientific journals which devote themselves to a discussion of public issues (*Scientist and Citizen* and *The Bulletin of the Atomic Scientists*, for example), the learned societies have so far kept their meetings and their journals free from controversial issues such as the war in Vietnam. But if Dr Charles Schwartz of the University of California at Berkeley has his way, the American Physical Society will soon change all this. He has proposed to the society an amendment which would allow discussion of any issue if one per cent of the membership of the society wished it. The suggestion was discussed at the APS meeting which has just finished in Chicago, and now goes to a full ballot of the membership of the society.

Predictably enough, the issue has roused passions on both sides. Dr Schwartz himself has had a brisk wrangle with the editors of *Physics Today*, an APS publication, about whether it should publish an account by him of the proposed amendment. His letter, eventually published along with others which give both sides of the issue, says that "there exists a whole range of issues where the technical activity of physicists gets tied up with political decision making". Unless physicists can make their opinions clear, Dr Schwartz says, they deserve to be judged by the dictum "silence implies consent". Dr Jay Orear, of Cornell University, who is chairman of the Federation of American Scientists, agrees. He thinks that scientists have a duty to protect the public from scientific hoaxes, large or small, and suggests that the establishment of an anti-missile defence system is a suitable place to start.

Dr Karl K. Darrow, however, the secretary emeritus of the APS, has other ideas. "The society has lived, thrived and done immeasurable service to physics under constitutions that limit its object to the advancement and diffusion of the knowledge of physics." Besides, opening the society to political discussions might endanger its tax-free status, he thinks. Edward Teller, from the Lawrence Radiation Laboratory, makes a more philosophical point. He says that pressure groups which exist in the United States have not been a beneficial addition to the constitution. Although, as he says, "it is a widely accepted thesis among physicists that they know best and should be consulted on every occasion", he thinks that physicists do best by keeping quiet, except on rare occasions when politicians make outrageous statements. Dr Frederick Seitz, president of the National Academy of Sciences, says that physicists have "countless avenues outside their profession through which they can express their views". He opposes the amendment, but sees no reason why *Physics Today* should not be used for some measure of social or political comment on subjects immediately related to physics.

In Britain, nobody has ever suggested that the Institute of Physics and the Physical Society (as it likes to call itself) should go in for political discussion, and Dr L. Cohen, secretary of the society, sounds enormously relieved that this is so. "There's a difference in temperament, and, of course, we don't have the Vietnam war," he says, explaining the apparent indifference of British scientists. Nevertheless, there is occasionally a need for careful management—the CERN 300 GeV machine, for example, is now as much a political as it is a scientific decision. Political discussions, he feels, would be a disruptive influence on the society, which already has to weather the tensions which result from a membership of both academic and industrial physicists.

Wellcome Foundation

For the first time the Wellcome Foundation—parent of three groups of companies: Wellcome or Burroughs Wellcome, Cooper, McDougall and Robertson Ltd., and Calmic Ltd.—is making public its full annual report and accounts, containing a ten year record. The figures show that world-wide sales for the year ending August 31, 1967, reached a total of £50·5 million, an increase of just over 15 per cent on the previous year. And Sir Michael Perrin, chairman of the foundation, records profits before tax of £6·39 million—an increase of 12·4 per cent. Furthermore, it seems that the effects of devaluation will on the whole be to the advantage of the foundation, because of its large overseas investments.

All profits received as dividends by the foundation are channelled into the support of medical research. Expenditure by the group last year on research and development was £2·86 million. One particular product of the group's commercial research during the year was the discovery of allopurinol, a drug which is used for the control of gout. A new scheme, mentioned in the annual report, will provide for all research and development within the group to be centrally controlled and co-ordinated—a scheme which, it is hoped, will extend business and increase the profitability of the group.

Research of a non-commercial nature is supported by the Wellcome Trust on a generous scale, and it has recently announced that a renewed grant of up to £36,000 is being made to two British parasitologists—Dr R. Lainson and Dr J. Shaw—to support their work in Belem, Brazil, on the epidemiology of cutaneous leishmaniasis. This is an insect-transferred disease causing extensive facial disfigurement.

The first grant of £47,500 was made in 1964, and the decision to renew the grant was prompted by the encouraging results that have been obtained. Both Dr Lainson and Dr Shaw have worked on leishmaniasis in other parts of the world, but they chose Brazil for this particular programme because of the high incidence of the disease there and because of its particularly disfiguring effects—extensive destruction of the nose and parts of the throat. Together they have confirmed an earlier suspicion that the organism *Leishmania* is transferred to humans by a particular species of sandfly of the genus *Phlebotomus* from the primary host, which they have shown to be two species of forest rodents.

Although Dr Lainson believes that it is possible for an individual to develop immunity to the disease, very little is known about the details of the immunology and it has so far proved extremely difficult to detect antibodies in the blood of immune individuals.

Cigarette Maker's Puff

BRITAIN's three million anglers are by their numbers a tempting bait for any producer of mass consumer goods. This has not escaped the attention of John Player and Sons of Nottingham, makers of Players No. 6, a brand of cigarettes.

Last week Players moved into a country hotel on the Thames to launch its "£10,000 Research Scheme to Help British Angling". The research scheme, a grandiose venture indeed, calls for a team of fisheries experts to cross the Channel and spend a whole three weeks in Holland, Belgium and Germany, where they will examine continental methods of conserving fish. On their return they will apply their findings for the benefit of British anglers. The team will be accompanied by a film unit which, to plagiarize the firm's own publicity, will make a "colour documentary film showing the work and findings of the delegation, to be available at lectures and on free loan to all angling clubs".

Some may suppose that a search of the scientific literature would with greater efficiency reveal any startling continental advances in fish conservancy. But such an endeavour would hardly make the subject of a film, prominently sponsored by Players and on free loan to all angling clubs. It is also hard at first to see why Players is contributing only £1,000 to the £10,000 "research" scheme and allowing the rest to be raised by angling competitions throughout Britain. But the prizes for all these competitions are being donated by Players, which is unlikely to take pains to conceal its generosity.

The fact that the scheme will take people out into the open air doubtless explains why the Minister of Sport sent a representative. He went as far as to say that "This is a great new development in the angling world, and Players are to be congratulated on their public spirited action in launching the scheme". Other members of the British Government, who have banned cigarette companies from advertising on television, and who intend to prevent them from giving away coupons with their products, may not feel quite so cheerful about the scheme.

Measles Vaccine

THE Ministry of Health will launch in May a campaign to vaccinate against measles all children between the ages of 1 and 15 years who have not yet contracted the disease. Trials carried out by the Medical Research Council, and experience in the United States and elsewhere, indicate that the vaccine is highly effective and that its widespread use could lead to the eradication of measles as a childhood disease. Measles is a biennial epidemic and reported cases in an epidemic year, of which next year in Britain is one, may rise to 750,000. For most people the disease is mild, but about one person in a hundred has to be admitted to hospital and in some cases the disease may be fatal; between 1962 and 1966 there were 434 deaths attributable to measles.

The cost of the campaign is expected to be about £1 million during the first year if the maximum number of susceptible children—between 3.4 and 4 million—come forward for vaccination. In each subsequent year there will be about 800,000 newborns to be vaccinated in their second year of life. The money saved from not having to treat measles in the population is expected to cover amply the costs of the vaccination campaign. It is not yet known what period of immunity is conferred by the vaccine, but it is thought unlikely that booster injections will be necessary. Antibodies have been detected in children's blood up to six years after vaccination.

Children in Britain are already offered immunization in their first year of life against diphtheria, tetanus and whooping cough—these vaccines are injected together in a single "cocktail"—and against polio, which is given orally. Vaccines for smallpox, and now measles, are given in the second year of life.

Health in Vietnam

by Anne Clayton

NOT least among the troubles of the population of Vietnam is the increasing incidence of plague, cholera, typhoid and other dengue-like diseases. These infections increase wherever there are large-scale uncontrolled movements of the population. A preliminary report on the subject has now been prepared by the World Health Organization. It indicates that there is a grave danger that infections may spread to other nations of the Pacific basin. The report, prepared during the past six months at the request of the World Health Assembly, was designed to answer several questions. Is there evidence of deterioration in the level of general health of civilian populations? Have the health services been adversely affected? Has a situation arisen in Vietnam which creates potential health hazards or problems for other countries? Any report of this nature is necessarily incomplete, but in view of the many difficulties faced by the investigators the report is a commendable effort.

For South Vietnam, the information has been provided by the official records of the WHO, WHO Epidemiological and Vital Statistics Reports, the Government of South Vietnam through the Regional Office for the Western Pacific and by reports received by the WHO quarantine unit. The account of the situation in North Vietnam is based on more limited information contained in a number of booklets which have appeared in North Vietnam together with the report of a long technical interview with the Minister of Health in North Vietnam, Dr Pham Ngoc Thach. The WHO document now issued is at pains to emphasize the incomplete character of this information, "which is not open to the usual methods of confirmation". The most recent figures in the reports refer to 1964, and the WHO report says that until official statistics are available, "the health situation in North Vietnam must remain somewhat obscure". On the basis of the comparison which it has been possible to carry out, however, it does seem that North Vietnam is less seriously afflicted by disease than the south, and that it is taking measures to prevent the situation getting out of hand.

In South Vietnam, epidemic plague, cholera and an upsurge of syphilis and gonorrhoea are distinctive features; other communicable diseases, especially tuberculosis, together with the lack of adequate sanitation and water supply, are, however, major public health problems. Plague infection has been reported to be widespread among rodents and fleas at certain ports and airports, and cases of the disease have now been recognized in 27 of the 47 provinces This situation is worsened by the large-scale movements of the civilian and military population, the prevailing environmental and sanitary conditions, the large number of vermin with their accompanying ectoparasites, the disruption of control programmes and the prevalence of antibiotic-resistant strains of *Pasteurella pestis*

The numbers of cases of typhoid and paratyphoid are also alarming, a total of 934 people were infected in 1966 Similarly, cases of cholera have risen from none in 1957 to 835 in 1966 and cases of encephalitis from 10 in 1957 to 330 in 1966 The incidence of diphtheria, poliomyelitis, malaria and rabies is also increasing at an alarming rate Reliable figures of the incidence of venereal diseases are not easy to obtain, and the problem is complicated by the presence and movement of military personnel and others living apart from their families and homes It is certain, however, that an increase of gonorrhoea reaching epidemic proportions has occurred among adolescents and young adults

To judge from the figures available, the situation in North Vietnam is surprisingly mild by comparison Plague, cholera and other dengue-like diseases seem to be absent Poliomyelitis has been virtually eradicated and tuberculosis has been substantially cut back typhoid fever is also on the way to extinction The reasons for these differences are not clear, but, as the report emphasizes, the information available for North Vietnam is not open to the usual methods of confirmation Bacterial dysentery seems to be one of the most widespread diseases and all venereal diseases are present Leprosy is also endemic

What measures are being taken to combat these large-scale infections? According to the report, vaccination and immunization are being used, but once again North Vietnam seems to have taken the lead As many as 13 million people in the north have been inoculated against smallpox and up to 18 million against cholera These compare with the figures of more than one million and more than two million respectively in the south In 1967, there were 1,184 hospitals and other establishments in South Vietnam for the care of in-patients and out-patients, and twenty-six operating theatres in provincial hospitals have been built or redesigned the number of medical personnel of the Ministry of Health has increased over the years between 1962 and 1967 Long-range planning in South Vietnam is not easy, the report maintains, because of the unsettled state of the country It has been suggested that an expert group should be appointed to study the situation and establish a national health plan, and a short-term consultant was provided by the WHO during the early months of 1967 to review the existing situation and to advise on national health planning A comprehensive study of health problems and services has also been made by a United States appraisal team which made recommendations for long-term developments

Although these findings may seem more encouraging for the North Vietnamese, the nutritional standard in the north is lower than in the south Calorie intake in the south seems to be uniformly adequate, and protein intake is ample, but there are a number of deficiencies, particularly of thiamine, riboflavine and vitamin *A* In the north, on the other hand, the inadequacy of the diet is evident, especially in children the diet is monotonous, and consists mainly of foods rich in carbohydrate and poor in protein and animal fats

Parliament in Britain

Decimal Currency

LORD BESWICK said that the Government had no intention of postponing the change to a decimal currency system Decimalization was now well advanced two out of the preparatory five years were over and much capital had already been expended Because of the real economic benefits which would accrue it was the view of the Government that it was in the best interests of the country as a whole to proceed with decimalization as planned The change was expected to be of real help to the expansion of the British export trade (Oral answer, House of Lords, January 31)

Committees of Inquiry

THE Secretary of State for Defence, Mr D Healey, gave the membership of six committees of inquiry for the Ministry of Defence appointed since October 1964 The committees and their chairmen are Sub-Committee on Research and Development for Anti-submarine Warfare (Dr J C Kendrew), Space Review Committee (Professor H Bondi), Armoured Warfare Sub-Committee (Professor J L M Morrison), Conventional Armaments Working Party (Professor B H Flowers), Personnel and Anti-Personnel Research Working Party (Professor P L Krohn), and Working Party on Materials Research (Professor A H Cottrell) The Defence Research Committee was responsible for keeping the defence research programme under review to ensure that it was geared to defence needs within the resources available Agreements with universities to carry out longer term research in aid of defence operational analysis were made wherever appropriate and two studies, involving exploratory work of interest to the study of land warfare, were at present being undertaken at Newcastle and Nottingham Universities The Defence Operational Analysis Establishment also had frequent, but less formal, contacts with university faculties Arrangements had been concluded with certain universities to create an additional post in an existing faculty to specialize in the defence aspects of its discipline Five such appointments had so far been made, at Aberdeen, Edinburgh, London (King's College), Oxford (All Souls College) and at Southampton, and two further appointments were under consideration (Written answer, January 31)

Research Establishments

THE Minister of Technology, Mr Anthony Wedgwood Benn, stated that the programmes of the Ministry's research establishments were kept under review by committees on which industry was strongly represented The ministry was encouraging the establishments to take on more work for industry on a repayment basis In defence and civil aviation, joint research programmes had been set up with the Society of British Aerospace Companies, aimed at rationalizing the location and finding of the work At the Royal Radar Establishment, an Industrial Applications Unit had been set up to act as a focal point for the application in industry of the results of the establishment's defence research Generally, the policy was that the programmes of the establishments should be closely related to the needs of industry and drawn up in collaboration with them (Written answer, January 31)

American Science Marks Time

THE budget introduced to the United States Congress by President Johnson on January 31 will have brought very little pleasure to the scientific community in the United States Scientists may, however, comfort themselves with the knowledge that the needs of the war in Vietnam have similarly curtailed the growth of expenditure in several other fields, and particularly in the development of federal programmes for the improvement of cities and of education of all kinds Everybody may, however, be pleased to see that the way in which the United States Administration has sought to draw a clear distinction between its estimates of what will be spent in the fiscal year beginning on July 1 (fiscal year 1969) and its request to Congress for new authorization, which frequently covers expenditure further ahead than the end of fiscal year 1969, has made this year's budget much easier to follow than its predecessors

The continuing decline in the expenditure of the National Aeronautics and Space Administration is perhaps the most conspicuous feature of the budget, although perhaps only because it is easily identifiable The less explicit changes of the pattern of expenditure within the budget of the Department of Defense may have a more serious effect on what happens in American universities in the year ahead For what it is worth, however, expenditure on space research and technology in 1969 is expected to work out at $4,573 million, compared with $4,803 million in the present financial year and $5,423 million in fiscal year 1967

The decline of the space budget is made possible by the fact that the Apollo programme is over the peak of its expenditure At the same time, it seems plain that NASA is being allowed to keep alive most of its hopes for programmes which will follow on Apollo even if some of these have been postponed or watered down Thus President Johnson announced in his budget message that the production of the Saturn V rocket will continue but at a reduced rate, that the development of the nuclear rocket engine will continue but that the engine will be smaller than the one first planned two years ago and that work will begin on the development of a spacecraft to put into orbit about Mars in 1973 using the Titan III rocket and not Saturn V as a launcher

In practice, expenditure on the Apollo programme as such will fall to $2,571 million in 1969 compared with $3,587 million in 1967, but there are plans to spend $422 million in the year ahead on other ventures with men put into orbits about the Earth, the President drew particular attention to a scheme for using spent rocket vehicles for various unspecified scientific purposes The growth of these schemes has, however, been accompanied by a decline in the expenditure of NASA on purely scientific work, which will account for $498 million in 1969 compared with $624 million in 1967 The development of communications satellites will take a little more The fact that NASA's expenditure on aircraft research will increase from $113 million to $120 million is partly accounted for by the beginnings of a programme to use aircraft as means of surveying natural resources from above so as to decide whether satellites would eventually be able to take over work of this kind

The Department of Defense will increase its total expenditure on scientific research, partly because of the development of anti-ballistic missile systems, strategic surveillance and what is called the "next generation of tactical aircraft" At the same time, the Department of Defense is spending more on its manned orbital laboratory, chiefly because of its concern for surveillance In effect, the advance research budget will increase from $4,600 million in 1968 to $5,100 million in 1969 It is not possible to tell from the budget how these changes will affect the amounts of money which the Department of Defense and its various subdepartments have to spend on research in American universities, but the experience of the past year seems to have been that the increasing pressure on the defence budget has curtailed the amounts of money which the services are able to spend on academic projects

The expenditure of the Atomic Energy Commission will increase along with that of the Department of Defense, and chiefly for the same reasons—the development of the anti-ballistic missile systems Within its budget, however, the AEC is planning to increase its expenditure on the development of civilian nuclear power stations from $163 million to $258 million, chiefly because of its concern to speed the development of fast reactors The basic research budget increased from $421 million to $555 million, but this is chiefly explained by the beginning of work on the Weston accelerator, which will eventually cost $250 million

For the rest, the budgets of the agencies chiefly concerned with research and development remain more or less static—few of them have increased sufficiently to make up for increasing costs (The Office of Saline Water is perhaps an exception, with a budget increased from $31 million to $41 million) At the same time, the National Bureau of Standards is receiving less as direct subvention from the Federal Government—$39 million in 1969 compared with $41 8 million in the current year A comparatively modest increase of $32 million in the billion dollar budget of the National Institutes of Health conceals an emphasis on the work of the National Heart Institute among others One cheerful feature of the budget is a plan to spend some $85 million in the coming year on the provision of buildings for medical schools and $197 million on curriculum development, staff and expansion programmes and financial assistance to medical students in medical schools

Thus the budget for the National Science Foundation will in 1969 be $480 million (compared with $456 million in the current year and $412 million in 1967) What the foundation has to spend on basic research is hardly changed ($230 million) Its institutional science programme, chiefly concerned with the development of centres of excellence, increased from $72 million to $78 million Science education will continue to take a quarter of the foundation's budget

The direct consequences of the budget for universities will be felt most seriously in the diminished ability of the Federal Government to pay for facilities on university campuses A year ago, grants towards university buildings were deliberately increased by 50 per cent to just over $300 million, now they are reduced to $230 million almost the same as in 1967

NEWS AND VIEWS

Cellular Interdependence

THE coexistence within the same animal of groups of cells with different genetic constitutions has attracted increasing attention in recent years. Immunologists, for example, recognize that the existence of mosaic individuals may help to define the conditions under which genetically different populations of cells may share the same physiological frame. Embryologists seek to know more about the circumstances under which mosaic individuals develop. The coexistence of genetically different groups of cells is then turning out to be important in the recognition of inheritable genetic defects. Now there is also the suggestion that the processes of ageing, which are known to be statistically associated with an increasing incidence of genetic abnormalities of some kinds in human reproduction, may also be linked with the increased appearance of genetic abnormalities among the body cells of living individuals. [The alternative suggestion by Dr James German, on page 516 of this issue, of the processes underlying the increasing incidence of mongolism with increasing maternal age, should not at this stage be regarded as more than what he says it is—an interesting hypothesis which deserves fuller study.] In one way and another, there has recently been a surge of interest in the coexistence of genetically different groups of cells, and it is plainly of the greatest importance to know just what factors determine the equilibrium between two such populations.

Basic biological studies by Dr D. T. Hughes of the Chester Beatty Research Institute (page 518) have demonstrated that co-operation as well as competition between cells affects the evolution of cell populations. Although interaction by cross-feeding—a situation in which cells produce substances into the culture medium which other cells take up and make use of—has previously been described in bacterial and fungal cultures, it has generally been regarded as a nuisance to be avoided, because it complicates the genetic analysis of micro-organisms. Dr Hughes, however, has shown the biological significance of interaction between cells; it is a genetically important factor in evolution, superimposed on the action of straightforward environmental selection—"survival of the fittest". The discovery of a new kind of balanced genetic polymorphism was made as a result of analysis of cell populations as a whole, carried out to determine whether there was any basis for co-operative interaction between cells. The resulting biological concept envisages a balance of cell types in which the frequencies of types of chromosomes among the cells contribute to a balance similar to that which exists in a normal cell. The situation seems to be that the balance of nature at the level of the population obeys the same laws as at the lower level of organization, within a single normal cell. Previous work on genetic polymorphism has not demonstrated this kind of balance because populations have not been considered as a whole. On the contrary, earlier work has been concerned with the frequency of characters in single cells or single organisms within a population.

It remains to be seen whether this type of polymorphism can be demonstrated *in vivo* in populations of organisms living in restricted environments analogous to the culture bottle—perhaps populations of mammals or plants living in geographically restricted environments such as islands would be interesting to investigate. There is, however, a possibility that fuller use could now be made of cultured cells as a model system for the study of evolution.

This new concept will also be of more immediate practical importance in clinical medicine. It should be important in the understanding of the development of mosaics and chimaeras, and in the study of tumour cell populations and their therapy—the idea of the pseudo-stemline may help to explain some of the difficulty encountered in killing off tumour cells.

Geomagnetic Dynamo Energy

from a Geophysics Correspondent

IT seems now generally accepted that the main geomagnetic field is produced by "dynamo" action—a magnetohydrodynamic (MHD) interaction in the Earth's liquid, conducting core which produces an essentially dipolar field whose axis coincides approximately with the rotational axis. Less firmly established is the source of the energy required to produce the fluid motions. It is fair to say that majority opinion favours thermal convection as the power source for the dynamo, although Malkus (*J. Geophys. Res.*, **68**, 2871; 1963) concluded that the driving force may well be the Earth's rotational energy operating through a differential precessional torque between mantle and core.

Stacey (*Earth Plan. Sci. Letters*, **3**, 204; 1967) has now presented a revised estimate for the electrical resistivity of the Earth's core which suggests that Malkus's theory is the more appropriate. Any MHD theory requires the core to possess a "magnetic Reynolds number" considerably greater than unity. After making the usual numerical substitutions for core scale size, magnetic diffusivity and velocity of core motions, this means that the resistivity should be substantially smaller than 4×10^7 e.m.u. Hitherto, estimates of core resistivity, based on extrapolation of the resistivity of iron to core temperatures and pressures, have been at least a factor of one hundred smaller than this figure, thereby satisfying the condition for an MHD interaction. Stacey points out, however, that such estimates have failed to take into account the effect of impurity elements which, if present in the core, will alloy with the iron.

A core containing ten per cent nickel alloying with the iron will possess a resistivity three times greater than that of pure iron Of greater importance, however, are the lighter elements which must be present to account for the fact that the core density is lower than that of iron If the core contains 15 per cent silicon, as suggested by Ringwood (*Geochim Cosmochim. Acta*, **15**, 257, 1969), its resistivity will be ten times higher than that of pure iron If it contains dissolved MgO, as suggested by Alder (*J Geophys Res* , **71**, 4973, 1966), the increase in resistivity will be even greater These considerations indicate a core resistivity of at least 3×10^6 emu (a factor of ten higher than previous estimates), but presumably less than 2×10^7 emu above which dynamo action is precluded

The magnetic Reynolds number is thus reduced to about ten, which, though still greater than unity, is sufficiently low to call in question the validity of a convective dynamo theory on the grounds that the energy requirements would be difficult to satisfy Stacey thus suggests that "we must prefer a mechanism which has sufficient [energy] in hand to operate at low efficiency", and so turns to the alternative Malkus theory. In further evidence he cites the virtual absence of field harmonics of wavelength less than 1,500 km at core level, which also indicates a lower magnetic Reynolds number, and he produces calculations to show that tidal and mantle dissipations are insufficient to account for the use of all the Earth's rotational energy. The excess energy might well be used to drive the geomagnetic dynamo.

If it is too soon to decide between the various dynamo theories, this is not only because of the difficulty of assigning accurate numerical values to core parameters on the basis of surface laboratory experience but also because of the absence of substantial laboratory data This is clearly a case where accurate measurements of the electrical resistivities of liquid iron alloys are required to narrow the range within which the core resistivity may lie In short, it is yet another example of the importance of laboratory physics to Earth science

Thermal Analysis Standards

Dr H G McAdie of the Ontario Research Foundation, Sheridan Park, Ontario, chairman of the Committee on Standardization of the International Conference on Thermal Analysis, has written as follows

Thermal methods of analysis, particularly differential thermal analysis (DTA) and thermogravimetry (TG), have achieved major importance as techniques for the study of materials [Differential thermal analysis is a technique in which the cooling rate of the material studied is compared directly with that of a standard If one junction of a thermocouple is immersed in the standard and the other in the material, any change in the cooling rate, such as might be caused by a phase change, is readily detected Thermogravimetry is a technique in which the weight of a specimen is recorded as it is heated] Such dynamic temperature methods often impose stringent requirements different from those associated with their isothermal counterparts, particularly in relation to proper experimental design based on a thorough understanding of the underlying physical principles, and to the full reporting of all pertinent experimental detail in order that the published record may be fully understood and critically evaluated

In view of the lack of essential information existing today in much of the thermal analysis literature, the Committee on Standardization of the International Conference on Thermal Analysis, established in 1965, has recently published (H G McAdie, *Anal Chem*; 543, 1967) a series of nine general and three specific recommendations concerning the necessary experimental detail which should accompany any report of information obtained from DTA or TG These recommendations are also being published in French, German, Japanese and Russian, as well as in a number of other languages, and the editors of all relevant major scientific journals are being invited to consider and adopt them so that the quality and value of the thermal analysis literature may be improved significantly Further recommendations will be issued periodically, as the methodology develops, including extensions to the newer techniques combining DTA and TG with effluent gas studies, measurement of electrical resistance and the like

The Committee on Standardization, which represents the major international areas of greatest activity in thermal analysis, is also undertaking an extensive programme to evaluate standard substances for use in the calibration of the temperature axis in DTA Subsequent programmes are planned to provide materials suitable for calibration of the enthalpy axis in DTA and the temperature axis in TG Such standard substances will not only allow the calibration of a given instrument and provide reliable systems with which to evaluate sensitivity, resolution and reproducibility, but will permit the direct intercomparison of data obtained in different laboratories involving dissimilar instrumentation

Reports of progress toward these objectives will be made to the Second International Conference on Thermal Analysis to be held in Worcester, Mass , August 18–24, 1968

Viruses and Chromosome Breakage

from our Cytogenetics Correspondent

It has been known for a number of years that viruses, including those able to induce tumours, are able to cause chromosome breakage in the cells they have infected There is a suggestion that the breaks are found preferentially at chromosomal regions that are among the last to replicate Further evidence for this has now been provided by Huang and by Kato Huang (*Chromosoma*, **23**, 162, 1967) treated cells of the rodent *Mastomys*, cultured *in vitro*, with herpes simplex virus, adenovirus-12, the mutagens 5-bromodeoxyuracil (BUdR), 2-aminopurine, and the carcinogen 7,12-dimethylbenz(*a*)anthracene All these agents caused chromosome breakage, but some chromosomes had fewer and some had more breaks than expected if breakage of chromosome regions was at random The long arm of the X-chromosome was especially sensitive and this region is known to replicate its DNA later than the remainder of the DNA The Y-chromosome is also a late replicator, yet it seems only sensitive to BUdR The Y is difficult to identify with certainty, however, so its sensitivity may have been underestimated A similar study by Kato (*Hereditas*, **58**, 221, 1967), using cultured Chinese hamster cells infected with Rous sarcoma virus, showed a high incidence of breakage located at the secondary constrictions—

regions also thought to be late in replicating their DNA Kato also recorded the sites where spontaneous breakage occurred and it turned out that these sites are the same as those broken by the virus

But what do these results indicate about the nature of the chromosome at the points of breakage or about the properties of the virus ? It seems likely that there is some qualitative difference in the structure of the chromosome that predisposes certain regions to high breakage frequencies Some years ago Hsu proposed that regions broken by certain mutagens were rich in particular DNA bases, but since then knowledge of this problem has not been much extended The position in the infected cell from which the virus directs the induction of a chromosome break is not even known with certainty Observations by Halkka (*Hereditas*, **58**, 248 and 251, 1967) may be relevant—he found that in the testes of the cricket *Acheta* infected by a rickettsia-like organism, the microbe was to be observed lying on the nuclear envelope and even to be lying on the chromosomes themselves Infection of these meiotic cells caused many lesions in the chromosomes similar to those induced by viruses If a parallel can be drawn, it is that the damage done by viruses to chromosomes may well be caused by their intimate association with the chromosome at certain preferred points, thereby impairing chromosome replication Unfortunately, viruses have not yet been located within the structure of chromosomes from higher organisms

Steroids and ATPase

from our Medical Biochemistry Correspondent

THE maintenance of the correct concentrations of sodium and potassium ions in mammalian systems is literally of vital importance. When sodium and potassium ions are moved across cell membranes against a concentration gradient, adenosine triphosphate (ATP) is split to provide the energy for the process The enzyme responsible is thought to be an ATPase which is dependent on the presence of sodium and potassium ions for its activity Bader, Post and Bond have now made preparations of this enzyme from eleven different species and six different tissues, and have shown that they are remarkably similar (*Biochim Biophys Acta*, **150**, 41, 1968) They all required the presence of sodium ions to form a ^{32}P-labelled protein from ^{32}P-labelled ATP, and dephosphorylation of the protein was always stimulated by the presence of potassium ions Although the specific activity of the preparations varied greatly, the ratio of ATPase activity to phosphoenzyme and ATPase to acyl phosphatase was always approximately the same The ^{32}P-labelled preparations were digested with pepsin or pronase and the resulting ^{32}P-labelled peptides were separated by electrophoresis The peptides all behaved identically on electrophoresis and on treatment with hydroxylamine, suggesting that the enzyme structure which becomes phosphorylated is the same in preparations of the enzyme from all these different sources

The corticosteroids produced by the adrenal gland are the hormones which regulate salt and water metabolism, and it has now been shown that the activity of the sodium and potassium activated ATPase in rat kidney varies with the plasma concentration of adrenal steroids (P L Jørgensen, *Biochim Biophys Acta*, **151**, 212, 1968) After removal of the adrenals, the activity of the ouabain-sensitive sodium and potassium activated ATPase activity of rat kidney decreased along with the sodium/potassium ratio of the plasma A sodium-rich diet delayed the appearance of both decreases The decrease in activity appeared to be due to a decrease in the amount of enzyme, as the enzyme kinetics were the same for preparations from normal and adrenalectomized animals The attachment of the enzyme to the membranes of the microsomes may be altered, as the decrease in activity was most marked when activity was measured in the presence of deoxycholate and ethylene diamine tetra-acetic acid

If adrenal steroids affect this ATPase, and these enzymes are all very similar, it is hardly surprising that adrenal steroids can affect the salt metabolism of tissues other than the kidney In a recent investigation (R Shields, J B Miles and C Gilbertson, *Brit Med J* , (i), 93, 1968) a patient with an adrenal tumour secreted four to five times as much potassium into the colon as did eight normal controls, but 3 months after operation his potassium loss was normal Since half the daily loss of potassium from this patient was in the faeces, urinary estimations alone could seriously underestimate the potassium loss in patients treated with adrenal steroids, with serious consequences

Ribosomal Proteins

from our Cell Biology Correspondent

THE chemical heterogeneity of ribosomal protein has now been established beyond question Tissières and his colleagues, for example (*Proc US Nat Acad Sci* , **57**, 1294, 1967), recently isolated and partially purified a number of proteins from *E coli* ribosomes. Given the great chemical heterogeneity of ribosomal proteins, there is every reason to expect that these proteins are functionally heterogeneous The problem then is that of defining the functions of the individual proteins and how their individual properties relate to the overall function of the ribosome In the current *Proc US Nat Acad Sci* (**58**, 2430, 1967), Traub, Hosokawa, Craven and Nomura report an analysis of the function of five basic proteins isolated from the 30*S* sub-unit of *E coli* ribosomes

Their approach was to prepare a series of ribosome derivatives, each deficient in a specific ribosomal protein and to compare the properties of their derivatives with those of normal ribosomes Having first dissociated 70*S* ribosomes into 30*S* and 50*S* sub-units, Traub *et al* further dissociated the 30*S* sub-unit into a 23*S* core which has none of the properties of a 30*S* sub-unit, and free protein—the so-called split proteins They then separated the split proteins into acidic and basic protein fractions Particles reconstituted from 23*S* cores and the acidic split proteins have none of the known properties of 30*S* sub-units, whereas particles reconstituted from cores and the basic split proteins are partially active The basic split proteins are essential for the 30*S* functions, whereas the acidic split proteins, though stimulatory, are not essential

Following up this result, Traub *et al* resolved the basic split protein into five component proteins with quite distinct amino-acid compositions To determine the function of each of these five proteins, they reconstituted 30*S* sub-units from 23*S* cores, all the acidic split proteins and four of the five basic split proteins, and then asked which 30*S* sub-unit functions the five classes of deficient particles have. Apparently two of the proteins (B_3 and B_5) and possibly a third (B_1) are essential for both amino-acid incorporation and binding of specific amino-acyl-*t*RNA. Protein B_4 is not required for these functions, but may be involved in chain initiation, and the remaining protein, B_2, has a stimulatory effect on amino-acid incorporation, but no definite conclusion about its function was reached. These preliminary experiments have certainly established that the specific activity of ribosomal protein can be assayed, and it should be possible now to unambiguously define the function of many ribosomal proteins.

Part of the function of ribosomal proteins must be to provide the two specific *t*RNA binding sites, one for peptidyl-*t*RNA and initiator *t*RNA and the other for amino-acyl-*t*RNA. Nomura *et al* (see *Nature*, **216**, 638, 1967) provided strong evidence that the peptidyl and initiator site was at the 30*S* sub-unit and that the amino-acyl site is formed by the joining of 30*S* and 50*S* sub-units. These experiments were done with *f*2 phage RNA as messenger, but the ideal messengers for such experiments are the synthetic ribopolynucleotides poly-UG and poly-AUG. Both poly-AUG and poly-UG contain codons which specify formyl methionine at chain initiation and methionine and valine and cysteine internally. Khorana's group has synthesized these polymers, and Ghosh and Khorana (*Proc US Nat. Acad Sci*, **58**, 2455, 1967) have repeated Nomura's experiments using them as messengers. Their experiments prove that two *t*RNA binding sites exist, and, furthermore, they fully confirm Nomura's scheme for the initiation and synthesis of polypeptide chains.

How Repressor Molecules Function

by
MARK S BRETSCHER
MRC Laboratory of Molecular Biology,
Cambridge

During the past year two repressor molecules were detected, purified and some of their properties determined. The results confirm much of the theory, proposed by Jacob and Monod in 1961, for the control of gene function.

In 1961, Jacob and Monod[1] proposed their celebrated theory of how the activity of genes could be controlled. This theory, which is outlined below, followed from observations on the lactose operon of *Escherichia coli*. The lactose, or *lac*, operon is a cluster of three adjacent genes, which code for three enzymes. In order for *E coli* to utilize the disaccharide lactose, two of these enzymes are required. When *E coli* is grown in the absence of lactose, the three enzymes of the *lac* operon are present in only very small amounts; if lactose is added to the growth medium, the rate of synthesis of these three enzymes is increased about one thousand-fold and the operon is said to be "induced". Thus *E coli* is able to switch the *lac* operon on when needed: otherwise it is switched off.

The three enzymes of the *lac* operon, β-galactosidase, a membrane-bound permease and thiogalactoside transacetylase, are coded by the *z*, *y* and *a* genes, respectively (see Fig 1). Both β-galactosidase and the permease are needed to metabolize β-galactosides, such as lactose; the function of thiogalactoside transacetylase is not known. The sugar which induces the *lac* operon is called an inducer. It has been shown that the induction of the *lac* operon does not depend on the utilization of the inducer. Thus isopropylthiogalactoside (IPTG), a compound not found in nature, will act as an inducer of the *lac* operon although it cannot be metabolized. Inducers, such as IPTG, which trick the cell in this way, are called gratuitous inducers.

Close to the *lac* operon is the *i* gene which, as originally proposed by Jacob and Monod, is the structural gene for the repressor. They suggested that the repressor molecule could bind to a postulated operator site, or *o* region, adjacent to the *z* gene, thereby switching off or "repressing" the *z*, *y* and *a* genes. This repression of the *lac* operon was presumed to occur at the level of messenger RNA transcription, that is, binding of the repressor to the operator was presumed to prevent synthesis of messenger RNA from any of the three genes of the operon. In the presence of a β-galactoside inducer, it was proposed that the repressor would bind to the inducer and thereby be removed from the operator site in the DNA. According to the model, the repressor, once removed from the operator site, has no further effect on the *lac* operon; the messenger RNA corresponding to the operon is synthesized and is subsequently translated on the cytoplasmic ribosomes. The net result, of course, is the synthesis of the three enzymes.

Much of the evidence for this model has come from the study of bacterial mutants whose control of the synthesis of the *lac* enzymes is altered. These mutants fall into two classes which map genetically either in the *i* gene or the *o* region. The mutants of the *i* gene can be further subdivided into i^s and i^- mutants. i^s are super-repressed—they cannot be induced to form the *lac* enzymes even in the presence of inducer. i^- mutants, by contrast, synthesize maximal amounts of the *lac* enzymes even in the

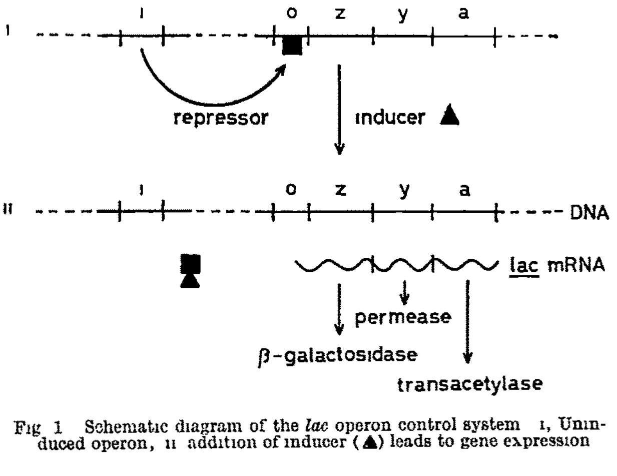


Fig 1 Schematic diagram of the *lac* operon control system. i, Uninduced operon, ii addition of inducer (▲) leads to gene expression

absence of inducer. In terms of the Jacob–Monod theory, these two types of *i* gene mutations reflect the dual nature of the *lac* repressor. In i^s mutants, the repressor is presumed to have lost all its affinity for β-galactosides and the *lac* operon is thus permanently repressed. The repressor in an i^- mutant, on the other hand, is assumed to have lost its affinity for the operator region so that, even in the absence of inducer, full synthesis of the *lac* enzymes occurs. Mutants in which the lesion maps in the *o* region are called o^c mutants and appear to be deletions of part or all of the *o* region—that is, part of the DNA corresponding to the *o* region is missing. These mutants, like i^- mutants, make large or maximal amounts of the *lac* enzymes even in the absence of inducer. According to the Jacob and Monod model, the alterations of the *o* region occurring in such mutants have rendered the *o* region incapable of binding repressor, so that synthesis of the enzymes is uncontrolled.

Evidence that the repressor is a diffusible molecule came from a study of partial diploid strains of *E. coli* which possess two complete *lac* operons. In a strain possessing an i^- gene and an i^+ gene, the i^+ gene is dominant. That is, the introduction of an i^+ gene into a cell containing an i^- gene results in the loss of the lack of control which pre-existed in the i^- cell. The *i* gene product is an active repressor and can function in a *trans* (as well as the usual *cis*) fashion and is therefore a diffusible molecule.

The predicted properties of the *lac* repressor are therefore that it can bind both to an inducer molecule and to the operator region, but it cannot bind to both at once. The *i* gene is the structural gene for the repressor.

More recently genetic evidence has shown that the product of the *i* gene is a protein molecule. This was demonstrated by the isolation of suppressible amber mutations in the *i* gene. Amber mutations have their deleterious effects during protein synthesis, so it follows that any gene in which amber mutants can be generated codes for a protein molecule.

Apart from the *lac* operon, several other control systems have been studied. The *lac* operon is induced when a small molecule, a β-galactoside, is added to the growth medium. There are other operons which are repressed when a small molecule is present. For example when *E. coli* is grown in the presence of the amino-acid histidine, the enzymes of the *his* operon which are responsible for the biosynthesis of histidine are repressed; in the absence of histidine, the *his* operon is induced. This form of control is readily fitted into the scheme for the *lac* operon presented here if the repressor for the histidine operon can only bind to its operator in the presence of histidine. In the absence of histidine, the repressor is removed from the operator, allowing messenger RNA to be copied from the *his* operon.

Of particular interest here is the control of the genes of the bacterial virus, λ. When this phage infects *E. coli*, one of two events can occur. The phage can multiply in the host cell, which it eventually kills, producing a few hundred progeny phage. The alternative event is that the λ phage enters a dormant state in the host cell. In this case the λ chromosome becomes physically integrated with the host chromosome—that is, the DNA is inserted into the *E. coli* DNA. In this latter state the phage is described as a prophage; most of the λ genes are not expressed. This repression of the λ prophage genes is mediated by a λ repressor molecule which is genetically coded by the c_1 gene of the prophage. This control system is formally similar to that of the *lac* operon. The c_1 gene codes for the λ repressor and is analogous to the *lac i* gene. The λ repressor represses the expression of the λ genome except for the c_1 gene; hence *E. coli* carrying λ as a prophage has λ repressor molecules in its cytoplasm. The effect of these repressors is two-fold. They prevent the λ genes in the prophage from being expressed. They also prevent any λ genome which might be injected into the bacterium by an infecting λ phage from expressing itself. Thus the λ prophage repressors confer immunity on the host cell from outside infection by other λ phage. The λ repressor is the "immunity substance".

During the past year, the principal advance in this field came with the isolation of the *lac* repressor by Gilbert and Muller-Hill[2,3], and the λ phage repressor by Ptashne[4,5], all at Harvard University. Some of the properties of these two repressor molecules were also determined; a summary of their findings constitutes the remainder of this review.

The *lac* repressor was detected by its ability to bind the gratuitous inducer, IPTG. Because only about ten *lac* repressor molecules exist in *E. coli* per chromosome, giving a concentration of about 10^{-8} molar in a solid pack of *E. coli* cells, and since the binding constant of the repressor for IPTG is about 6×10^{-6} molar, detection of the normal *lac* repressor would be almost impossible. Gilbert and Muller-Hill therefore isolated a "tight-binding" mutant of the repressor which they estimated had approximately a ten-fold increased affinity for the inducer, IPTG. This *lac* repressor was detected by placing a cell extract of this mutant *E. coli* inside a dialysis sack and leaving it to equilibrate with a dilute solution of radioactive IPTG. They found that slightly more radioactive IPTG was found inside the sack than outside it, thus demonstrating that a component of the extract could bind this inducer. Using this binding as an assay for the repressor, they purified the repressor and showed that the observed binding was freely reversible and that the molecule responsible for binding the IPTG is a protein with a molecular weight of about 200,000. In order to prove that this protein which binds the labelled inducer is indeed the repressor, defined as the product of the *i* gene, these authors showed that an extract of an i^s mutant (which had been purified in the same way as their "tight-binding" mutant extracts) was incapable of concentrating IPTG inside the dialysis sack.

More recently, Gilbert and Muller-Hill have purified the *lac* repressor from *E. coli* cells which had been grown on radioactive sulphate to label the proteins. Using this partially purified labelled repressor, they sought to test directly the model for control of the *lac* operon as proposed by Jacob and Monod. First, they showed that some of the radioactive protein in their purified *lac* repressor preparation became bound to pure DNA which contains the operator region of the *lac* operon. The DNA used for this experiment was isolated from a hybrid bacteriophage which carries the *lac* operon in its chromosome. The labelled repressor preparation was mixed with this DNA and was then analysed by centrifugation through a sucrose gradient. DNA molecules sediment much faster than the smaller protein molecules, and were found to carry a small proportion of the labelled protein. This labelled protein bound to the DNA carrying the *lac* operator region is the *lac* repressor. This was proved by the inability of DNA from a similar bacteriophage, but which had a defective operator region (o^c), to bind the repressor as tightly. Furthermore, when the binding of this repressor to DNA carrying an intact *lac* operator region was carried out in the presence of the inducer IPTG, no repressor was found bound to the DNA.

These experiments beautifully illustrate the mechanism of control of the *lac* operon. The repressor binds the inducer, but cannot then bind to the operator region. In the absence of inducer, the repressor binds to the operator region. How is this recognition achieved? For several years it has been imagined that the repressor is a nucleoprotein, possibly having a piece of RNA associated with it which could recognize the operator region by base-pairing. Gilbert and Muller-Hill have shown that pre-incubating this labelled repressor with ribonuclease (which would destroy a putative RNA molecule) does not affect the binding of the repressor to the operator region. Thus the repressor itself must recognize the operator DNA sequence. Furthermore, they also showed that the repressor will not bind to denatured DNA. The repressor therefore recognizes the operator, which is a unique segment of double-stranded helical DNA; just how long is this region is unknown, but at least twelve base-pairs in the DNA would probably be required in order for it to be a unique sequence in the *E coli* chromosome

The experiments performed by Ptashne on the λ repressor were all carried out by labelling the repressor with radioactive amino-acids This was necessary because there is no known assay for the λ repressor equivalent to the equilibrium dialysis against labelled IPTG which was used to detect the *lac* repressor Ptashne's aim was to infect *E coli* carrying a λ prophage with λ phages in the presence of a radioactive amino-acid, by choosing suitable conditions he hoped that a high proportion of the label incorporated into protein would be in λ repressor molecules To achieve this, Ptashne eliminated most of the protein synthesis of the host cells by strongly irradiating them with ultraviolet light to inactivate their DNA before infecting them with λ phages Second, as mentioned earlier, the λ repressor molecules present in *E coli* carrying the λ prophage will prevent expression of the infecting λ phage genes, except for their c_1 genes In order to obtain large numbers of λ repressors per cell, Ptashne infected each host cell with about thirty λ phages Because there are initially not enough λ repressors per cell to cope with thirty infecting phages, however, all the experiments were carried out with λ phages which also have a lesion in their *N* genes, this, in an unknown way, prevents most of the λ genes from functioning, but does not affect the activity of the c_1 gene

The experiment consisted, then, of heavily irradiating *E coli* containing a λ prophage with ultraviolet light and then infecting two parallel cultures of these cells either with the wild-type λ (with a defective *N* gene) or with λ phages having a defective c_1 gene (as well as a defective *N* gene) One culture was then labelled with ^{14}C-leucine, the other with ^{3}H-leucine After about an hour of growth the two cultures were mixed and an extract of the mixture prepared The mixture of proteins thus obtained was fractionated on a DEAE ion exchange column and the fractions monitored for both the ^{14}C and the ^{3}H labels The ratio of isotopes was found to be essentially constant except for a major peak corresponding to the *E coli* cells infected with the wild-type λ; this peak was absent from the cells infected with λ having a defective c_1 gene This protein peak was thus presumed to be the product of the c_1 gene Several experiments prove that this is the case, the most elegant of them made use of a mutant of the c_1 gene which was known to give the λ repressor a greater efficiency as a repressor This mutant, called ind$^-$, was shown to synthesize a repressor whose chromatographic properties on the DEAE column were different from those of the wild-type repressor

Thus, a mutation in the c_1 gene changes the properties of this protein peak, this positively identifies this protein as the product of the c_1 gene and hence as the λ repressor or immunity substance Ptashne showed that this repressor appeared homogeneous by electrophoresis on a polyacrylamide gel Its molecular weight, as judged by its rate of sedimentation in a sucrose gradient, is about 30,000 This is a sixth of the estimated size of the *lac* repressor More recently, Ptashne has shown that this labelled repressor can bind to λ DNA This was demonstrated by mixing λ DNA with labelled repressor and then analysing the mixture on a sucrose gradient Labelled repressor was found bound to the DNA As a control experiment, he showed that the repressor does not bind to the DNA of a hybrid λ phage which contains most of the λ genes but has a different immunity (and hence λ operator) from wild-type λ Ptashne also showed that the λ repressor cannot bind to denatured λ DNA

In conclusion, these experiments have served to prove several of the principal points of the Jacob–Monod theory of the control of gene expression In both cases, the repressor molecule has been shown to be a protein molecule capable of binding with great specificity to a site on the DNA It does not seem that either repressor contains a nucleic acid moiety, furthermore, the repressors bind only to helical DNA and not to denatured DNA In the case of the *lac* repressor, inducer binds to the repressor, thereby preventing the latter from binding to the operator region of the *lac* operon The next step in this exciting elucidation of the biochemistry of control mechanisms will probably be to show that when the repressor binds to DNA, it switches off the genes of the operon it controls by preventing the RNA polymerase from copying the operon into a messenger RNA

Large-scale Density Inhomogeneities in the Universe

by
M. J. REES
D. W. SCIAMA
Department of Applied Mathematics and Theoretical Physics,
and
Institute of Theoretical Astronomy,
University of Cambridge

There may be large scale density inhomogeneities (such as quasar clusters) in the universe, and their effect on the angular distribution of the cosmic black-body radiation could potentially be observable.

OUR aim is to discuss the possibility that observations of the angular distribution of quasars and of the cosmic black-body radiation may in the future yield important information about large-scale inhomogeneities of density in the universe There is already fragmentary evidence to suggest that this possibility may be fruitful It therefore seems desirable to clarify the theoretical situation in order to call the attention of observers to these possibilities and to prepare the way for the interpretation of the results they may obtain

The first suggestion that quasars with large red-shift may not be distributed randomly in the sky was made by Strittmatter, Faulkner and Walmesley[1], who drew attention to two prominent groupings, one in the direction of the North Galactic Pole and the other in the South Galactic hemisphere. If these groupings are real and if the quasars are at cosmological distances, the most likely explanation[2] is that quasars are clustered on a scale much larger than any previously studied scale of irregularities in the universe. This suggestion links up with the question of the angular distribution of the cosmic black-body radiation because, as was first pointed out by Sachs and Wolfe[3], large-scale irregularities would influence the temperature of radiation which passes through them. A possible example has been discovered recently by Wilkinson and Partridge[4] and has encouraged us to carry out further calculations of the effects involved. We shall give a simplified description of our results here, reserving for a separate publication by one of us (M. J. R.) a more detailed account of the calculations.

Scale of Possible Quasar Clusters

The angular size of a possible quasar cluster is a non-trivial question because, at large red-shifts, important model-dependent relativistic effects come into play. If a cluster expands at the same rate as the background universe, and if its present diameter is d_0, then at earlier times corresponding to a red-shift z, the diameter would be

$$d = \frac{d_0}{1+z}$$

If d_0 is much smaller than the present "radius" of the universe c/H_0 (where H_0 is the present Hubble constant), the angular diameter at various red-shifts can readily be calculated in terms of d_0H_0/c. We shall restrict our attention to Robertson–Walker models with zero cosmical constant which can be characterized by the density parameter

$$\sigma_0 = \frac{4\pi}{3} G\rho_0 c^2/H_0^2$$

in which ρ_0 is the present mean density. If the cosmical constant is zero, σ_0 is equal to the deceleration parameter q_0. Numerical values for the angular diameter are given in Table 1 for three values of σ_0.

Table 1 ANGULAR SIZE OF A FREELY EXPANDING CLUSTER AS A FUNCTION OF ITS RED-SHIFT z

z	Angular diameter (units of d_0H_0/c)		
	$\sigma_0=\frac{1}{2}$	$\sigma=1/10$	$\sigma_0=1/100$
0.5	2.72	2.41	2.40
1	1.71	1.34	1.33
1.5	1.36	0.99	0.96
2	1.18	0.80	0.75
3	1.00	0.59	0.53
∞	0.50	0.10	0.01

The case $\sigma_0=\frac{1}{2}$ corresponds to the Einstein–de Sitter model, the case $\sigma_0=1/100$ to roughly the lowest permitted value for the mean density ($\rho_0\sim 4\times 10^{-31}$ g cm^{-3} if $H_0\sim 100$ km sec^{-1} Mpc^{-1}) and $\sigma_0=1/10$ to an intermediate case.

We note that for a given present size d_0, the smallest angular scale occurs at the largest red-shift (though this would not be the case in closed models with $\sigma_0>\frac{1}{2}$). In fact, a cluster would not expand at the same rate as the rest of the universe: if it had developed from a perturbation of small-amplitude, it would be separating out, so that the angular diameter would depend somewhat less steeply on z than in Table 1. Deviations from free expansion would be more important in a higher-density universe.

We now ask what linear size to expect for a quasar cluster. According to Sandage and Luyten[5], there are about 0.4 quasars (quasi-stellar radio sources and quasi-stellar galaxies combined) per square degree down to $B=18^{\mathrm{m}}$. Thus the minimum detectable angular scale of a cluster would be a few degrees. In fact only about 200 QSOs have so far been discovered, and these would be too sparsely distributed over the sky to reveal any clustering on an angular scale less than 10 or 20 degrees. But from Table 1, a freely expanding cluster with a red-shift of, say, 1.5 and subtending an angle of about 20 degrees, would have linear dimensions ~ 750 Mpc at the present epoch in an Einstein–de Sitter universe. This is an appreciable fraction of the "radius" of the universe ($\sim 3{,}000$ Mpc), and so the question arises: is it reasonable to consider that irregularities may exist on such a large scale? This is a difficult question because we do not yet understand the origin of the known small-scale irregularities in the universe. It may, however, be helpful to consider what is known, or reasonably conjectured, about these small irregularities. This information is summarized, in very round figures, in Table 2, where we have assumed that $\rho_0\sim 10^{-30}$ g cm^{-3}.

Table 2 OBSERVED CLUSTERING IN THE UNIVERSE

Scale	Object	Density contrast $\left(\frac{\delta\varrho_0}{\varrho_0}\right)$
30 Kpc	Galaxy	10^6
1 Mpc	Galaxy cluster	10^3
30 Mpc	Supercluster	10
1,000 Mpc	?	?

It does not seem out of the question that on a scale $\sim 1{,}000$ Mpc, there should be quasar clusters in which $\delta\rho_0/\rho_0$ is of the order of unity. If the rate of formation of quasars depends on some power of the ambient density as seems to be the case with stars where the power involved is ~ 2 (ref. 6), or if the lifetime or brightness of quasars is enhanced by the higher density, the concentration of quasars would help to delineate the density distribution and quasar clustering might be detectable.

Further insight into the possibility that there may be large-scale irregularities in the universe can be gained from a consideration of the behaviour of perturbations with various scales during the expansion of a "hot big bang" universe. During the earliest stages of such a universe, the energy density of the radiation would exceed the rest-energy of the matter, and the matter and radiation would be strongly coupled together. Taking the present temperature of the primeval black-body radiation to be $\sim 3°$ K and H_0 to be ~ 100 km sec^{-1} Mpc^{-1} (so that $\rho_0\sim 4\times 10^{-29}\sigma_0$ g cm^{-3}) the radiation-dominated phase continues until the temperature falls to $T_c\sim 8\times 10^4\sigma_0°$ K (at a time t_c, say). During this period the Jeans length is essentially the radius of the observable universe. Another critical stage in the expansion occurs when $T=T_d\sim 3{,}000°$ K (at time t_d). At this time the matter almost completely recombines and subsequently becomes almost transparent to radiation, at least until it is reheated. In a low density universe, there is a third important time, t_e, corresponding to a red-shift $(1+z)\sim 1/2\sigma_0$. Before t_e the universe behaves like the Einstein–de Sitter model, but afterwards the deceleration parameter decreases towards zero.

We define $r(t)$ to be the present length-scale of a perturbation which would roughly fill the observable universe at time t. Then

$$r(t_c)\sim 4\times 10^6\sigma_0^{-1}\ \mathrm{pc}$$

and

$$r(t_d)\sim\begin{cases}2\times 10^7\sigma_0^{-\frac{1}{2}}\ \mathrm{pc} & (\sigma_0\gtrsim\frac{1}{25})\\ 10^8\ \mathrm{pc} & (\sigma_0\lesssim\frac{1}{25})\end{cases}$$

For $t>t_e$, $r(t)$ is roughly the radius of the presently observable universe.

We shall discuss only "adiabatic" perturbations in which the densities of matter and radiation are both perturbed so that the entropy per baryon is the same as in the unperturbed state. We also confine ourselves to perturbations which, in the absence of pressure gradients, would be of the "relatively increasing" kind. We can visualize these as regions of the universe which start expanding with a kinetic energy different from their surroundings, in contrast to "relatively decreasing" perturbations, which can be thought of as starting to expand at a slightly different time from the rest of the universe, but with the same energy.

Perturbations of any given scale r exceeded the horizon size at sufficiently early times. At those times they evolved independently of the rest of the universe. If $r < r(t_c)$, the perturbations start to interact with other parts of the universe during the radiation-dominated phase ($t < t_c$), and will then oscillate until t_d. Any density or—more important—velocity perturbations which survive at $t > t_d$ will initiate the growth of condensations, for the matter can then condense unimpeded by the radiation and the gas pressure is about 10^{-8} times the radiation pressure or less. Adiabatic expansion causes the oscillations to diminish in amplitude between t_c and t_d. Furthermore, there will be significant damping due to radiative viscosity during this period (for the mean free path of the radiation, though much less than the horizon distance, is by no means negligibly small). Even while the gas is still ionized, adiabatic perturbations with r up to a few Mpc would have been damped out[7] during the recombination phase, all scales up to $r(t_c)$ would suffer appreciable damping. Initial perturbations with $r > r(t_c)$, on the other hand, never undergo an oscillatory phase nor are they subject to radiative damping.

If the initial amplitudes of these large-scale perturbations are sufficiently large (and always if $\sigma_0 \geqslant \frac{1}{2}$), they will eventually develop into bound systems. However, if $\sigma_0 < \frac{1}{2}$, smaller-amplitude perturbations may still have positive energy. They will undergo relative growth, but eventually self-gravitation will become negligible even within the perturbation and the density contrast will subsequently remain constant during the free expansion. If the density within an unbound cluster eventually exceeds the background density by a factor x, say, the separating out will be almost completed by a time $t \sim x\, t_e$.

The initial spectrum of irregularities in the universe is a mysterious question, and it is, of course, possible that perturbations on scales $\gg r_c$ and r_d have much smaller initial amplitudes than the smaller scale amplitudes which presumably developed into galaxies, galaxy clusters and superclusters. There is no *a priori* reason to rule them out, however, and we have seen that they would in fact grow faster than smaller-scale perturbations of similar initial amplitudes.

In the remainder of this article we discuss the types of observation which may, in the future, determine whether very large scale irregularities do actually exist in the universe.

Observational Evidence

The following lines of evidence are at present relevant the angular distribution of (*a*) quasars, (*b*) the black-body radiation and (*c*) the radio source counts.

(*a*) *Quasars*. The angular distribution of the 103 quasars with red-shifts known to us does at least suggest that there may be clustering at large red-shifts on an angular scale ~ 20 degrees. The number of quasars is still too small for us to be able to decide whether the effect is significant, especially because of the effects of selection.

(*b*) *Black-body radiation*. We turn next to the interesting question of the isotropy of the primeval black-body radiation. This problem was discussed by Sachs and Wolfe[3], who calculated the amplitude of the temperature fluctuations which would be caused by a distribution of perturbations (with small $\delta\rho_0/\rho_0$, but arbitrarily large length-scale) in an Einstein–de Sitter universe. In that analysis, the temperature anisotropies can be attributed to the perturbation in which we are situated and to perturbations so distant that the radiation underwent its last scattering when passing through them. We are here, however, especially interested in the effects on the black-body radiation of particular irregularities with $z \sim 1$–3 which may be delineated by observed concentrations of quasars. The radiation would have undergone its last scattering long before passing through such an irregularity, so that Sachs and Wolfe's work is not directly relevant. Moreover, the amplitude of the density fluctuations will not be small—in fact, no quasar clustering would be evident unless $\delta\rho_0/\rho_0 \gtrsim 1$—and we wish to discuss open universes with $\sigma_0 < \frac{1}{2}$ as well as the Einstein–de Sitter model. We shall therefore describe a somewhat different type of analysis, the aim of which will be to determine the order of magnitude and sign of the temperature variations induced by the gravitational field of a single perturbation.

In a homogeneous isotropic universe with negligible pressure, the material within a co-moving sphere would expand in exactly the same way if the remainder of the universe were removed. If $\sigma_0 < \frac{1}{2}$, the sphere would have positive energy and its radius R (taking the usual Schwarzschild radial co-ordinate) is related to the proper time t of an observer moving together with the boundary by

$$\left.\begin{aligned} R &= 2\left(M\,\frac{(1-v_\infty^2)}{v_\infty^2}\right)\sinh^2 y \\ t &= M\left(\frac{(1-v_\infty^2)}{v_\infty^2}\right)^{3/2}(\sinh 2y - 2y) \end{aligned}\right\} \qquad (1)$$

(c and $G = 1$) where v_∞ is the asymptotic velocity, which will be a function of σ_0 and the gravitational mass M. The radius R is simply proportional to the scale factor of the universe.

The remainder of the universe would expand in identical fashion if the matter within the co-moving spherical boundary were replaced by any other spherically symmetrical distribution of matter with the same value of M. The type of perturbation which we shall consider will be one in which the matter within a co-moving sphere is replaced by a uniform sphere of the same mass but lower kinetic energy. If the total energy is still positive, the expansion of the sphere will be given by equation (1) with v_∞ replaced by $v_\infty (< v_\infty)$. Initially the universe would be almost uniform, but a spherical condensation would gradually separate out, the density contrast finally attaining a value $x \sim (v_\infty/v_\infty)^3$. The expansion of the spherical perturbation would mimic a universe with a different radius of curvature.

Expressions analogous to equation (1) can be written down for bound clusters which eventually contract and for clusters separating out of an Einstein–de Sitter universe.

A perturbation of this type is illustrated schematically in Fig. 1*a*. Any inhomogeneous universe must contain clumps of enhanced density surrounded by regions of density less than average. Such a universe can be simulated by a "swiss cheese" model in which spherical perturbations like that shown in Fig. 1*a* are distributed through space. The perturbations would exert no gravitational influence on one another, but would each develop as though they were embedded in an otherwise uniform and isotropic universe. The absence of any significant 12 h or 24 h anisotropy in the radiation temperature[8] confirms that the overall expansion of the universe is in fact accurately isotropic.

Before we discuss how the black-body temperature would be perturbed by an irregularity of the type shown in Fig. 1*a*, it will be helpful to consider the frequency shift induced by passage through a uniform expanding sphere, centre O, surrounded by empty space. Suppose that light is emitted at a point X (at rest relative to O and far outside the sphere), passes through O, and is received at a distant point Y. The presence of the sphere would increase the time light takes to travel from X to Y

The passage of such a light ray is traced schematically in Fig. 2. At first sight one might think that, if X and Y are equidistant from O, there would be no frequency shift between the two points. Though this would be true if the sphere were not expanding, the expansion in fact causes a blue-shift. This effect can best be understood by imagining that monochromatic light is being emitted from X. The time delay caused by the sphere diminishes as the sphere expands, so that each wave-crest is subject to a shorter delay than its predecessors. The crests are thus received at Y with a frequency higher than the emitted frequency (see Fig. 2). An alternative interpretation may make this effect clearer: the light falls towards O down a steep potential gradient but, because the sphere is expanding as the light goes through, it climbs up against a more gradual potential gradient and achieves a net gain of energy from the gravitational field.

Suppose that a particular ray enters the sphere at a point A at time t_A and emerges from the other side at t_B (see Fig. 2). Since the sphere can be regarded as part of a homogeneous universe, the ratio of the wavelengths observed by co-moving observers at A and B is

$$1 + z = \frac{R(t_B)}{R(t_A)} \qquad (2)$$

This red-shift can be interpreted as the sum of three contributions: (i) the *blue*-shift already discussed, due to the expansion; (ii) a straightforward Doppler red-shift, due to the fact that A and B are both receding from O when the radiation passes through them; and (iii) a gravitational red-shift

$$(1-2M/R(t_B))^{1/2}/(1-2M/R(t_A))^{1/2}$$

When the sphere is part of a homogeneous universe, these three contributions combine to give the same net red-shift as equation (2). When, however, we come to consider inhomogeneities, this is no longer true and it is then helpful to treat the three contributions separately.

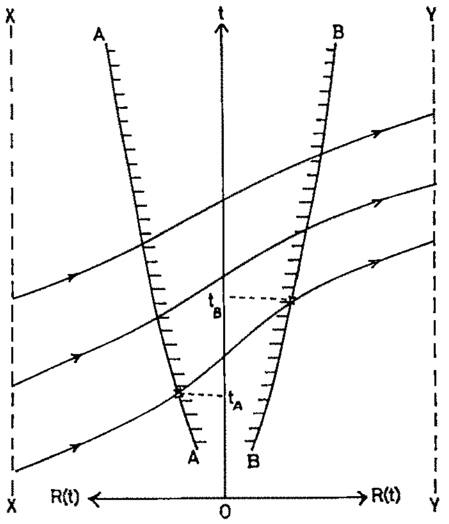

Fig. 2. Diagram tracing the paths of light rays through an expanding sphere surrounded by empty space. These rays experience a time delay which decreases as the sphere expands, so they would be observed at Y blue-shifted relative to X.

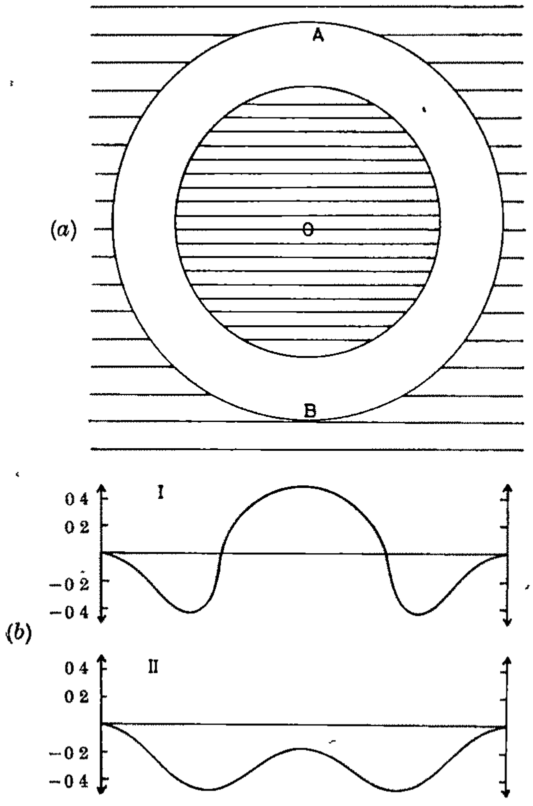

Fig. 1. *a*, Illustration of the type of spherically symmetric perturbation discussed in this article. *b*, Temperature profiles across a cluster with ~3 times the background density. $\Delta T/T$ is expressed in units of GMv/c^2R, where v and R are the velocity and radius of the unperturbed boundary. The profiles are drawn for (I) an undecelerated background universe and (II) an Einstein–de Sitter universe.

The accurate calculation of the temperature perturbations is rather complex, even for spherically symmetric density irregularities. We shall present here a simplified treatment which is strictly valid only for irregularities very much smaller than the observable universe. It should, however, be good enough to give the sign and magnitude of the temperature variations due to clusters of the size in which we are interested (up to ~1/4 of the radius of the universe). This simple treatment may also elucidate more clearly the physical interpretation of the effects involved.

We assume that the expanding sphere had radius R' and expansion velocity v', when the radiation which we now receive passed through it, whereas if the same mass M were expanding with the rest of the universe, its radius and velocity would be R and v respectively. If the cluster were small compared with the horizon size, these quantities would change only by small amounts during the passage of the radiation. We can also assume $R' \gg M$, and v and $v' \ll 1$. v' and R' cannot be specified independently, because they are related through equation (1). Suppose that there are no other irregularities along the line of sight through O, and that the black-body radiation is not scattered after passing the point A.

The changing gravitational field within the sphere of radius R' will (through effect (i)) contribute a blue-shift $2Mv'/R'$. If, however, the matter were smoothed out there would be a blue-shift $2Mv/R$. If the cluster were separating out from the background $v'/R' < v/R$, so that effect (i) makes a *negative* contribution to $\Delta T/T$.

The cluster will create a deeper potential well at O than would be present if the material were smoothed out, and its existence will thus increase the time radiation takes to get from A to B. This extra time delay tends to increase the black-body temperature (an effect which we shall call (iv)) for the following reason. The radiation reaching B at t_B must have passed A at the instant t'_A ($<t_A$). The temperature at A, being proportional to R^{-1}, would have been higher at this earlier time. The extra time delay amounts to

$$\sim 2M \log (R/R') \qquad (3)$$

so

$$R(t_A) - R(t'_A) \sim 2Mv \log (R/R') \qquad (4)$$

and the consequent fractional temperature increase due to (iv) is

$$\frac{2Mv}{R} \log (R/R') \qquad (5)$$

The alterations in (ii) and (iii) caused by the extra time delay expression (3) make negative contributions to $\Delta T/T$ which, however, are $\sim M/R$ times smaller, and so can be neglected In this approximation, the net temperature change caused by the irregularity (and attributable solely to effects (i) and (iv)) is therefore

$$\frac{\Delta T}{T} \sim 2M \left\{ \frac{v'}{R'} - \frac{v}{R} \left(1 - \log \left(\frac{R}{R'} \right) \right) \right\} \qquad (6)$$

In a very low density universe where the cluster has already separated out completely, $v'/R' \sim v/R$ so that expression (6) would then be positive The same is true for any unbound cluster in a universe with $\sigma_0 < \frac{1}{2}$ If the density contrast is small, and $v' = v - \delta v$, $R' = R - \delta R$, the magnitude of $\Delta T/T$ is proportional to $\delta R/R$ If we apply equation (6) to an Einstein–de Sitter universe, we find that $\Delta T/T$ is negative because v'/R' is then smaller than v/R by a sufficient amount to make (i) more important than (iv). In this case, however, the effect is proportional to $(\delta R/R)^2$ when the density contrast is small This is because $\delta v/v = 2\delta R/R$, so that the first order terms in equation (6) cancel out This is in agreement with Sachs and Wolfe's first-order analysis, according to which a perturbation of this type in an Einstein–de Sitter universe would have zero effect on the black-body temperature

One can similarly calculate $\Delta T/T$ for radiation which is intercepted by a cluster but does not pass through the centre and thus determine the expected temperature profile across a cluster For irregularities of the type considered here, it is found that $\Delta T/T$ is negative near the edge for all values of σ_0, though (as we have seen) it becomes positive at the centre for a cluster of positive energy The profiles are shown in Fig 2b for a cluster with ~ 3 times the mean density, for models with two different values of σ_0 The exact profiles should not be taken too seriously, because they obviously depend on the detailed density distribution across the irregularity It is, however, interesting that even the simple type of cluster considered here can cause a ΔT of either sign

Radiation which does not pass through O will suffer a small angular deflexion due to the gravitational field of the cluster Liouville's theorem[9] ensures that the magnitude of this deflexion is exactly what is required to produce the black-body radiation intensity appropriate to the perturbed temperature

A cluster with $d_0 \sim 750$ Mpc, contrast density ~ 3, and $z \sim 1\ 5$ in an Einstein–de Sitter universe would give rise to a decrease of $\sim 0\ 3$ per cent in the radiation temperature in the direction of its centre and $\sim 0\ 9$ per cent somewhat away from the centre The angular extent of the profile would be ~ 20 degrees A similar cluster in a low-density universe with $\sigma_0 \sim 1/10$ would give rise to a decrease in temperature of $\sim 0\ 2$ per cent near the edge, but a comparable increase at the centre Wilkinson and Partridge[4] observed a possible decrease in temperature of $\sim 0\ 5$ per cent in the direction $R\ A \sim 2$ h, $\delta \sim -8°$ If this is attributable to a quasar cluster in the same general direction, we conclude that either the universe has roughly the Einstein–de Sitter density or, if the density is lower, the strip of sky scanned by Wilkinson and Partridge did not pass through the centre of the cluster

We must next try to establish that the temperature anisotropies attributable to clusters with $z \sim 1$–3 will not be swamped by the effects of more distant clusters[10] Since seven-eighths of the material within the particle horizon of an Einstein–de Sitter universe (and an even larger fraction in the case of a lower density universe) lies at $z > 3$, it would be unreasonable to suppose that no such clusters exist Formula (6) can be applied provided that the radiation has not been scattered since entering these clusters, and provided also that they are then smaller than the observable universe We find that if $(1+z) \lesssim 1/\sigma_0 x$, where x is the terminal value of the density contrast, $|\Delta T/T|$ increases in proportion to $(1+z)$, for larger z, it decreases roughly as $(1+z)^{-\frac{1}{2}}$ for the universe, then approximates to an Einstein–de Sitter model These very distant clusters do not therefore pose a problem except in a very low density universe ($\sigma_0 \lesssim 1/20$)

Consider now the clusters which lie across the surface where the last scattering occurred (at a red-shift $z \sim z_s$) If $(1+z_s) \lesssim 1/x\sigma_0$, the effect will be of the same order as formula (6) However, if $(1+z_s) \gg 1/x\sigma_0$, we can apply the results of Sachs and Wolfe, since not only would the universe then approximate to an Einstein–de Sitter model at $z \sim z_s$, but $\delta\rho/\rho$ would have been small We find that, if the universe were now filled with clusters of dimensions ~ 750 Mpc, with $\delta\rho_0/\rho_0 \sim 1$ the temperature fluctuations would be ~ 2 per cent This conclusion is independent of σ_0· in a low density universe the clusters separate out more slowly, and the larger value of $\delta\rho/\rho$ at $z \sim z_s$ compensates for the lower mass of each cluster. The angular scale of these irregularities would be $\sim 20\,\sigma_0$ degrees These temperature variations would be ~ 10 times higher than the upper limits permitted by observation[4,11] The value of ~ 2 per cent deduced here may be a very severe overestimate, however, because the clusters need not occupy the whole of space (perhaps no more than 10 per cent) and because Sachs and Wolfe's calculations assumed that the last scattering occurred at a well defined instant whereas the universe would in fact gradually become transparent during a time of the order of the expansion time scale Therefore unless the irregularities are much larger than the horizon size at z_s (that is, unless $z_s \gg 10\sigma_0^{-1}$ if the irregularities have a present scale ~ 750 Mpc), the temperature variations in the Rayleigh–Jeans part of the spectrum due to clusters with $z \sim z_s$ would be smeared out by depth effects

Finally, we must consider whether we ourselves lie within a cluster Unless we were positioned exactly at its centre, our own cluster would produce a 24 h anisotropy in the black-body radiation Though this would be partly due to the gravitational field of the cluster, the main contribution would be essentially a Doppler effect, arising from the fact that the cluster would be expanding more slowly than the overall Hubble velocity we would have a peculiar velocity towards the centre. This effect would be too great to be consistent with the observations unless $\sigma_0 \lesssim 1/100$ In our previous paper[2] we supposed that we were in a cluster, and that σ_0 was indeed very small We have seen, however, that a higher density is permissible without the temperature fluctuations caused by other clusters being too large Since (as we shall see) the isotropy of the radio source counts is harder to reconcile with the existence of clusters if σ_0 is very low, it is perhaps more likely that we are not within a cluster

(c) *Source count isotropy* The radio source counts have provided no evidence for any anisotropy in the distribution of radio sources The permitted limits would appear to be $\lesssim 25$ per cent for sources stronger than 2 flux units at 178 MHz, on scales ~ 20 degrees square[12,13], and $\lesssim 10$ per cent at 0 2 flux units on the same angular scale[13] This figure is based not on direct counts but on a statistical analysis of the measured radio noise Is the hypothesis of large-scale clustering compatible with these data ? We believe so, for the following reasons

(i) Because of the large spread in the intrinsic power of radio sources, a sample chosen at a given flux density will include powerful sources with $z \gtrsim 4$ as well as weak local sources In fact, according to Longair's[15] analysis of the counts, the anisotropy limits at ~ 2 flux units are likely to be more crucial in this regard because it is at this level that the largest contribution comes from very distant sources (It is, however, worth pointing out that interpretations of the source counts, and of magnitude red-shift relations for quasars, would need modification if clustering occurs on the scale envisaged here) Even at ~ 2 flux units, however, sources with $z \sim 1$–2 will be diluted by both nearby and even more remote sources

(ii) The clusters may not have fully separated out at $z \sim 4$ Accordingly we would not expect any large aniso-

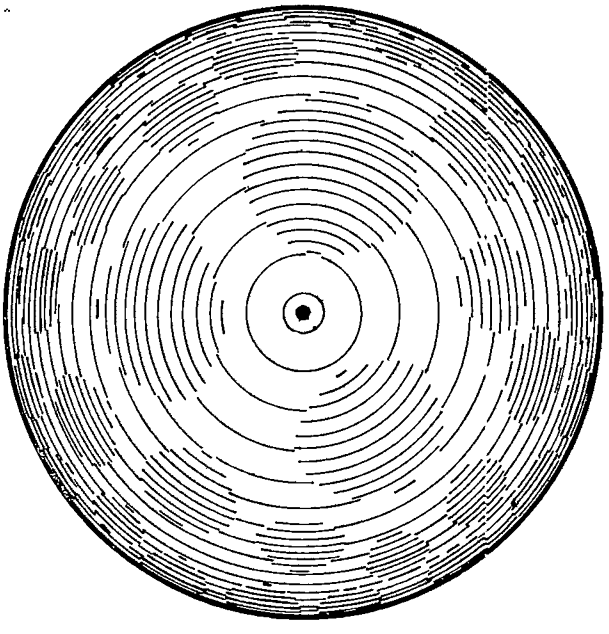

Fig 3 A possible distribution of large scale clusters as seen by an observer at the centre The contrast between clusters and the background would be less marked in the past (though the mean density was then higher) because the clusters would not have fully separated out The shading is meant to illustrate this Very remote objects (for example, radio sources) need not therefore appear anisotropically distributed

tropies in the distribution of the most distant sources The separation would only in fact have been completed by $z \sim 4$ in a very low density universe for which $1/\sigma_0 \tau \gtrsim 5$. We attempt to illustrate this effect in Fig 3 The contrast between the density inside and outside clusters would be less marked at large z, and moreover we would be observing a large number of clusters at these great distances In Fig 3 we are not depicted as being in a cluster ourselves, for the reason already given

Clustering on a scale of $1-2 \times 10^8$ pc could in principle be revealed by a study of the distribution of radio galaxies (and such clustering would be expected theoretically if the even larger quasar clusters exist, except perhaps in a universe with $\sigma_0 \leqslant 1/25$) However, in practice their detection would be difficult because of the number (~ 10) of such clusters which would be expected along a typical line of sight

In this article we have attempted to stress two points The first is that the spectrum of irregularities in the universe may well contain large-scale components of appreciable amplitude The second is that such components, if they exist, may be amenable to systematic observational study by a detailed analysis of the angular distribution of quasars and of the cosmic black-body radiation We would therefore urge that the necessary observational studies be undertaken

Mongolism, Delayed Fertilization and Human Sexual Behaviour

by
JAMES GERMAN
Cornell University Medical College,
New York City,
New York

Decreasing frequency of coitus accompanying advancing age and prolongation of marriage, predisposing to delayed fertilization, may explain the correlation of increased incidence of mongol births with advancing maternal age

MONGOLISM (Down's syndrome)[1] is the developmental consequence of trisomy of chromosome 21 (ref 2) Its cause has remained obscure, but the increased incidence among offspring of mothers more than 35 years old suggests that the chromosomal non-disjunction usually occurs during female rather than male gametogenesis At what stage in oogenesis is such an error particularly likely to occur ?

The maturation of the mammalian egg consists of a first division, which is completed at about the time of release of the primary oocyte from the ovarian follicle, and a second division which begins immediately thereafter The division of the secondary oocyte, however, becomes suspended in metaphase and progresses to completion only after a spermatozoon penetrates it Without such penetration, which usually occurs in the peritoneal cavity[3] or upper portion of a uterine tube, disruption of the alignment of the second division metaphase chromosomes sets in, and generalized cellular deterioration occurs The human secondary oocyte suspended in metaphase has been estimated to be fertilizable for 1 day or less[3-5] In other mammalian species the period of fertilizability varies, it is usually between 6 and 30 h[6] Fertilization toward the end of this brief period often has serious embryological consequences in many species[6-13]

It has been clearly established that delayed fertilization of mammalian eggs may have unfavourable consequences This was recognized in 1934 by Hammond, who detected a decrease in both fertility rate and litter size in rabbits[7] If the oocyte lies unpenetrated in the uterine tube for several hours, its capacity for being fertilized decreases Should it be fertilized late, however, the incidence of abnormal or unsuccessful cleavages, of structurally abnormal embryos, and of embryonic reabsorption or abortion has been observed to increase in several non-human species in experimental conditions[6,8,9] Abnormal eggs containing either one or three pronuclei (including the male) have been observed[6,9], as a result of abstriction of either two or of no secondary polar bodies, that is, both or neither female 1c complements, at the second maturation telophase Hyperdiploid, hypodiploid and mosaic embryos have been found in increased numbers after delayed fertilization[13,14], and cytogenetic examination of the oocyte which has remained unfertilized in the tube for several hours has shown scattering of chromosomes from the metaphase plate of the arrested second maturation spindle[11,13] The various errors in division observed experimentally may be attributed to a disturbance of chromosomal segregation of the maturing egg existing outside the ovary and suspended in metaphase II a few hours too long before a spermatozoon becomes available to penetrate it and cause syngamy There is no evidence that metaphase II of oogenesis is less vulnerable in man than in other mammals examined so far Blandau and Young proposed that delayed fertilization might be a cause of early abortion in the human female[8] Edwards[15] more recently emphasized the desirability of beginning embryonic development "with a pair of fresh gametes"

Human Fertilization

In many mammals, coitus-induced ovulation or periods of oestrus are among the mechanisms ensuring fusion of fresh gametes only In the human female, however, ovulation is not coincident with as clearly demarcated a period of heat Delayed fertilization in human females seems therefore to be a possibility if coitus occurs only sporadically or if it occurs regularly but relatively infrequently—that is, at intervals greater than that of the fertilizing potential of spermatozoa, which is perhaps 48 h[4,5] With regular coitus at intervals shorter than this, it would become relatively impossible for an egg to loiter in the upper tube for long before being met by one of the continuously present, capacitated spermatozoa A decline in the regular frequency with which spermatozoa are deposited in the lower genital tract of a sexually active woman therefore theoretically permits a perilous situation to arise This situation could lead to fertilization of a cell released from its ovarian follicular environment for too long and, as a consequence, errors in chromosomal segregation at the second maturation division could arise. Embryonic triploidy, trisomy, chromosomal mosaicism or other aneuploid states are some of the results possible Many aneuploid embryos would doubtless be aborted or reabsorbed promptly, but a small number would be viable for longer periods, some until birth Those affected by mongolism and the other two autosomal trisomy syndromes would be among those sometimes capable of surviving intrauterine life What might predispose to delayed fertilization in man, and how might it be detected ?

Direct evidence for the occurrence of delayed fertilization in man is difficult to obtain Certain considerations and deductions, however, may lead to meaningful experiments and observations substantiating or contravening it Thus, (*a*) spermatozoa are continually present, and forestall delayed fertilization, only if the intervals between coitus are shorter than the span of time a spermatozoon maintains fertilizing ability, this is possibly two days, (*b*) coital frequency usually decreases with advancing age[16], and, therefore, (*c*) the incidence of abnormal embryos including trisomics might be expected to be greater in older mothers, (*d*) an increased frequency and regularity of coitus in older mothers, however, should reduce theoretically the incidence of abnormal embryos by decreasing the frequency times when the tube contains no spermatozoa As a result the possibilities for delayed fertilization will be reduced Surveys comparing the incidence of mongolism in either old or young groups having sporadic or infrequent coitus with that in similar groups having regular and frequent coitus could provide evidence for or against this expectation It would be useful to make a study of the incidence of mongolism in older mothers recently married, who might as a group be assumed to be sexually more active than mothers of the same ages married for a long time The incidence of mongolism among the offspring of unmarried mothers, who as a group engage in coitus sporadically rather than systematically, could also be determined In addition, careful recording of the frequency of the coitus about the time of conception in both young and old women having mongol children might provide interesting data

Previous Investigation

An assumption that is probably valid is that the mean frequency of marital coitus is negatively correlated with the duration of marriage This assumption is based partly on personal clinical case histories and is also supported by data recorded in the report by Kinsey *et al* [16] According to that report, frequency of marital coitus in women declines at a constant rate from a median of 2 5 times weekly by the age of 25 to 1 3 times by the age of 45 In the age group 41–45 in that survey, 40 per cent of married women had coitus less than 1 0 times weekly, in contrast to 15 per cent in the age group 21–25 The frequency of marital coitus reportedly[16] reaches a maximum in the first 1–2 years of marriage and then steadily decreases Studies correlating age, duration of marriage and coital frequency are not available

The durations of marriage in women before their deliveries of mongols have been investigated as part of a survey aimed at a more complete biological and sociological characterization of women having mongols Because mongolism occurs so much more commonly among offspring of older women, it seemed possible that causative factors might differ in the young and the old The mothers therefore were grouped by age The distribution of the time intervals between marriage and the delivery of a mongol in 201 mothers is shown in Fig 1 About half of the women were 35 or older at the time the mongol was born The mean duration of marriage in the young group was only 4 94 yr, whereas in the older group it was 12 08 yr A unimodal normal or Poisson distribution was found in the older group, there was a striking lack of marriages of short duration Only 17 per cent of mothers past 34, and only 12 per cent of those past 38, had been married 6 yr or less None of the fourteen mothers delivered of a mongol when older than 42 had been married less than 8 yr It is apparent that most women older than 34 delivered of mongols have, in addition to their longevity been married a long time That is, as a group they are not women who are bearing children late because of marriage late in life, as is the case for 30 per cent of all women aged 39–45 being delivered of babies

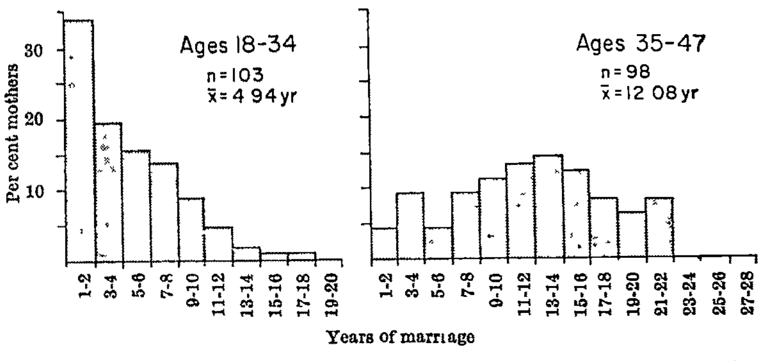

Fig 1 Distributions of durations of marriage before delivery in 201 mothers of mongols, grouped by age This population is composed of (*a*) all married mothers known to have been delivered of mongols at the New York Hospital during a 10 year period (1957–1966), (*b*) the married mothers of all mongols currently institutionalized at the North Jersey Training School and of all mongols who have died in the nursery of that institution whose medical records recorded the date of the mother's marriages

at the New York Hospital (unpublished data for the year 1960) For this second group a bimodal distribution of durations of marriage exists, with a prominent early mode composed of women who married at an advanced age, a mode not present in the older mothers of mongols investigated here

The two distributions in Fig 1 are, as would be expected, very different and are shown partly to emphasize that older women having mongols are different from the younger in ways other than age alone Is mongolism therefore correlated causally with biological old age itself, or is it connected with some superimposed attribute or behavioural pattern characteristic of old age? Consideration of the two distributions in Fig 1 suggests that if delayed fertilization subsequent to infrequent coitus is a cause of mongolism, the circumstances predisposing to it in the young are different from those in the old, the former being a group who in general are much more active sexually because of youth and short duration of marriage This does not necessarily imply, however, that the cause in the young is other than delayed fertilization, although multiple causes certainly might exist Mongolism is very infrequent in young women, common in old Infrequent, unusual and varied circumstances in the young, for example, illness or brief absences from the home of one of the marriage partners, might result in occasional periods of infrequent or sporadic coitus, but these periods could be significant should they coincide with the time an ovum becomes available for fertilization In contrast, the predisposing circumstance—actually a continual threat—for the long-married would be the decline in frequency of coitus usually characteristic of increasing age and adjustment to married life.

Hypothesis drawn from these Data

The following hypothesis is proposed, based on the experimental evidence in animals and on a consideration of man's sexual habits and the known correlation of mongolism and advancing maternal age Mongolism may be the result of delayed fertilization consequent to sporadic or decreased frequency of coitus

I suggest that human disease, genetic in this instance, may sometimes be the result of a disturbance of a natural biological phenomenon resulting from an accepted and seemingly normal pattern of social behaviour rather than from the damaging effects of some inhospitable environment, or from a seemingly spontaneous error of nature The observations suggest a novel medical view of the old mother, an individual in many ways unaltered anatomically, biochemically or as a result of her interaction with some exogenous noxious agent, but different in her sociology and behaviour The hypothesis to explain a cause of sporadic mongolism is attractive not only because it can be tested further but also because it implies that the incidence of the disorder could, in an informed society, be decreased

I thank Dr Melvin S Schwartz of Tufts-New England Medical Center for statistical evidence, Areta Kawal and Margaret German for help in collecting the data, and Dr Fritz Fuchs, Miss Frances Macdonald, Dr Dennis J Buttimore, Dr Irving M. Kurtz and Dr Harry Yolken for assistance Financial aid was given by the New York City Chapter of the National Foundation-March of Dimes

Cytogenetical Polymorphism and Evolution in Mammalian Somatic Cell Populations *in vivo* and *in vitro*

by
D. T. HUGHES
Chester Beatty Research Institute,
Institute of Cancer Research,
Fulham Road,
London

Co-operation as well as competition between cells affects the evolution of cell populations Thus studies on chromosomal variation in relation to age, environment and mechanisms of cytogenetical instability have led to the discovery of a new kind of balanced chromosomal polymorphism.

GENETIC polymorphism has been defined as the occurrence together in the same habitat of two or more discontinuous forms of a species, in such proportions that the rarest of them cannot be maintained merely by recurrent mutation[1] Polymorphic populations can, however, evolve by the action of selection on mutations[2] The study of variation in individual mammalian somatic cells has so far revealed only a few distinct genetical markers, these features include morphological variations in nuclei[3], sex chromatin[4] and chromosomes[5], cytochemical variations in the relative amount of DNA in each nucleus[6] and in each chromosome[7] and the presence or absence of enzymes such as alkaline phosphatase[8] The present communication is primarily concerned with types and frequencies of morphological variations in chromosomes

Essentially the same mechanisms of chromosome mutation (caused by aberrations in chromosome replication and their subsequent segregation at cell division) are responsible for both congenital chromosomal variations in populations of mammals and also within micropopulations of somatic cells in particular tissues Thus similar types of variations in the characteristic pattern of chromosomes in each cell (karyotype) have been found to form the basis of congenital malformations in populations of mammals and also within micropopulations of their somatic cells in particular tissues, indicating the operation of basic mechanisms of chromosome mutation Several genetic and environmental factors are now known to affect the stability of the karyotype and consequent evolution of somatic cells Thus a congenital predisposition for the formation of chromosome anomalies may be inherited, for example, the sticky gene in maize, a recessive human gene associated with breakage of mitotic chromosomes and increased incidence of tumours, a human familial tendency towards chromosome meiotic non-disjunction and congenital malformations[9]. Abnormal individuals caused by such congenital chromosome anomalies seem to have consequently unstable somatic cells, thus Klinefelter's syndrome mosaics and Down's syndrome have a significantly higher incidence of leukaemia, and 31 per cent of Turner's syndrome were reported to have ovarian tumours. There is also a circumstantial association between an increased incidence of spontaneous chromosome anomalies with the ageing of somatic tissues. Three categories of environmental factors affecting karyotype stability can be distinguished: (1) biological, for example, outbreaks of viral infection in North America, Sweden and Japan associated with damage to the chromosomes of somatic cells and an increased incidence of congenital malformations due to chromosomal anomalies, (2) chemical agents such as benzene associated with leukaemia in industry, (3) physical agents, for example, atomic bomb radiation inducing chromosomal congenital malformations, neoplasms and leukaemia in Japan.

Environmental factors in addition to inducing such anomalies also act during the evolution of somatic cell populations. It is now known that, in addition to natural selection of the cellular phenotype in the manner proposed by Darwin, there is an important level of selection of chromosomal mutations within the cell that must be compatible with limiting patterns of chromosome structure[10], thus the types that arise are not entirely the result of natural selection of competing cells. Sometimes a balance of chromosomal types follows selection (*a*) during differentiation of embryos containing two or more chromosome anomalies, resulting in mosaics, (*b*) following exchange of cells across the placenta to give chimaeras, both situations often exemplifying a state of balanced polymorphism. Most information about evolutionary changes in somatic cell populations has, however, been derived from the study of neoplasms[11] and the heteroploid transformation of cultured diploid cells *in vitro*[12].

The present studies were directed at examining the stability of diploid cell populations *in vitro* in standard environmental conditions, to be followed by further experimental studies on the action of one environmental agent at a time on the evolution of somatic cells. As a control, cells from the same species were studied *in vivo* (where this information was not already available) to determine the extent of karyotype stability in normal conditions of animal ageing.

Ageing in Human and Hamster Tissues *in vivo*

Although it had been known for a long time that older mothers produce a higher incidence of Down's syndrome, it was not until 1963 that an increased incidence of chromosome anomalies was also found to be associated with advancing age of normal somatic tissues[13] and this was later confirmed by other studies. No reports are available about the extent of chromosomal anomalies in ageing experimental animals.

In the present study, bone marrow cells were examined in Syrian hamsters ranging in age from 4 weeks to 16 months. No anomalies were detected at 4 weeks, tetraploid cells occurred at a frequency of 0.4 per cent by 11 weeks. Aneuploidy was only found in the oldest of the available animals at 16 months. For example, in a male, chromosome counts in 506 cells showed a mode of 70.4 per cent diploid cells (forty-four chromosomes), with 29.0 per cent aneuploid chromosome numbers (including 12.3 per cent greater than diploid) and 0.6 per cent tetraploid. Karyotype analysis of fifty modal cells showed that 20 per cent were pseudodiploid, as a result of abnormal combinations of chromosome types within the same normal chromosome number (forty-four chromosomes). (The normal male karyotype is conveniently subdivided into five groups according to chromosome size and type: A9, B10, C13, D8, E4 (see Fig. 1).)

Analysis of aneuploid karyotypes of chromosome numbers 43, 45 and 46 showed that they also had abnormal combinations of chromosomes per group within the karyotype, in addition to the expected simple loss or gain of one or two chromosomes. Some aneuploid karyotypes were replicated, indicating the early formation of clones. The most frequent example was a forty-five chromosome karyotype with an extra D group chromosome in ten cells. Thus karyotype instability was found in old, seemingly normal animals, presumably as a result of ageing. These observations provided information on the extent of karyotype variability in somatic cell populations growing in their natural environment, as a "control" for experimental studies *in vitro*.

Ageing and Evolution *in vitro*

If recent work on cultured somatic human cells[14] is of wider validity, as is likely, then other normal mammalian somatic cells will also have a limited lifetime *in vitro*. The number of cell doublings possible *in vitro* was related to the age of human donor tissue. Thus cultured diploid cells could only complete the limited number of cell generations which they had not undergone *in vivo*. Furthermore the frequency of chromosome anomalies was

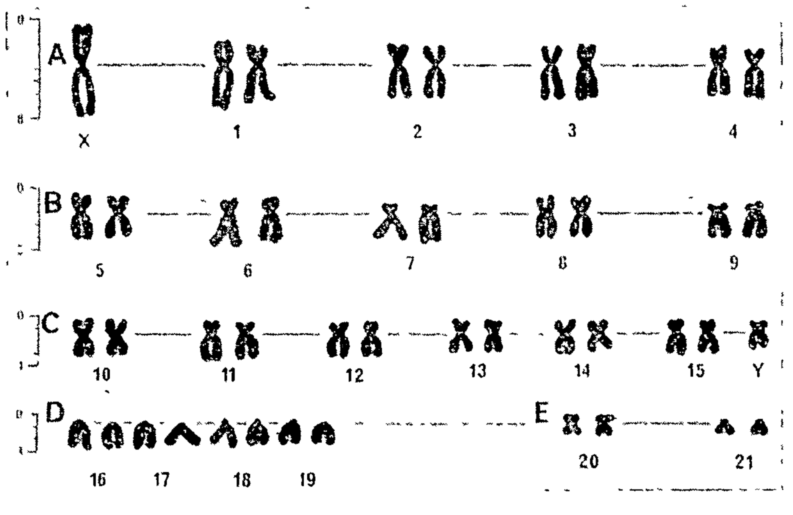

Fig. 1. Karyotype of normal male Syrian hamster (*Microcricetus auratus*)

found to increase as the cells approached the last few generations of their finite lifetime—as was also found in the ageing Syrian hamster bone-marrow in the present study Ageing cultures, however, just before degeneration at the time of onset of increased chromosome anomalies, were sometimes found to undergo malignant transformation. Such transformed cells were found to be capable of indefinite growth *in vitro,* and seemed to be immortal

It was therefore desirable to study the stability of diploid hamster and human cells *in vitro* to obtain further information about the extent of stability of somatic cell populations

Capstick *et al* [15] reported that a diploid cell strain of baby hamster kidney (BHK), established by Macpherson and Stoker, had a 92 per cent diploid mode (forty-four chromosomes) after 110 monolayer transfers and 66 days in suspension culture (a total of 386 cell doublings) Because this length of time was far in excess of a finite lifetime of 50–60 cell generations expected from previous studies, a sample of Capstick's P1 BHK 21/13 was obtained It was aimed to determine by more detailed karyotype analysis if such cells had retained a normal diploid constitution after a long time *in vitro*

The BHK cells were cultivated in suspension in the same way as that described by Capstick *et al* During the logarithmic phase of growth, samples were fixed directly for the study of mitosis and others were fixed after colcemid and hypotonic pretreatment for the study of metaphase chromosomes Two analyses were carried out, 1 month apart, when the cells had grown for 451 and 480 cell generations, respectively A diploid modal chromosomal number was found to be maintained during this time, with a frequency of 29 9 per cent in the first sample followed by 25 0 per cent in the second The later culture (at 480 cell generations) was karyotyped and analysed in detail with the aid of photomicrography The morphological components of the karyotype were grouped into five groups within which certain chromosomes could be identified individually (compare Fig 1) normal chromosomes *X*, 5, 10, 14, 16–19, 20, 21, abnormal chromosomes consisting of a metacentric in group A larger than *X* and another smaller than *X*, also a characteristic submetacentric and a dicentric On this basis it was found that all the diploid cells (at 480 cell generations) were far from normal, they had individually different karyotypes These could be distinguished by (*a*) differences in the combinations of chromosomes per group (A–E) adding up to forty-four chromosomes per cell, or (*b*) even by combinations of the presence or absence of singly identifiable chromosomes alone (see Table 1) In addition, karyotype analysis of aneuploid chromosome numbers (making a total of 100 karyotypes) failed to show two cells with the same karyotype If the sample that was analysed was fully representative of the whole cell population, then the observations indicate not only that the karyotypes were highly unstable but that chromosome mutation probably occurred at most cell divisions to produce different daughter cells

In order to obtain further information concerning the rate of chromosome mutation, the frequency of structural anomalies was determined in 40,000 cells from culture there were 0 2 per cent distinctly abnormal interphases with micronuclei, excessively small or giant nuclei and binucleate cells, 19 2 per cent of anaphases had abnormalities such as bridges and lagging chromosomes, only 4 per cent of 1,000 well spread metaphases (colchicine pretreated) had aberrations of chromosome structure including dicentrics, rings, chromatid interchanges, minute and broken chromosomes The rates of occurrence of structural defects that were observed cannot, it seems, account for the findings of every analysable karyotype in one hundred cells being different

In order to throw further light on this phenomenon, younger diploid cultures were required in order to make serial observations *in vitro* to find out more about karyotype stability in relation to duration in culture Because Burkitt lymphoma cultures recently established by Epstein and Barr were claimed to be diploid, samples of three cell lines, EB1, EB2 and EB3 were obtained for study The culture conditions and cytogenetical studies on chromosomal ploidy levels in the earliest samples have already been described in our previous report in conjunction with the kinetics of these cell lines[16]

D, Chromosomes 16–19, M, group A metacentric chromosomes, smaller than *X* (< *X*) or larger than *X* (> *X*), DC, dicentric, SM, abnormal group A submetacentric chromosome bigger than 1

When first received these cell lines had been in culture for different periods of time, between 5 and 16 months since establishment from tumour biopsies (EB1 and EB2 from females and EB3 from a male)

Fig 2 summarizes the distributions of chromosome numbers in seven samples studied over a period of 28 weeks For convenience, the chromosome numbers are grouped into ploidy levels Euploid chromosome numbers (2*n*, 3*n*, 4*n*) are shown in black and the aneuploid groups of eleven chromosomes are shaded It can be seen that the bimodal distribution in EB1 at 67 weeks changed to a mostly hyperdiploid population at 90 weeks, after it had been grown in a different culture medium (containing calf instead of human serum) This shows the influence of environment superimposed on age Another example of the effect of an *in vitro* environment is provided by EB2, which remained diploid when cultivated in America[17] but had become hypotetraploid by the time that it had been received from its laboratory of origin in the present study The effect of age in a standard environment was then shown by the youngest cell line, EB3

Fig 2 shows that a drastic change in the number of chromosomes occurred after 34 weeks culturing The apparent stability of chromosome numbers before 34 weeks is, however, misleading, because karyotype anomalies were found to occur in cells of the diploid mode as early as 22 weeks This shows the unreliability of chromosome numbers alone as indications of the genetic structure of a cell population

Each karyotype was photographed and analysed for 265 characteristics using a punch card system in order to sort out complicated variations among 350 karyotypes of the lymphoma cultures The analyses have been considered in relation to the age of the cultures (1) The two populations of the youngest cell line EB3, karyotyped in detail, showed that the modal diploid cells were predominantly pseudodiploid at 34 and 50 weeks (61 per cent and 31 per cent, respectively) The frequency of apparently normal karyotypes dropped from 22 2 per cent of the culture at 34 weeks to 9 6 per cent at 50 weeks Altogether, the frequency of any replicated karyo-

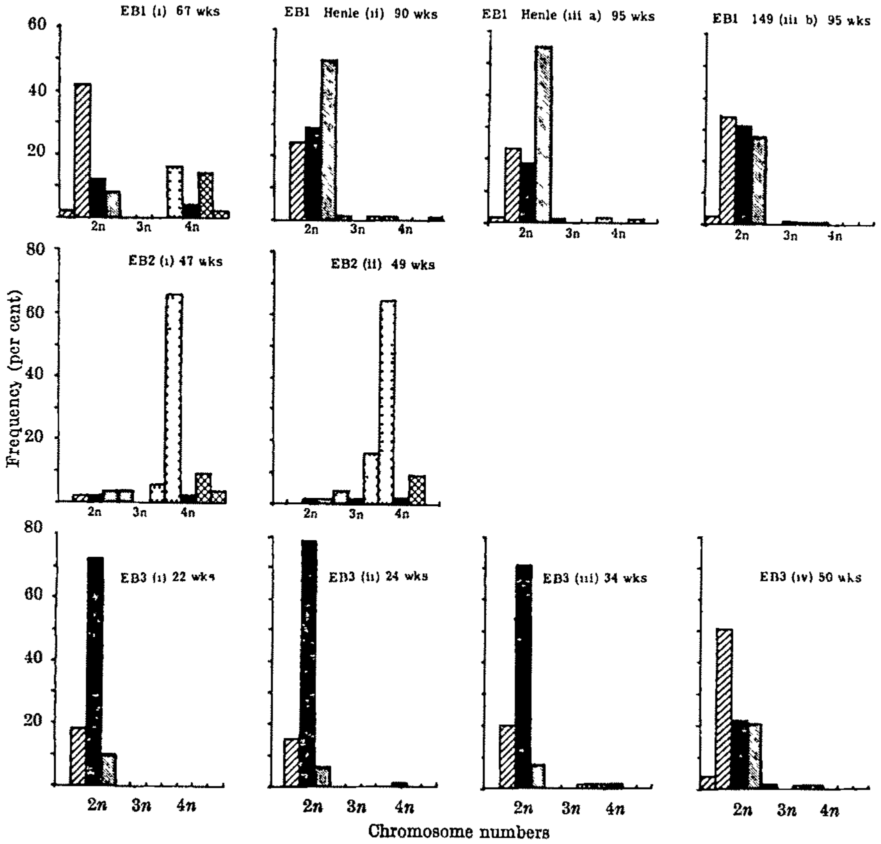

Fig 2 Ploidy level distributions of chromosome numbers in cultures of Burkitt lymphomata

types (euploid and aneuploid) dropped from 22 2 per cent at 34 weeks to 9 6 per cent at 50 weeks (2) The older cell lines EB1 and EB2 were also unstable and had a much reduced frequency of replicated karyotypes 16 5 per cent in EB1 ii at 90 weeks, 18 2 per cent in EB1 iii *a* at 95 weeks, none in EB1 iii *b* at 95 weeks, and also none in the hypotetraploid EB2 ii at 49 weeks Thus in two out of six lymphoma cultures all the cells had different karyotypes, like the situation in the old BHK culture with a seemingly high chromosome mutation rate

Again, like the BHK, the frequency of structurally abnormal chromosomes was too low to account for the observed high frequency of different karyotypes in these lymphoma cultures, ranging from 0 4 per cent of total chromosomes in EB3, to 0 9 per cent in EB1, and 1 4 per cent in the hypotetraploid EB2 (see Table 2) These anomalies included deviations in chromosome size, centromere position, dicentrics, chromatid interchanges and breakage

Mechanism of Karyotype Instability

Cytological mechanisms leading to the formation of abnormalities in chromosomal constitution are still far from being well understood The observations described in this report can, however, be interpreted with the aid of two hypotheses which propose ways in which chromosomes come into close proximity and stick together, followed by non-disjunction at cell division or structural changes such as translocation between chromosomes (1) the nucleolar mechanism[18] was indicated by cytological evidence that nucleolar organizers of different chromosomes tend to form common nucleoli, bringing these chromosomes into close proximity and liable to stickiness, (2) a heterochromatin mechanism[19] was suggested on the basis of autoradiographic evidence and the assumption that late replicating allocyclic segments of autosomal chromosomes consist chiefly of heterochromatin (subsequently demonstrated[20]) Aberrations in the heterochromatin are also known to cause chromosomes to stick together

Neither of these hypotheses alone can explain the observations on hamster and human karyotypes in the present study It is likely that both mechanisms operate in the same cells at the same time Thus deviations from the normal karyotype were not restricted to, nor invariably most frequent in, chromosomes concerned with nucleolar organization in the hamster and human cell populations In the Burkitt lymphoma cultures, karyotype analysis of 350 karyotypes showed a disproportionate gain in group C chromosomes compared with other groups, as was previously found in human tumours[21,22], but the loss deviations were distributed throughout the remainder of the karyotype Groups D and G would have been preferentially affected in each population if the nucleolar mechanism had predominated

The frequency of observed aberrations in chromosome structure was too low in both hamster and human cell populations (as already described) to account for the great diversity of karyotypes Because chromosome interchanges (somatic crossing over) were rare and other obvious structural changes were not frequent enough, the majority of observed anomalous karyotypes were probably caused by deviations in whole chromosomes (without concurrent structural change) This could come about by differential replication of certain chromosomes as found during the evolution of a leukaemia cell population[23] A sequence of gains of particular chromosomes could best be explained by selective endomitotic duplication[24] The evolution of the present cell populations does not seem to follow the same pathway, however, because the karyotypes exhibit both gain or complementary loss of chromosomes Here the most likely mechanism is non-disjunction two daughter chromosomes going to one cell and none to the other at anaphase It is proposed that in the pseudodiploid BHK and lymphoma cells non-disjunction probably occurred simultaneously in different

Table 2 SUMMARY OF KARYOTYPE ANALYSES OF CULTURED HUMAN LYMPHOMA CELL POPULATIONS

* Calculated for structurally normal chromosomes only

chromosome groups, that is, the loss of a chromosome in one group being compensated by a gain in another group, while retaining the normal diploid number of chromosomes per cell Furthermore, a widespread occurrence of anomalous distribution of chromosomes during cell division in both euploid and aneuploid cells can be deduced from the very high percentage of cells with entirely different karyotypes, in the various cell populations (from 78 per cent of EB3 ii to 100 per cent of EB1 iii *b*, EB2 ii and BHK samples)

It is then rather puzzling to find that, in spite of all this variation in karyotypes, modal and other chromosome numbers were nevertheless maintained In some cultures the frequency of replicates was so low that all that modal cells (such as pseudodiploid) had in common was the same chromosome number, the latter having selective advantage by some unknown mechanism Karyotype instability may be an inherent feature of these cell populations, for example, by genetic variability in the efficiency of the centromeres of different chromosomes

The finding of extensive karyotype instability within an apparently stable modal chromosome number requires assessment in relation to the stemline concept

Pseudo-stemline Concept

Cytogenetical studies on rat ascites tumours led Makino[25] to conclude that the genetic behaviour of tumour cell populations is determined by the modal cells (because they are in the majority and single-cell clones of modal cells could reproduce tumour characteristics) Such modal cells were termed stem-cells and could be recognized by having the same karyotype The evolution of new stemlines during tumour progression then explained changes in the character of transplanted tumour cell populations

Present studies conflict with the stemline concept as defined because no true stemlines were found in either the hamster or human lymphoma cell populations during a period of consecutive observations adequate for selection of new stemlines. There was such a wide variation in karyotypes that modal cells could only be distinguished in terms of chromosome number alone Nevertheless, because these cells formed the majority of consecutive subcultured populations they were chiefly responsible therefore for growth, like stem cells If so, the stemline concept should be defined in terms of what the cells do, rather than what they look like We can then extend the concept to another category of stem cells It is proposed that when modal cells can only be characterized by having the same chromosome number, but not by their karyotype, then they should be called a "pseudo-stemline" Such a situation has also been found in current studies on HeLa cultures The modal chromosome number has remained stable over several months, although the modal cells had very unstable karyotypes so that no two cells were found to have identical karyotypes

Indications of the possible significance of the extensive karyotypic variation (found within pseudo-stemlines and other chromosome numbers) were obtained by further analysis of karyotypes per population

Balanced Cytogenetical Polymorphism

In order to determine whether there is any chromosomal evidence for interaction between cells, the populations were analysed as a whole and compared Table 2*A* shows the distribution of chromosomes in the human karyotype groups A–G in Burkitt lymphoma cultures (including all chromosome numbers per culture), compared with the normal karyotype It can be seen that the proportions of chromosomes belonging to groups A–G in each population in the cultured neoplasms are highly significantly correlated with that of the corresponding normal male or female karyotype Reference to Fig 2 shows that the similar balance of chromosomal types within each population (exemplified in Table 2*A*) occurs despite wide variation in chromosome numbers per cell within and between cultures The most striking example is population EB2 ii, with chromosome numbers ranging from 46 to 166 and a mode of 86, that has a chromosome group distribution which does not depart significantly from that of a normal female karyotype

Table 2*B* (*a*) also shows that the close correlation with the normal balance of chromosome group distribution occurs in cell populations that significantly deviate from the number of structurally normal chromosomes/karyotype group/culture, expected in a normal cell population In addition, Table 2*B* (*b*) shows that these significant deviations from normal cannot be the result of the frequency of structurally abnormal chromosomes because they form too low a percentage of the observed deviations Non-disjunction is then considered to be the chief source of the observed balanced cytogenetical polymorphism, like the situation described by Barber in *Uvularia* pollen grains in 1941 (ref 26) except that here it is on a population scale It is suggested that this balance is maintained as follows (*A*) Selection by the *in vitro* culture environment of those karyotypic variants that will not upset the balanced distribution of chromosomes/group/population It is anticipated that such a balance of karyotype groups will only be recognizable in the early stages of heteroploid transformation and evolution of cell populations, when non-disjunction of structurally normal chromosomes is the chief source of polymorphism. Subsequent structural changes of chromosomes would obscure the possible presence of any balance in the distribution of physiologically active chromosomal material in the population as a whole. (*B*) Interaction by crossfeeding between physiologically inadequate mutant cells, in the same way as the well known examples of syntrophism in bacteria[27] could form a physiological basis for the observed chromosomal balance in mammalian cell populations. The well known feeder layer phenomenon, whereby certain mammalian cells can only grow in the presence of other cells[28], is supporting evidence. Furthermore, recent biochemical studies have indicated that metabolic co-operation can also occur between cultured mammalian cells (BHK)[29] by transfer of metabolic information.

The frequency of survival of physiologically inadequate chromosome mutations could then depend on the available supply of metabolic products from other cells.

Evolution

These observations indicate that co-operation as well as competition between cells affects the evolution of cell populations. This is a simple principle which has often been overlooked. Thus the balance of cell types obtained during the differentiation of chromosomal mosaics and chimaeras may be the product of intercellular interactions involving more co-operation than competition.

Because *in vitro* cell populations provide us with a model system for the study of evolution on a highly condensed time scale (where the average life cycle of the cell is 1 day rather than 20 yr for the whole organism, as in man) we may now venture to obtain further fundamental information about the stability of cytogenetical mechanisms in a shorter time.

I thank Miss S. Austin, Mrs S. Pearce and Mrs M. Occomore for assistance, the staff of the photographic department for much careful reproduction of photomicrographs to aid chromosome analysis, and Professor P. C. Koller for his stimulating interest and helpful comments about the manuscript. This investigation was supported by grants from the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), from the Medical Research Council, and by the National Cancer Institute, US Public Health Service.

Synthesis and degradation of protein occur in isolated "synaptosomes". Evidence for this is based on histochemical studies of cerebral cortical tissue which show the presence of lysosomes at the pre-synaptic ending of the neurone, and on biochemical studies.

EVIDENCE for protein synthesis at the synapse is conflicting. *In vivo* studies involving injected radioactively labelled amino-acids indicate that protein is synthesized almost exclusively in the perikaryon[1], and that significant radioactivity cannot be shown in protein from axonal or synaptic areas for a long time after the injection of labelled amino-acids[2]. Even amino-acid analogues which are not incorporated into protein do not produce measurable radioactivity in the axonal and synaptic areas after injection into the ganglion[3]. Furthermore, electron photomicrographs of neurones show identifiable images of ribosomes only in the perikaryon[4]. These results are consistent with the proposal of Weiss[5] that the proteins found in distal portions of the neurone arrive there by somato-axonal flow of moieties which were originally synthesized in the cell body.

In vitro experiments, on the other hand, indicate a potential for protein synthesis in both the axon and the pre-synaptic area. Sections of the axon of the Mauthner neurone of the goldfish fix labelled amino-acids into protein at a substantial rate *in vitro*[1]. It has also been reported that the "synaptosome" fraction derived from brain homogenates incorporates labelled amino-acids into protein when appropriately supplemented and incubated[6]. Brain mitochondria, including those present in the synaptic area, have been shown to synthesize protein at a rate which is at least as great as that of mitochondria isolated from other organs[7,8]. Finally, there are reports of the *in situ* formation of acetylcholinesterase in structures which bound the synapse[9].

It was suggested that these apparent contradictions would be resolved if protein was synthesized in distal portions of the neurone as follows[8]. Injected radioamino-acids are preferentially transported into the neurone at the cell body. Here, a very active machine for protein synthesis exists which, it seems, is not different from that found in other cells[10]. Protein is rapidly formed and slowly transported to distal portions of the neurone by the intraneuronal micro-circulation. Triggered by some unknown mechanism, the protein which is being transported is hydrolysed by lysosomes into its constituent amino-acids; these amino-acids are re-employed by local systems for the formation of characteristic protein. (A similar function has been suggested for multivesicular bodies in insects[11]. Here, however, there is evidence that lysosomes also transport the proteins to be degraded).

Thus in any experiment in which radioactivity is injected and sites of protein synthesis are identified by measuring radioactivity, it would seem that all significant synthesis occurs in the perikaryon because protein synthesis in more distal regions would be proceeding from amino-acids which were made up into protein at some time before the radioamino-acid was injected. Direct proof of this hypothesis is difficult to obtain, but the following consequences should be amenable to experimental verification: first, sub-cellular organelles which have the morphological appearance of lysosomes and which can be shown to contain acid hydrolases should be found in axonal and synaptic areas; second, it should be possible to obtain evidence for the hydrolysis of endogenous protein and the subsequent utilization of the derived amino-acids for *de novo* protein synthesis by structures found in synaptic areas.

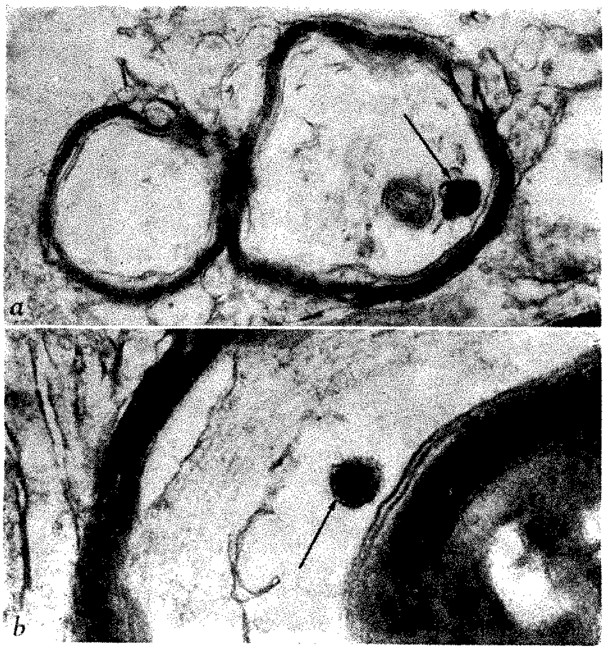

Fig. 1. *a* and *b*, Rat cortex incubated for the cytological demonstration of acid phosphatase. *a*, Transverse section of axon showing lysosome (arrow) containing reaction product. Organelle near lysosome is a mitochondrion. (× *c*. 16,575.) *b*, Longitudinal section of axon containing a lysosome. The latter is surrounded by a clearly visible membrane (arrow) and contains reaction product. (× *c*. 21,850.)

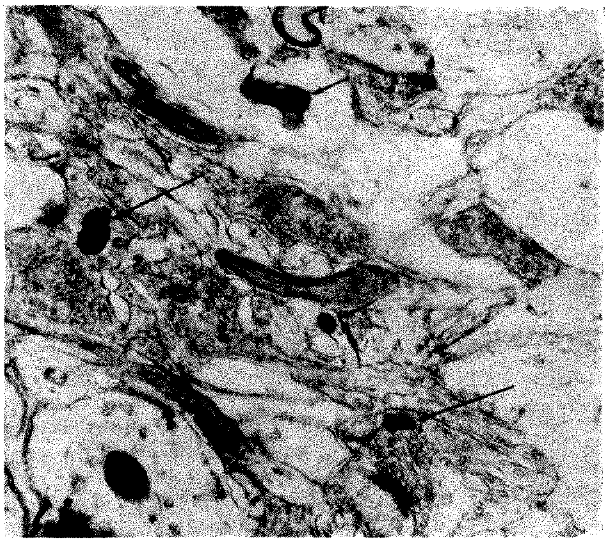

Fig. 2. Two of the numerous synapses in this section of cortex contain lysosomes on the pre-synaptic side (long arrows). Reaction product resulting from incubation of tissue for the cytological demonstration of acid phosphatase is present not only in these lysosomes but also in two others apparently located in dendrites (short arrows). (× *c*. 10,870.)

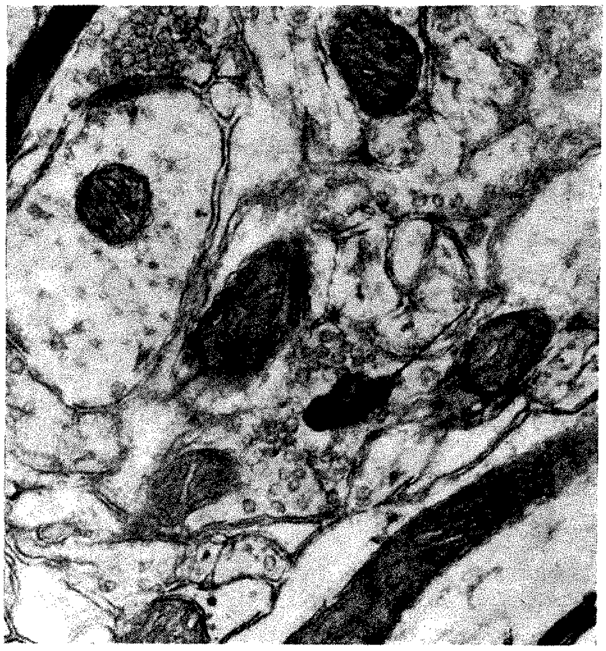

Fig. 3. Coarse and fine reaction product (arrow) resulting from histochemical incubation for acid phosphatase is clearly visible in a lysosome surrounded by pre-synaptic vesicles. (× *c*. 21,740.)

Histochemical Studies*

Cortical tissue for histochemical procedures was used from rat brains fixed by perfusion for 10 min with 3·5 per

[1] Incubations performed in the Dubnoff metabolic shaker at 37° C for 30 min. Total volume is 0·6 ml. and contains 0·167 M sucrose; 0·02 M *tris* at *p*H 7·6; 0·01 M *tris* phosphate at *p*H 7·6; 0·01 M magnesium acetate; 0·005 M α-ketoglutarate; 0·002 M ADP; 0·006 M mercaptoethanol; 0·03 μCi [^{14}C] L-leucine (specific activity averaged 250 mCi/mM); 0·04 M potassium chloride; and 0·1 M sodium chloride.

[2] Acid phosphatase activity = *OD* (410 mμ) as a result of *p*-nitrophenol being released after 30 min at 37° C (ref. 19).

[3] Radioactivity measured in Packard liquid scintillation counter.

[4] mg Protein determined by method of Lowry *et al.*[20].

[5] See Table 1 for isolation procedures.

[6] Malic dehydrogenase activity measured as the rate of NADH produced. Activity reported in fluorometer units/min/mg protein as measured in the Aminco-Bowman spectrophotofluorimeter[21].

[7] Bacteria counted on blood-agar pour plate after 3 days of incubation at 37° C. Counts averaged forty colonies/mg protein.

cent glutaraldehyde, and buffered to *p*H 7·2 with 0·05 M cacodylate. The tissues were washed in cacodylate buffer containing sucrose for several hours before immersion in the incubation medium. Very small blocks, no larger than 1 mm³, were incubated in the Gomori medium for acid phosphatase[12] at *p*H 5·5 for 1 and 2 h. Control tissue was incubated in complete medium containing 0·01 M sodium fluoride as inhibitor and in medium without substrate. The incubated tissue was subjected to osmosis, dehydrated and embedded in DER 'Maraglas'.

Deposits of lead phosphate were seen in membrane bound organelles in all portions of the neurone, the cell body, dendrite, axon and pre-synaptic endings (Figs. 1–3).

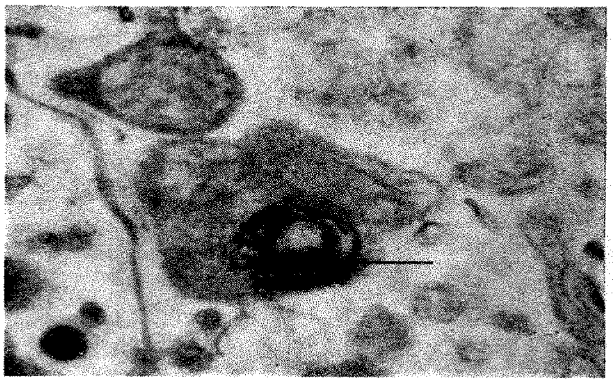

Fig. 4. A synaptosome from a pellet incubated for the demonstration of acid phosphatase showing reaction product (arrow) in an irregular vacuole containing membrane-like structures. (× *c*. 16,575.)

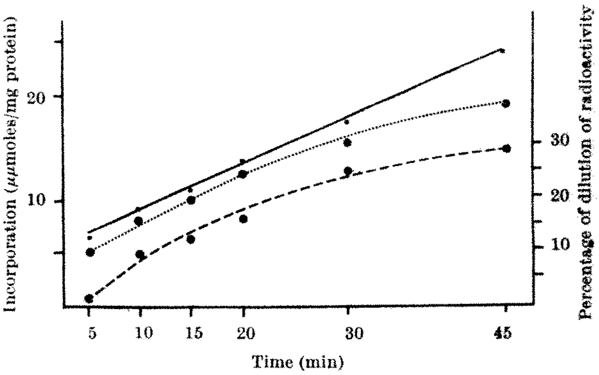

Fig. 5. Protein synthesis by brain mitochondria. Incubation medium and conditions were identical to those described in Table 2 (footnote 1) except that 1·4 mμmoles ^{14}C-tyrosine (specific activity 367 Ci/min) was added in place of ^{14}C-leucine. A pellet enriched with mitochondria was equivalent to 0·9 mg Lowry protein (average of four experiments). Endogenous tyrosine averaged 0·4 mμmoles/mg protein determined on TCA supernatant by method of Udenfriend[16]. This analysis for total free tyrosine was repeated at each of the time intervals designated in the figure. Incorporation of ^{14}C-tyrosine: ———, corrected for isotope dilution; . . . . , assuming constant specific activity. – – – –, Percentage of dilution of radioactivity.

These had the typical morphological appearance of lysosomes. In some organelles, in the pre-synaptic ending, deposits of reaction product were localized on the surface of membranes of what seemed to be multivesicular bodies. In the present study, lysosomes in the pre-synaptic ending and in the axon differed from those in the perikaryon in that they were uniformly smaller, had irregular contours and did not usually have the same complex structure seen in the larger perikaryal lysosomes (Figs. 1–3). It is assumed that pre-synaptic lysosomes are formed in the cell body[13] and that they undergo alteration as they migrate to the distal portions of the cell. On the other hand, the question has been raised[14] as to whether all lysosomes are modifications of the same organelle, or whether they differ in the kinds of enzymes which they contain. It is possible that the lysosomes which migrate are a different species and not variations of the lysosomes which reside in the cell body.

Histochemical evidence for acid phosphatase activity in preparations of synaptosomes which were used in the biochemical studies reported here was also obtained (Fig. 4).

Biochemical Studies*

Pellets were obtained by centrifugation of brain homogenates as described in Table 1. Acid phosphatase was found at all stages of mitochondrial enrichment (Table 2),

---

* Experiments conducted in the Department of Biochemistry at the Institute of Living by G. G. Deanin and M. W. Gordon.

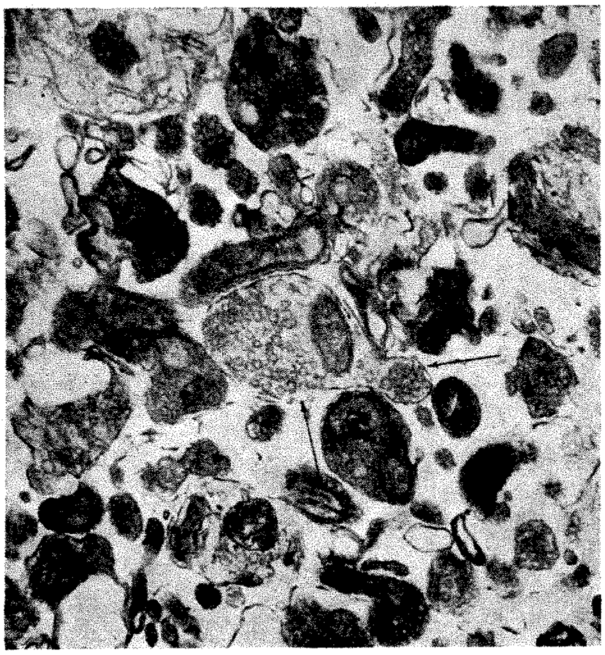

Fig. 6. Fraction from cortex of rat brain consisting almost exclusively of synaptosomes (arrows). The synaptic vesicles as well as mitochondria are well preserved. (× c. 7,720.)

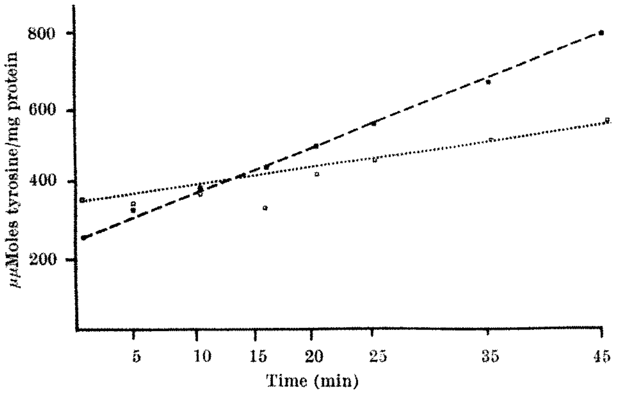

Fig. 7. Protein hydrolysis by synaptosomes. The analysis for total free tyrosine was performed on a TCA supernatant aliquot of a synaptosomal preparation for each of the indicated time periods and temperatures (. . . , 20° C; - - - - 37° C) by the fluorometric method of Udenfriend[16].

even in those preparations containing the highest malate dehydrogenase specific activity. These pellets can incorporate ^{14}C-leucine into protein (Table 2). Confirmation that protein synthesis, not N-terminal labelling, accounts for the acid-precipitable radioactivity was obtained by treating incubated pellets with Sanger reagent[15], hydrolysing with hydrochloric acid, extracting the hydrolysate with ether and counting the organic extract in a scintillation counter. Less than 1 per cent of the acid-precipitable activity was ether soluble. Furthermore, bacterial contamination was so low as to be negligible (Table 2).

In other experiments using preparations enriched with mitochondria (fraction *A*-6), the rate of incorporation of ^{14}C-tyrosine, an amino-acid for which a very sensitive method of detection exists[16], was followed as a function of time (Fig. 5). In addition, at each of the time intervals measured for incorporation of radioactivity, the total concentration of tyrosine in the medium was estimated. This estimate of the total tyrosine permitted a calculation of its continuously changing specific activity. Assuming instantaneous equilibration of the medium tyrosine with that incorporated into the acid-precipitable Sanger reagent negative fraction, a re-calculation of the net incorporation of tyrosine was made. With this assumption, the fixation of tyrosine into protein is a linear function of time for 45 min (Fig. 5). Bacteria-free mitochondria isolated from liver also synthesize protein at a linear rate for approximately this length of time[17].

Direct evidence for proteolytic activity was also obtained from synaptosomal preparations (fraction *B*-5, Fig. 6). Incubations of synaptosomes were carried out at both 20° and 37° C in a 'Dubnoff' metabolic shaker. Samples were removed at intervals and the amount of tyrosine formed was estimated by a fluorometric method[16]. Fig. 7 shows the increase of tyrosine with time at both temperatures.

The evaluation of the kinetics of protein synthesis by "synaptosomes" seems to require the consideration of additional variables. Like nuclei[18], "synaptosomes" rapidly concentrate amino-acids from the medium but fail to retain them. Furthermore, the rate of loss seems to be a more sensitive function of temperature than is the rate of accumulation of the amino-acid. At 20° C in the presence of 2 μM tyrosine the synaptosomal concentration

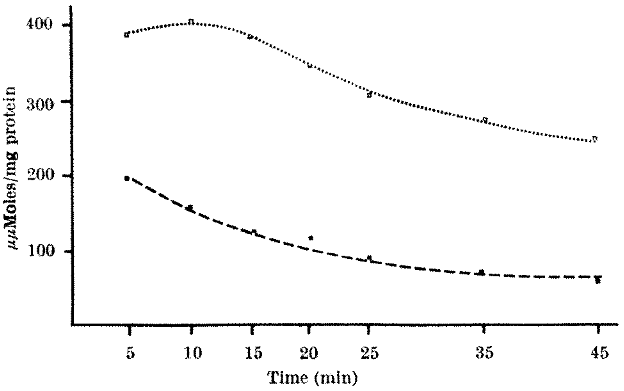

Fig. 8. Transport of ^{14}C-tyrosine into synaptosomes. Incubation medium and conditions as in Table 2 (footnote 1) except that 2·2 mμmoles of ^{14}C-tyrosine (specific activity 367 Ci/min) replaced the ^{14}C-leucine. After incubation for the indicated times and temperatures (. . . . , 20° C; - - - - , 37° C) an aliquot was removed into an ice-cold solution of 0·32 M sucrose, centrifuged for 10 min at 12,000*g* and washed twice with the same concentration of sucrose. The pellet was suspended in ice-cold 0·3 M TCA, centrifuged and an aliquot of the supernatant was counted in Bray's solution in a scintillation counter. Protein was determined by the method of Lowry[20].

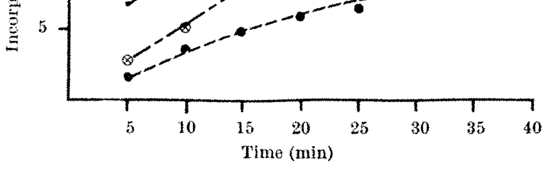

Fig. 9. Protein synthesis by synaptosomes. Conditions and methods identical to those of Fig. 1 except that the experiment was run at 20° C using concentrations of ^{14}C-tyrosine as indicated below. Isotope dilution values were estimated by direct measurement of tyrosine[16] at each time interval.

■——■, 8·5 μM tyrosine } Uncorrected incorporation
● - - - ●, 2·3 μM tyrosine }
□ . . . □, 8·5 μM tyrosine } Corrected for isotope dilution
⊗— — —⊗, 2·3 μM tyrosine }

of amino-acid is greater than at 37° C for all equivalent time periods examined (Fig. 8). Studies of protein synthesis were therefore carried out at 20° C where the possible effects of a rapidly changing internal concentration of tyrosine would be less marked. Nevertheless, correction for isotope dilution linearized the data at low concentrations of medium tyrosine for much shorter time periods than with mitochondrial pellets (Fig. 9). If the application of the isotope dilution corrections is a legitimate procedure, however, the same experiment run at a higher medium concentration of tyrosine should result in a longer period of linearity in uptake because the effect of isotope dilution should be minimized. This proved to be the case (Fig. 9).

Explanations for the reduction in the rate of uptake after only 20 min of incubation compared with 45 min for mitochondria have not been thoroughly worked out. It is possible, however, that the internal concentration of free tyrosine in the "synaptosome" is the variable which accounts for this more rapid fall-off in uptake.

The natural substrates for lysosomal activity at the synapse are not known. As mentioned earlier, there are two possible routes by which protein can reach the distal portions of the neurone: protein can be incorporated in multivesicular bodies or lysosomes and transported by these organelles[11]; or alternatively, because there is a net flow of cytoplasm from the cell body to the distal end of the axon[5], it is interesting to consider that lysosomes may digest portions of the cytoplasm in the pre-synaptic ending. If this were so, such lytic activity could in turn be a factor in promoting somato-axonal flow. Whatever the source of protein for proteolysis, the presence of synaptic lysosomes, which have been demonstrated both histochemically and biochemically, may create the amino-acid resource for protein synthesis at the pre-synaptic ending.

This investigation was supported in part by grants from the US National Institutes of Health and the US Public Health Service. We thank Mrs Bina Bergner for expert technical assistance.

Adjuvanticity of Vitamin A

by
D. W. DRESSER

National Institute for Medical Research,
Mill Hill, London

Vitamin A may act as an adjuvant through its effect in damaging lysosomal membranes, in this way stimulating cell division. Possibly this stimulation of cell division at the time when antigen is available in the cell leads to the induction of immunity and not paralysis.

BOVINE gamma G protein is a non-immunogenic antigen in mice, in contrast to bovine gamma A protein. A particle-free solution of the gamma G protein will induce a specific state of immunological paralysis if injected into mice in amounts greater than 10 µg. Combination of the non-immunogenic antigen with Freund's adjuvant, *Bordetella pertussis*, or adsorption of the protein onto a particulate substance such as aluminium phosphate, makes the protein immunogenic so that, on injection into mice in one of these forms, a powerful immune response is started[1,2]. The gamma A protein is defined as immunogenic because it will immunize as a particle-free solution without an extrinsic adjuvant being necessary; the gamma A is considered to possess its own "adjuvanticity"[3]. The property of adjuvanticity possessed by, or added to, an antigen could therefore be considered as a switch controlling one of two possible cellular responses to antigen which are shown.

This paralytic effect of bovine gamma G protein antigen in the absence of adjuvanticity can be used to assay various substances for adjuvant properties in mice[3]. The degree of adjuvanticity can be measured by estimating the degree of immunity induced to the injected particle-free gamma G, or alternatively it can be measured by the decrease in the degree of paralysis induced by the same protein. The definition of adjuvanticity used here is restricted by comparison with the accepted definition of an adjuvant as a substance which increases the degree of an immune response to an immunogenic antigen[4]. Most adjuvants are complex substances, such as Freund's adjuvant[4] or endotoxins such as that of *B. pertussis*[5]; these substances also possess adjuvanticity in the sense used here. The complexity of these substances lies both in their chemistry and in the fact that they are antigens in their own right: it is for this reason that an effort was made to find some simple non-antigenic adjuvants. Certain non-ionic detergents and fatty acids were found which acted in this way[3]. Other studies have shown the adjuvant properties of aliphatic nitrogenous bases in guinea-pigs and mice[6]. Both studies agree with the view that damage to cellular membranes could be one of the first effects of some adjuvants. Vitamin A is known to have detectable effects on biological membranes[7]. This communication reports experiments which show that vitamin A has adjuvant properties.

Effects of *B. pertussis* and Vitamin A on Mice

CBA male mice, 4–5 months old, were used in these experiments. *B. pertussis* (Glaxo) were injected in saline in the numbers indicated in Fig. 1, and vitamin A alcohol

('Retinol', Koch-Light), dissolved in 0·5 ml. of liquid paraffin (BP), was injected in the amounts indicated in Fig. 2. The vitamin A and the *B. pertussis* were injected subcutaneously in the dorsal region 1 day before the intraperitoneal injection of 0·5 mg or 5·0 mg of a particle-free (RCF = 30,000*g*, 25 min) bovine gamma globulin (BGG—Armour and Co.). Commercial bovine gamma globulin contains 80–90 per cent gamma G protein and 8–16 per cent gamma A protein (unpublished data). The degree of immunity induced by the injected gamma G protein was measured one month later by the antigen-elimination test[2]. There were six or seven mice in each group for which the geometric mean ($\log_2$) response was estimated by the published method[2].

Fig. 1 shows the effect of injecting different amounts of *B. pertussis* into mice subsequently injected with either 0·5 mg or 5·0 mg of particle-free bovine gamma globulin. The degree of immunity obtained is dependent both on the amount of adjuvant and at least to a certain extent on the amount of antigen. Fig. 2 shows that a similar effect is obtained when increasing amounts of vitamin A are injected into mice injected with 0·5 mg of particle-free bovine gamma globulin. Table 1 shows that mice which failed to show immunity in the adjuvant assay were immunologically paralysed.

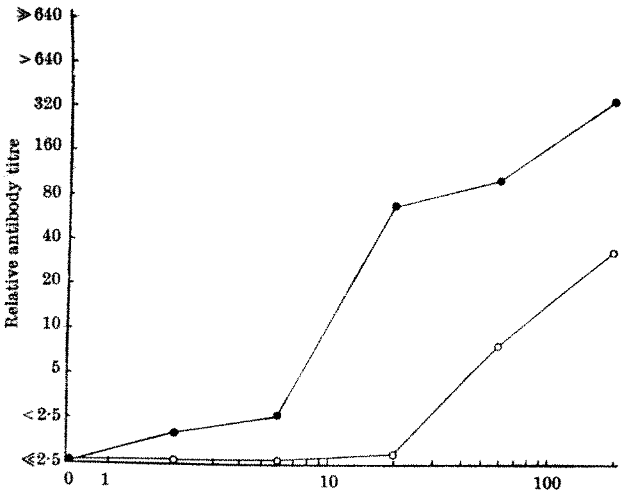

Fig. 1. Dose response effect of *B. pertussis* injected subcutaneously 1 day before the intraperitoneal injection of 5 mg (●) or 0·5 mg (○) of particle-free bovine gamma globulin. The abscissa is the number of pertussis organisms. The ordinate is the antigen elimination response 1 month after the initial treatment.

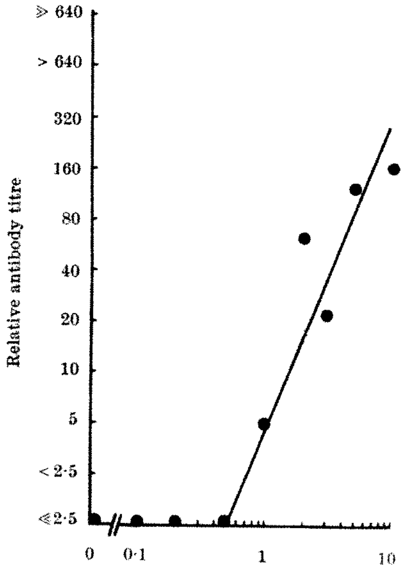

Fig. 2. Dose response effect of vitamin A alcohol in 0·5 ml. liquid paraffin, injected subcutaneously 1 day before the intraperitoneal injection of 0·5 mg of particle-free bovine gamma globulin.

Possible Reasons for These Effects

A dose response effect of both a complex adjuvant (*B. pertussis*) and a simple adjuvant (vitamin A) has been shown. The antigen dose effect seen in Fig. 1 is at a level about 10 to 100 times higher than when alum precipitated bovine gamma globulin is used (unpublished data). This could be caused by the relative efficiencies of antigen uptake and it may indicate a role of macrophages in the response to a particulate antigen. Recent experiments[8] (and unpublished data) show that increased phagocytosis is unlikely to be the only factor accounting for the action of adjuvants. It is clear, however, that the stimulation of macrophages to "pre-process" antigen[9], or to release such material more freely, has not been ruled out as one possible mechanism of adjuvant action.

At the cellular level, immunological paralysis as defined by the response of the whole animal may result because all the lymphoid cells are paralysed, whereas an immune response by the animal could be caused by relatively few cells producing antibody at the same time that the majority is paralysed. It would be misleading therefore to extrapolate from results of experiments on whole animals to possible cellular mechanisms, and in the context of this communication it is clear that any conclusion concerning the action of adjuvants (adjuvanticity) may only apply to a restricted population of cells.

The portion of an immunogenic antigen which is responsible for adjuvanticity may in certain cases be identical with antigenic determinants and in most cases is at least closely associated with antigenic determinants on the same molecule or cell. The response to this property of adjuvanticity may be the result of one particular cellular response to stimuli from a wide range of different kinds of substance. For instance, substances with known adjuvanticity include toxins, cellular antigens, carbohydrates, non-ionic detergents, aliphatic nitrogenous bases and vitamin A. Gall[6], on the basis of his experiments with aliphatic nitrogenous bases, has suggested that the action of adjuvant in increasing the degree of an immune response is indirectly caused by damage to lymphoid cell membranes. It is now further suggested that one result of this damage, either directly or in some cases through damage to macrophages, is a stimulation of cell division by immunologically competent cells. Recent work[10] shows that the increased number of peripheral lymphocytes induced in mice after the injection of *B. pertussis* does not arise by cell division. This finding restricts the population of cells where adjuvant stimulated division could occur.

The osmotic sensitivity of lysosomes has been shown to be increased by a non-ionic detergent ('Triton *WR* 1339')[11] and it has also been shown that vitamin A increases the permeability of lysosomal membranes[12]. Earlier experiments[13] showed that vitamin A increased the rate of cell division of chick fibroblasts *in vitro*. On the basis of these and their own observations, Allison and Mallucci[14] suggested that lysosomes are concerned with the start of cell division, and Weissman[15] has speculated on the possible connexion between lysosomal stability and various autoimmune diseases. It seems possible that some adjuvants such as vitamin A or non-ionic detergents could act through their effect in damaging lysosomal membranes, and in this way stimulate cell division. It is possible that this stimulation of at least one cycle of cell division at the time that antigen is available in the cell leads to the induction of immunity rather than paralysis. Post-inductive proliferation of pre-antibody-producing cells is irrelevant here. Such a definition of adjuvanticity would be compatible with the "recognition mechanism" which it was suggested acted as a paralysis/immunity "switch" in a proposed cellular mechanism of immunological paralysis[2,16].

I thank Drs J. H. Humphrey and G. L. Asherson for their helpful discussion, and Miss J. Dilley for technical assistance.

Kinetics of Myofilament Activation in Potentiated Contraction: Staircase Phenomenon in Human Skeletal Muscle

by
JOHN E. DESMEDT
KARL HAINAUT
Laboratory of Pathology of the Nervous System and Brain Research Unit, University of Brussels

Staircase potentiation in skeletal muscle depends on an intensification of the twitch "active state" early in the contraction cycle. A working hypothesis of this is proposed.

THE isometric twitch elicited by a single electrical stimulus delivered either to the motor nerve or directly to the muscle is usually discussed in terms of Hill's model[1] of a two-component system—for example, contractile elements arranged in series with passive elastic elements. The latter seem to be partly located in the tendon and partly distributed along the muscle fibres[2]. The "active state" which is the capacity of the muscle to shorten or develop tension obviously has a very limited duration after a single stimulus. Even if the contractile elements could develop full tension instantly, the twitch force recorded at the tendon would rise rather slowly as the series elastic elements were being stretched; furthermore, there would not be enough time for the twitch tension to approximate tetanic tension. In his model, Hill postulates that the "active state" rises rapidly to its maximum, even in a single twitch. Twitch potentiation by drugs is then ascribed to prolongation (rather than intensification) of the "active state" whereby twitch force is enabled to approximate tetanic force more closely because more time is available for stretching the series elastic elements[3-5]. Such a view is challenged by the present findings that in staircase potentiation the activation of myofilaments seems to be intensified but not at all prolonged.

"Active State" Intensity in a Single Twitch

That the series compliance interacts with an "active state" of rapid onset and subsequent slower decay to determine the form of the isometric twitch is well substantiated, for example, by the fact that added[6] or reduced[1] series compliance will decrease or increase twitch tension more than tetanic tension. The subsidiary proposal, however, that the "active state" would be established to full intensity even after a single stimulus seems both unnecessary and inadequately substantiated. One argument for this latter view is that when a frog or toad muscle at 0° C is quickly stretched after a single stimulus, thereby reducing the series compliance, the contractile elements can bear, for a short time, a tension which is larger than the normal twitch tension[1]. It should be appreciated, however, that the increased tension does not always precisely match, and indeed sometimes exceeds, the tetanic tension. Furthermore, a muscle forcibly stretched during tetanus will sustain for a short while a greater tension than the maximum tension actively developed by the same muscle when it is extended to the same length before the tetanus[7-9]. Indeed, the intensity of the active tension-generating process in the sliding filament system cannot be equated with the capacity of the system to resist applied stretch[10,11].

Contrary to several statements in the literature, other methods in use provide no direct evidence that a single stimulus would elicit a plateau of maximum "active state". When an isometrically contracting muscle is released a fixed distance (0·5–3 mm) at various times after a stimulus, the tension recorded falls abruptly and is then redeveloped in proportion to the level of the (decaying) "active state" still present at that time[12]. In frog muscle at 0° C there still occurs some redevelopment of tension as late as 0·9 sec after a single stimulus[11]. The "active state" decay is further prolonged during nitrate potentiation[4]. While the quick-release analysis discloses the time course of the decay of "active state" from its early peak, however, it provides no evidence on the absolute level of activation which is achieved during this early peak. Also the experiments cannot be easily performed on the much faster mammalian muscle twitch.

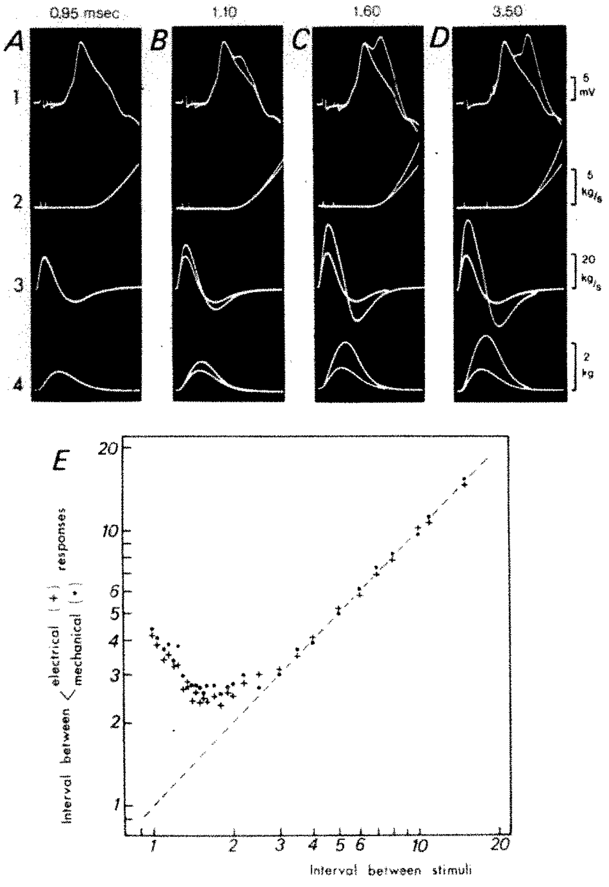

Fig. 1. Normal adult man. Intramuscular temperature 37° C. *A–D*, Cathode-ray oscillograms of responses of the adductor pollicis muscle *in situ* to supramaximal electric pulses delivered to the ulnar nerve at the wrist. In each frame the response to a single shock is superimposed on the response to two shocks at the interval indicated on the top. The two upper traces present on a fast sweep the belly-tendon electrical response (1) and the first differential of the isometric myogram (2). The two lower traces present on a slower sweep the same first differential (3) and the isometric myogram (4). *E*, Relation between the interval of the two shocks delivered to the motor nerve (abscissa) and the separation interval of the muscle responses elicited by each of the two shocks (ordinate). Notice the similarity of the latter for the electrical and the mechanical responses.

According to another method the minimum frequency of repetitive stimulation necessary to achieve tetanic fusion[12,13] or maximum rate of tension development[14] is evaluated and the critical intervals necessary to either maintain or establish full activation of the myofilaments are thought to correspond to the duration of the postulated "active state" plateau. Using mechanical transducers of high resolution one must stimulate at rates as high as 600/sec (ref. 15) or 425/sec (ref. 16) in experiments on fast mammalian muscles. The same feature can be tested more simply with only two stimuli[14], for the contraction elicited by two stimuli should only separate from that elicited by a single stimulus when the latter becomes able to add an increment of "active state". Differentiation of the tension record increases the resolution of the method and shows that the two curves separate after 44 msec in frog muscle at 0° C (ref. 14). In mammalian fast muscles at body temperature the separation occurs as early as 4 msec (ref. 9, 17) or even 2–3 msec (refs. 15, 16). The question is whether the minimum interval is determined by the duration of the "active state" plateau or by some other factor.

Data such as those shown in Fig. 1 indicate that it is, in fact, the duration of the refractory period for electrical excitation which sets the lower limit to the interval for eliciting an increment of mechanical activation in double shock experiments[15]. The tests are performed on normal adult men. Four cathode-ray oscilloscope traces are simultaneously recorded onto 35 mm film: from below upwards, the isometric myogram of the adductor pollicis muscle (trace 4) and the rate of tension change obtained by electronic differentiation of the myogram (trace 3) on a slow time-base sweep; the same differential function with amplification increased ten times horizontally and four times vertically (trace 2) and the belly-tendon electrogram of the adductor pollicis muscle on a similar time-base (trace 1)[18]. Supramaximal electric pulses are delivered through needles to the ulnar nerve at the wrist, at the intervals indicated in msec on the top of records *A–D* and in the abscissa of graph *E*. In each record the response to double-pulse stimulation is photographically superimposed on the response elicited by the first pulse alone. The intramuscular temperature checked with a thermistor needle is 37° C. The electronic differentiation is linear up to four times the maximum rates of tension changes recorded, even when tested with ramp functions of only 2 msec duration.

In the experiment illustrated, the reponses elicited by two pulses at 0·95 msec or less (*A*) are identical to that for a single pulse. At intervals of 1·00 or 1·10 (*B*) msec a small hump appears on the electrogram about 4 msec after the beginning of the response to the first pulse. The rate of tension change for single shock indicates a mechanical latency (including nerve conduction and neuromuscular transmission) of 7·5 msec; the trace for two pulses at 1·10 msec separates about 4 msec later (*B*, 2). As the interval increases to 1·60 msec the separation interval decreases to about 2·50 msec, both for the electrical and mechanical responses (*C*). This curious effect suggests that the second volley now propagates faster in the motor nerve as the relative refractor state left by the first response dissipates, and that it also acquires a greater transmission potentiality at the motor endplate. For greater separation of the two stimuli the interval between the muscle response to the first and second volleys increases and actually equals the corresponding interval between the two shocks. This appears in graph *E* in which the interrupted line is drawn through the origin with a slope of one. The muscle is thus irresponsive for about 2·5 msec, but two stimuli delivered to the motor nerve at shorter intervals, down to about 1·0 msec in this instance, can still elicit a second muscle response because the nerve functions as a time buffer through slowing of conduction of the second volley. In the present argument the principal point stressed is that the earliest separation intervals are equal throughout the test for the electrical and for the mechanical responses of the muscle.

The significance of this double-shock test turns out to be quite different from the one proposed by those who failed to record simultaneously the electrical response of the muscle[14,16,19–21], for they overlooked the fact that the refractory state of the muscle electrogenic membrane is the true limiting factor at short intervals. In other words, the second stimulus delivered before the critical interval fails to increase the rate of tension development beyond that in a single twitch, not because the "active state" generated by the preceding stimulus would then be maximum (and therefore impossible to increase any further, as argued by MacPherson and Wilkie[14]), but simply because the second stimulus is ignored by the still irresponsive muscle membrane. Such evidence implies that a single stimulus cannot possibly elicit a maximum plateau of "active state" because: (1) activation of myofilaments is not abrupt but takes a finite time to develop[2,10], and (2) as soon as 2·50 msec after the muscle has started developing tension (the minimum separation interval in Fig. 1, *E*) the intensity of activation can be further augmented. This conclusion is in line with present views[22,23] that myofilaments are activated by calcium release from sarcoplasmic reticulum (SR) during depolarization of the muscle membrane beyond a level called the "mechanical threshold"[24] and that subsequent sequestration of the myoplasmic calcium in a sarcoplasmic

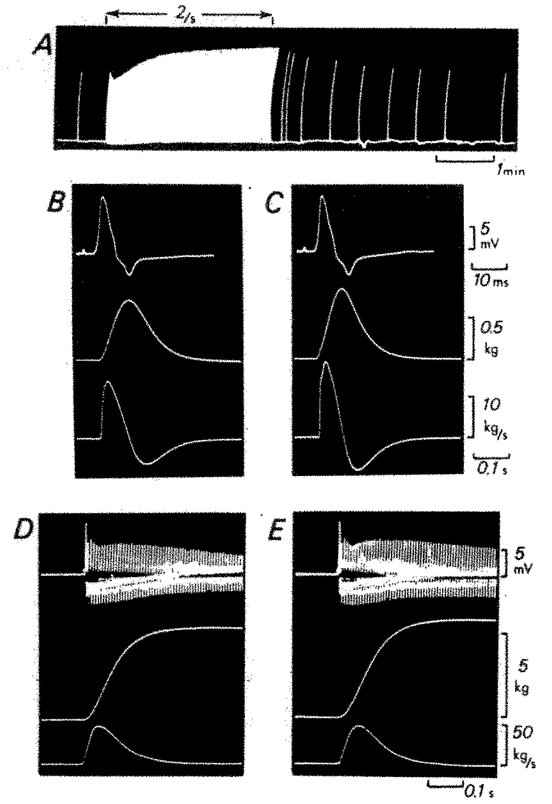

Fig. 2. *A*, Normal adult man. Continuous slow-speed polygraph record of the isometric myogram of the adductor pollicis muscle stimulated infrequently through its motor nerve, except for a series at 2/sec. *B–E*, Normal adult woman. Cathode-ray oscillograms of responses to the first (*B*) and the 200th (*C*) supramaximal shocks in a continuous series at 2/sec. From above downwards, the belly-tendon electrical response (on a faster sweep), the isometric myogram and its first differential. *D*, Tetanic response to supramaximal shocks at 125/sec, elicited at the peak of the staircase potentiation of the twitch. *E*, Tetanic response elicited in the same muscle after dissipation of the staircase phenomenon. Notice that the maximum rate of tension development (third trace) is similar in *D* and *E*.

calcium sink causes relaxation[23,25,26] and determines its actual speed[27]. With two or more stimuli at close intervals each muscle action potential triggers the intracellular release of an additional amount of calcium at a time when the SR sink has not yet removed all the free calcium liberated by the preceding spike. Because the contractile activation depends on the concentration of myoplasmic calcium over about a ten-fold range from 0·2 μM (refs. 23, 26 and 28) the "active state" must be subject to gradation in its intensity as well as in its duration.

Twitch Potentiation

In chemical potentiation such as produced by caffeine, nitrate, zinc and so on, the twitch tension is increased but the tetanic tension is not, while the contraction time and the relaxation time of the twitch are both increased[3,30]. The latter changes are accounted for by a slowing of the decay of "active state", as is indeed evidenced by quick-release experiments[3–5]. This slowing allows the twitch tension to approximate the tetanic tension more closely because the contractile elements have more time for stretching the series elastic elements. The potentiation is indeed smaller when the twitch tension P_t is closer to the maximum tetanic force P_0 (ref. 31). At 0° C the decay of "active state" is also slowed down by the chemical potentiators, but little actual increase of P_t occurs because the ratio of P_t to P_0 is close to unity[4,5]. Recent studies using a more sensitive recording technique disclosed yet another feature of the potentiated twitch, namely, an increase in the rate of tension development[32–34]. This suggests that the potentiators not only prolong the decay of the "active state", but also increase the intensity of myofilament activation earlier in the contraction cycle. The two effects occur together in chemical potentiations, but they can be dissociated from each other. The following evidence indicates that staircase potentiation is unique in its dependence on the intensification factor only.

Staircase Potentiation in Human Skeletal Muscle

When a rested muscle is stimulated at a rate of 0·5–3/sec, the twitch force gradually increases to reach a new steady state level. This is the classical staircase phenomenon first described in the frog heart[35] and also studied in the skeletal muscles of lower mammals[36,37] and of man[38]. In Fig. 2*A*, the isometric myogram of the adductor pollicis muscle of a normal adult man is recorded on a slow-moving polygraph. Supramaximal electric pulses are delivered to the ulnar nerve at infrequent intervals, except for an uninterrupted series at 2/sec for 3 min. During the series, the force P_t decreases progressively in the first ten–twenty twitches (negative staircase) and thereafter increases steadily (positive staircase) to reach a plateau equal to 136 per cent of the initial P_t. When the 2/sec stimulation is interrupted, P_t returns to control value in a few minutes. In the twenty-one normal adult muscles included in this study the mean initial negative staircase is $-8·7$ per cent and the mean maximum staircase potentiation is $+24·5$ per cent. Characteristic features are illustrated by the cathode-ray oscillograms of the first and two hundredth responses in a 2/sec series (Fig. 2*B* and *C*). The latency of the muscle electrical response does not change. The first negative phase of the potential shows no significant change in its voltage, but its mean duration is decreased to -7 per cent. The mean voltage of the second positive phase is increased by $+18$ per cent. The latter two effects are recorded rather early in the series and are not parallel to the twitch potentiation: they are probably related to an acceleration of the conduction of the muscle spike[18]. Changes in neuromuscular transmission or repetitive discharges are excluded. The two hundredth twitch of the series is not only stronger than the first but its time course is accelerated. The mean contraction time *CT* decreases by -14 per cent and the mean relaxation

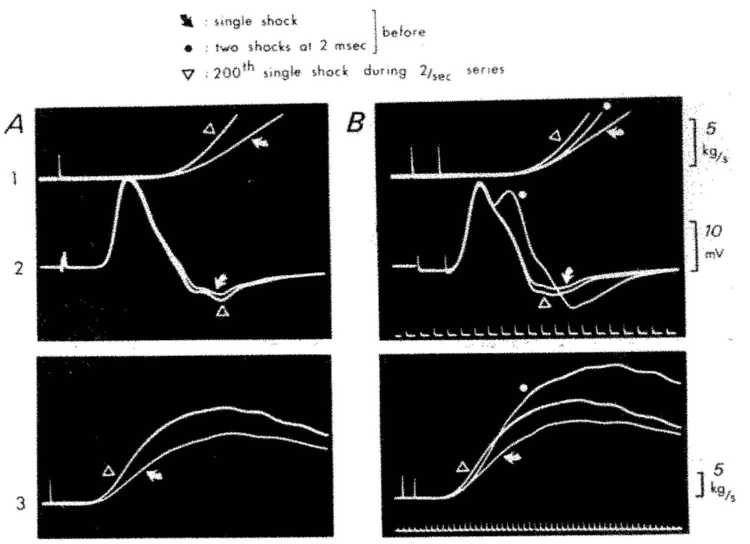

Fig. 3. Normal adult man. Cathode-ray oscillograms of responses to single or double supramaximal shocks delivered to the ulnar nerve at the wrist. From above downwards, the first differential of the isometric myogram (1) and the belly-tendon electrical response (2) on a fast sweep, and the first differential of the myogram (3) on a slower sweep. Horizontal calibrations in milliseconds. Photographic superimpositions of traces as indicated by the symbols (see text).

time $T\frac{1}{2}R$ decreases by -13 per cent. The mean maximum rate of tension development which we call R_t, given by the upward peak of the first differential of the myogram, is increased by $+37$ per cent. The mean maximum rate of relaxation S_t, given by the downward peak of the first differential, is also increased by $+34$ per cent. The consistent shortening of the time course of the potentiated twitch rules out the current explanation[39] which postulates a prolongation of the decay of "active state" in staircase. On the other hand, it is interesting that the maximum capability to generate force is not much affected by the staircase phenomenon. The maximum tetanic force P_0 recorded just after 3 min of uninterrupted 2/sec series (Fig. 2*D*) is equal to, or slightly less than, the P_0 recorded in the same muscle after the staircase effect has dissipated (Fig. 2*E*). The maximum rate of tension development in tetanus R_0, given by the upward peak of the first differential, is equal in both records (Fig. 2*D* and *E*, third trace). Thus the maximum intrinsic velocity of the muscle is not increased by staircase. Because the potentiated twitch is shortened rather than prolonged, the phenomenon can only be explained by an increase of the "active state". The evidence of Fig. 3 is relevant on this point. The first and two hundredth responses are superimposed on the same photographs using fast oscilloscope sweeps. The electrical response shows the slight changes described earlier (*A*2). The first derivative of the myogram presents not only a larger peak (*A*3) but also a very early increase (*A*1) so that the mechanical latent period appears shorter for the two hundredth twitch. Fig. 3*B* presents a similar display but with the further superposition of the responses to two shocks at 2 msec delivered before the 2/sec series. For such closely spaced double stimulation the rate of tension development separates from the curve for a single shock after 2·5 msec at the earliest (compare Fig. 1), and there is no evidence for any shortening of the mechanical latent period. Later in the contraction cycle the curve for double shocks (dot) crosses the curve for the potentiated single twitch (triangle) and it reaches a larger peak (Fig. 3, *B*3). These recordings on a fast sweep thus emphasize a unique feature of the potentiated contraction, namely, a mechanochemical change which occurs very early in the contraction cycle and which is not elicited by closely spaced double shocks. Our working hypothesis is that the prolonged stimulation at low rate induces two changes: (1) a lowering of Hodgkin and Horowicz's mechanical threshold[24,40,41] whereby a roughly unchanged muscle action potential elicits an earlier and larger calcium release from sarcoplasmic reticulum and the twitch "active state" is intensified; and (2) an acceleration of the subsequent process of uptake of myoplasmic calcium by the reticular calcium sink which shortens the relaxation of the potentiated twitch.

While this evidence is at variance with current interpretations of twitch potentiation, it also emphasizes that, in this respect, skeletal muscle is not as different from heart muscle as is usually believed. In heart muscle the increase of frequency of contraction (positive inotropy) augments the contraction force and rate of tension development and decreases the contraction time[42-44]. A shortening of latency of contraction is also described[44]. Clearly the staircase potentiation in heart muscle is related, not to prolongation of "active state", but either to intensification of the "active state" or to a shift of the force–velocity relation[43,46]. Sonnenblick[44,45] favours the latter hypothesis for heart muscle in which he recognizes a peculiar "ability to modulate its intrinsic velocity", in contrast to skeletal muscle[44]. It is difficult to evaluate the two possible mechanisms, however, because heart muscle cannot be tetanized and therefore its maximum force and rate of contraction cannot be measured[46,47]. The difficulties associated with the time-dependence of activation do not occur in skeletal muscle and we find that the maximum rate of tension development for a maximum tetanus is not increased at the time the single twitch discloses staircase potentiation (Fig. 2*D* and *E*). Thus the force–velocity relation is not affected by the staircase phenomenon which should essentially involve the intensity of activation of the myofilaments.

In conclusion, the kinetics of contraction can be analysed rather consistently and quantitatively in human muscle *in situ*. Besides their obvious importance in human muscle diseases (unpublished work of J. E. Desmedt and B. Emeryk) such studies are useful because they are concerned with muscles in entirely normal physiological conditions and thus offer a point of view which is complementary to that of *in vitro* biophysics of muscle sub-systems. The present work was prompted by the finding[38] that the twitch time course is shortened, rather than prolonged, in staircase potentiation elicited by 2/sec stimulation. This ruled out the current explanation based on a prolongation of the "active state" decay. On the other hand, the force–velocity relation of the muscle is not modified because the maximum rate of tension development in tetanus is unchanged (Fig. 2*D* and *E*). The staircase phenomenon must therefore depend on an intensification of the twitch "active state", early in the contraction cycle (Fig. 3), and a working hypothesis is proposed. This conclusion is contrary to the current view that the "active state" would be maximum in the single twitch[1], but it is argued that this postulate of Hill's model was not in fact adequately substantiated and can be abandoned on the basis of new evidence.

PLANETARY SCIENCE

Eliminating False Alarms when detecting Seismic Events Automatically

ONE of the principal difficulties of using the full capabilities of a seismic array and a digital computer for the automatic detection of seismic events is the number of false alarms produced by spurious noise spikes on single channels That this is a problem is shown by the fact that the usual dynamic range between the background noise level and saturation is normally in excess of 40 dB Large noise impulses on a single channel will therefore predominate on a phased sum of the array seismometer outputs unless the number of sensors is very large

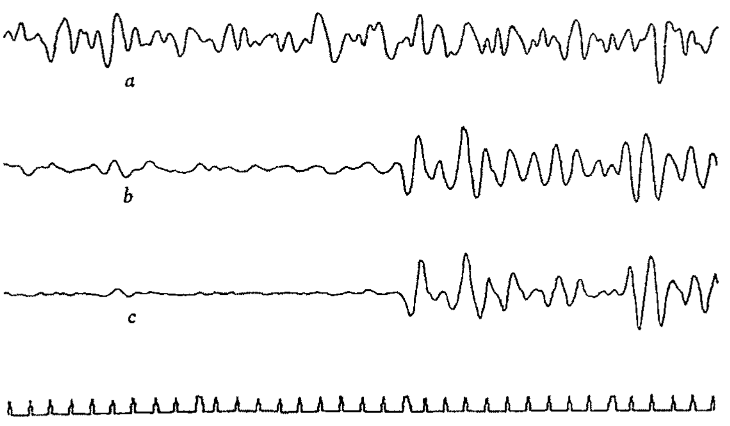

Fig 1 Origin 52 9 S , 28 1 E , depth 33 km, mag 4 7, azimuth 215 8°, J B phase velocity 21 9 km/sec Origin time October 5, 1966, 23 h 23 min 53 2 sec *a*, Single seismometer, *b*, phased sum, *c*, process described in this communication

Various methods of overcoming this problem have been given in the literature Birthill and Whiteway[1], for example, have adopted a correlation and averaging process using two partial sums from the phased array Although an improvement in noise rejection is gained, it is limited by the short duration of the averaging time (because of the small time during which a seismic event is coherent) as well as being very demanding in computer time[2]

I have tried several different techniques in an effort to overcome these deficiencies, and have found one which not only reduces susceptibility to this type of noise but gives evidence of improving the signal to noise ratio as well as the array resolution The particular process which was used is to take the *n*th root of the absolute value of each individual signal, with the original sign preserved before phasing and summation For $n=2$ this corresponds to

$$E_i(t) = \text{signum}\,[S_i(t)+N_i(t)] \times |S_i(t)+N_i(t)|^{\frac{1}{2}}$$

where $S_i(t)$ is the coherent signal component and $N_i(t)$ is the noise output of the ith seismometer at time t If after summation the result is squared, then in the case when $S_i(t) \gg N_i(t)$ this process is identical to the direct summation process, except for a constant factor depending on the number of sensors used

A comparison of this method, using a value of $n=2$, with that of the normal phased summation technique is shown in Fig 1 and reveals a signal to noise ratio improvement for an event which is hidden in the background noise on a single seismometer output A further comparison on two events with similar azimuths and phase velocities (Fig 2) shows an enhancement of the smaller event when the array is correctly phased and greater rejection, particularly in the coda, when the array is phased for the second event

I am not able to give any formal mathematical reason for these results, however, I suggest that the character of seismic background noise is not stationary for

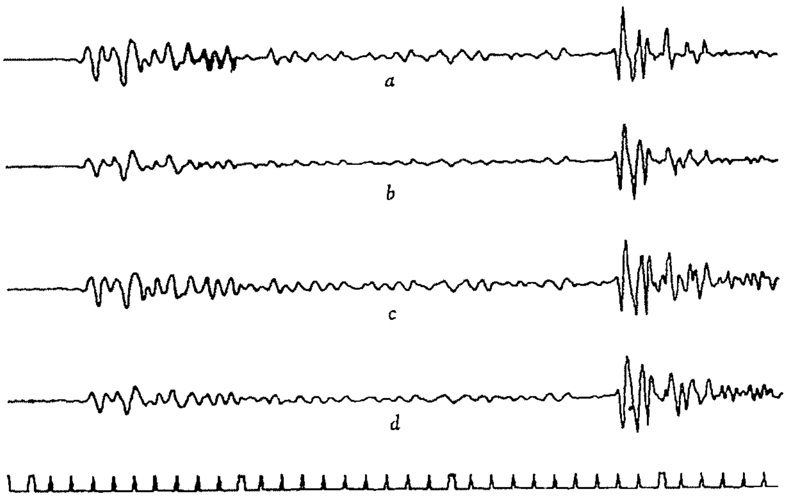

Fig 2 Event 1 origin 15 1 S , 173 5 W , depth 33 km, mag 4 8, azimuth 93 2°, J B phase velocity 14 5 km/sec Origin time October 14, 1966, 2 h 32 min 31 8 sec Event 2 origin 23 2 S , 179 8 W , depth 456 km, mag 4 8, azimuth 102 9°, J B phase velocity 14 0 km/sec Origin time October 14, 1966, 2 h 34 min 34 1 sec *a*, Process described in this communication, array phased to first event and *b* to second event *c*, Normal delay and sum, array phased to first event and *d* to second event

small intervals of time and that my process tends to equalize the variance of this noise.

Palaeomagnetism of a Stratiform Intrusion in the Pensacola Mountains, Antarctica

A LARGE stratiform mass of pyroxene gabbro interlayered with smaller amounts of anorthosite and pyroxenite and capped with granophyre makes up most of the northern ranges of the Pensacola Mountains (Fig 1)[1] These layered rocks are at least 2,000 m thick in both the Dufek Massif and the Forrestal Range, and are believed to belong to a single sheet-like body with an areal extent of at least 8,000 km² The age of the body is not known with certainty, but it intrudes folded rocks as young as Permian (personal communication from J M Schopf) and therefore is probably Mesozoic or younger

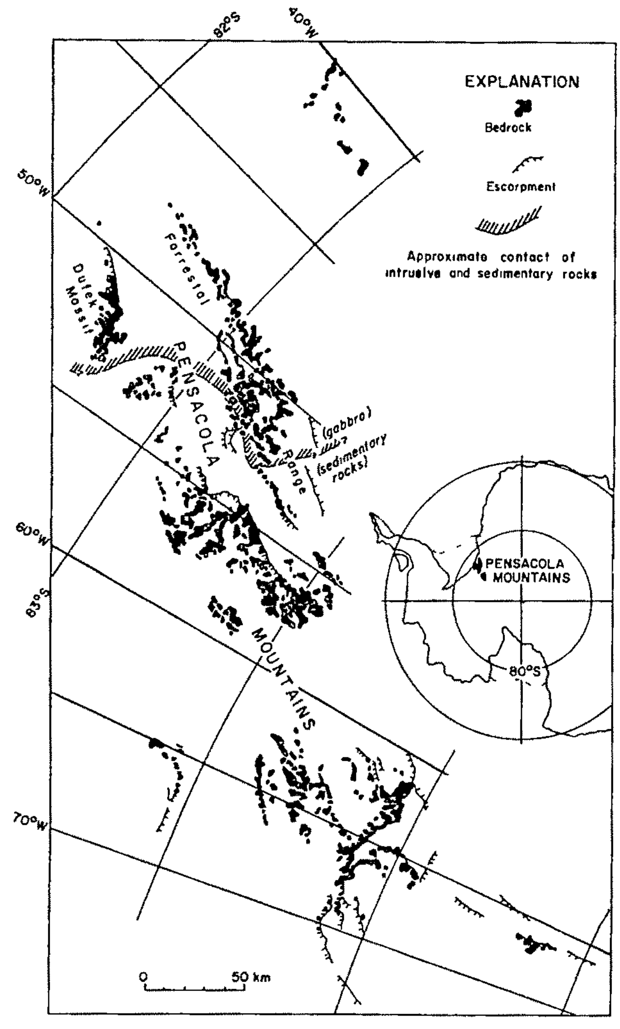

Fig 1 Index map showing the location of the Dufek Massif and the Forrestal Range

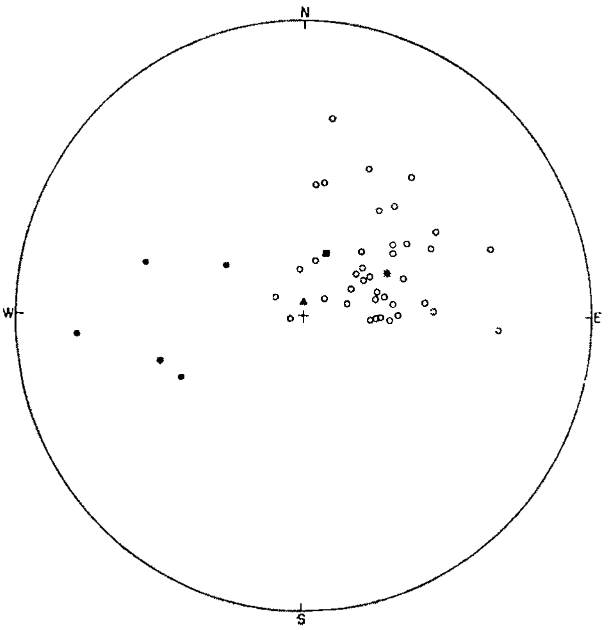

Fig 2 Equal-area projection of site-mean directions of remanent magnetization for the Dufek Massif Open circles are site-mean directions plotted on the upper hemisphere, solid circles are plotted on the lower hemisphere Mean direction for the Dufek Massif (computed after the lower hemisphere points were "reversed" by inversion through the centre of the projection) indicated by * The direction of the present geomagnetic field in the sampling area is shown by the square (upper hemisphere), while the axial dipole direction is shown by the triangle

As a preliminary investigation of the palaeomagnetism of the Dufek Massif, natural remanent magnetization of fifty-seven samples from forty-three sites scattered throughout much of the available exposure has been measured. The results are summarized in Table 1 and Fig 2 Magnetic stability is indicated by divergence of the average direction of magnetization from the direction of the present geomagnetic field and by rough consistency of direction between samples of opposite polarity

Table 1 AVERAGE DIRECTION OF MAGNETIZATION AND PALAEOMAGNETIC POLE POSITION FOR THE DUFEK MASSIF

Direction of magnetization				Palaeomagnetic pole		
N	D	I	k	α_{95}	λ	φ
43	61 5	−63 0	14 7	3 0°	47 5° S	164 0° W

N, No of sites, D, declination east of north, I, inclination positive downward, k, precision parameter (ref 2), α_{95}, radius λ, latitude, and φ, longitude, of the palaeomagnetic pole

To determine the effect of alternating field magnetic cleaning, a suite of twelve specimens was chosen at random and demagnetized in fields ranging up to 300 oersteds Although the directions of individual specimens showed some change during this process (average change < 8°), neither the mean direction of the suite nor the precision of the mean altered to any significant extent

The pole position listed in Table 1 is near, but not in, the cluster of palaeomagnetic poles which have been calculated for rock units assigned to the Ferrar Dolerites of Harrington[3] (see, for example, poles 9 37, 9 38, 9 42 and 9 56 in ref 4) The Ferrar Dolerites are believed to be Jurassic, and the palaeomagnetic data indicate that the gabbros of the Dufek Massif also originated then The slight difference in pole position may indicate that the two are not precisely contemporaneous

The five reversely magnetized sites shown in Fig 2 are located in a definite zone, and similar reverse polarity zones have been encountered in the gabbros of the Forrestal Range This arrangement could be explained by reversal of the Earth's magnetic field during cooling of the stratiform gabbros or by mineralogically controlled self-reversal If the Earth's magnetic field reversed its polarity one or more times while the gabbro body was in the process of cooling through the range of temperatures in which it acquired its magnetization, the result would be a system of polarity zones parallel to the isothermal surfaces in the gabbro On the other hand, polarity zones parallel to compositional layering could arise if (*a*) certain portions of the stratiform complex possess self-reversing properties[5] by virtue of the composition of their iron oxide minerals, and (*b*) these iron oxide minerals vary systematically throughout the complex (share in the cryptic layering[6]) Mineralogical studies are in progress to resolve this question

The gabbros of the Forrestal Range are much more strongly magnetized than those of the Dufek Massif This is shown in Fig 3, where intensity of remanent magnetization is plotted against magnetic susceptibility. Such a diagram brings together the two principal variables controlling total magnetic intensity—specifically those variables which are most closely related to other rock properties[7] Systematic differences in position on such a plot should reflect systematic differences in gross composition, mineralogy, texture or other rock properties In this case it tends to substantiate the view (Ford's unpublished results) that the gabbros of the Forrestal Range represent part of the upper portion of the stratiform complex, while those of the Dufek Massif formed near its base

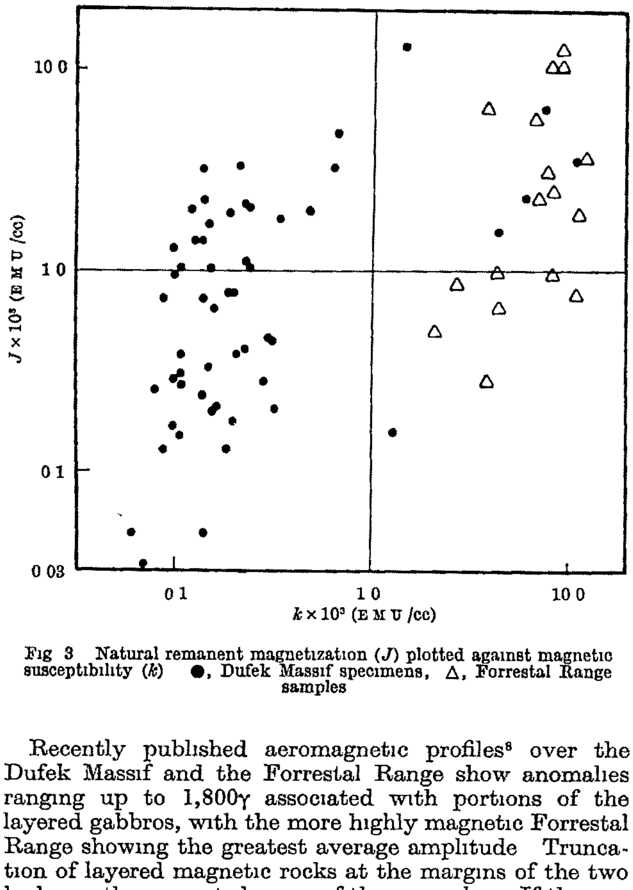

Fig 3 Natural remanent magnetization (*J*) plotted against magnetic susceptibility (*k*) ●, Dufek Massif specimens, △, Forrestal Range samples

Recently published aeromagnetic profiles[8] over the Dufek Massif and the Forrestal Range show anomalies ranging up to 1,800γ associated with portions of the layered gabbros, with the more highly magnetic Forrestal Range showing the greatest average amplitude Truncation of layered magnetic rocks at the margins of the two bodies is the suggested cause of the anomalies If the size and geometrical configuration of the polarity zones are favourable, reversals of polarity could make an important contribution to these anomalies by producing a source of strong magnetic contrast within the gabbro bodies In the Dufek Massif, where the ratio of remanent to induced magnetization is almost uniformly high, this factor should be especially important

Genesis of Concordant Deposits of Base Metal Sulphides: an Experimental Approach

Despite the great economic importance of the stratigraphically concordant massive sulphide deposits which occur in regionally metamorphosed rocks of pre-Cambrian to Palaeozoic ages in all continents, little is known of their origin Writers on these deposits, which include those of Mount Isa[1], Broken Hill, the Scandinavian Caledonides[2], the Bathurst–Newcastle area[3] and the Rhodesian Copperbelt, have tended to accept one of two apparently conflicting views Some maintain that the deposits are syngenetic[4], representing original sedimentary or volcanic sulphides, while others consider them to be epigenetic[5], and formed by precipitation from hydrothermal solutions of igneous or metamorphic origin

In a study of the Caledonian chalcopyrite–pyrite–arsenopyrite veins of the English Lake District, one of us concluded[6] that the mineralizing solutions were derived from the dehydration of rocks undergoing metamorphism in the deeper levels of the Caledonian geosyncline Significant metal contents have since been noted in brines of metamorphic origin from the Salton Sea area in California[7], and pockets of hot zinc-rich solutions of presumed volcanic origin have been located in the Red Sea[8] Prolonged contact between such solutions and pyrite deposits of sedimentary or volcanic origin could well produce massive sulphide deposits with features characteristic of both syngenetic and epigenetic origins, and so we have conducted experiments to determine the effectiveness of pyrite as a scavenger of base metals, and the extent to which pyrite deposits would be dispersed by metamorphism

The scavenging properties of pyrite were tested by holding mixtures of pyrite and pyroxenite, pyrite and carbonaceous shale, and pyrite and synthetic limestone at 500°–600° C, 1–2 kbars for 10 days, in the presence of appropriate mineralizers (Table 1) The pyrite was

Table 1 RUN CONDITIONS

Run No	Reactants	Time (days)	T (° C)	Pressure (kbars)	Mineralizer
3	60% pyroxenite–40% pyrite	10	600	2 0	50% HCl
4	70% limestone–30% pyrite	10	500	1 0	4M–NH_4Cl
5	70% shale–30% pyrite	10	600	2 0	50% HCl

Table 2 TRACE ELEMENT CONTENTS OF REACTANTS (P P M)

Sample	Co	Ni	Cu	Zn	Pb
Pyrite	100	150	300	250	850
Black shale	75	200	250	250	500
Pyroxenite	80	800	100	150	400
Synthetic limestone	500	500	500	500	500

extracted by grinding the recrystallized charge to 150 mesh, followed by flotation using a collector of potassium amyl xanthate, with boral as the frother Sodium silicate was used as a depressant for calcite in the runs containing synthetic limestone Pyrite fractions of high purity were obtained by this method, and analysed by X-ray fluorescence (for cobalt, nickel, zinc and lead) and colorimetric methods (copper), with the results shown in Table 3 The experimental enrichment factors were then recalculated to eliminate the effects of variations in the initial trace element concentrations and rock to pyrite ratios (Table 4)

Table 3 EXPERIMENTALLY DETERMINED ENRICHMENT FACTORS (FINAL/INITIAL CONCENTRATION) FOR THE PYRITE FRACTION

Run No	Rock type	Co	Ni	Cu	Zn	Pb
3	Pyroxenite	2 0	2 0	1 3	1 4	1 1
4	Limestone	6 0	3 7	1 7	1 2	1 5
5	Black shale	1 5	1 7	1 5	1 4	1 0

Microscopic examination of the products indicated that reaction was incomplete, and these enrichment factors are therefore lower than those which would be observed at equilibrium The relative concentrations in this Table are considerably more accurate than the absolute values in Table 2

Table 4 ADJUSTED ENRICHMENT FACTORS

Run No	Rock type	Co	Ni	Cu	Zn	Pb
3	Pyroxenite	12 3	4 3	3 3	1 7	1 3
4	Limestone	8 0	5 7	3 1	1 5	2 4
5	Black shale	2 0	2 2	2 0	1 7	1 0

The adjusted enrichment factor is $(p_f/r_f)/(p_i/r_i)$, where p_i, p_f are the initial and final concentrations of a given element in the pyrite fraction, and r^i, r_f are the initial and final concentrations in the rock fraction

Cobalt and nickel, which form pyrite-type sulphides, and copper, which is moderately soluble in the pyrite structure, were strongly fractionated

$$M^{2+} + \text{excess } FeS_2 \rightleftharpoons (Fe,M)S_2 \text{ solid solution} + Fe^{2+}$$

but lead and zinc, which have very limited solubility in pyrite, showed much weaker initial fractionation, possibly involving reactions such as

$$Zn^{2+} + 2Fe^{2+} + FeS_2 \rightleftharpoons 2(Fe,Zn)S \text{ solid solution} + 2Fe^{3+}$$
$$Pb^{2+} + 2Fe^{2+} + FeS_2 \rightleftharpoons PbS + FeS + 2Fe^{3+}$$

In the experiments on dispersion, finely ground mixtures of pyrite and rock powder were held at 600° C, 2 5 kbars for 12 days in the presence of mineralizers which included 4 molar ammonium chloride, 50 per cent hydrochloric acid, saturated sodium chloride solution and distilled water Recrystallization of pyrite was effected in all runs except those containing distilled water, but there was no detectable migration of pyrite along the temperature gradient of about 10° C/cm maintained in the gold sample capsules In similar conditions, but with no rock powder to hinder convection, pyrite was rapidly transported to the cold end of the tube It is concluded that all the elements studied will be concentrated in the pyrite bodies during the metamorphism of a mixed pyrite–silicate sequence, the final concentration in the sulphide body depending on the fractionation constants under the pressure–temperature–composition conditions of metamorphism, the initial trace element contents in the pyrite and its country-rock, the effective rock to pyrite ratio, and the time available for reaction

It also seems that pyrite deposits in a compact rock mass would not suffer significant dispersion during metamorphism, unless there was a flow of metamorphic fluid through the pyrite-bearing rock Dispersion, however, may become more important at high metamorphic grades, when solubilities increase with pressure and temperature At low grades any such tendency will probably be outweighed by mechanical concentration of the easily deformed sulphides in regions of low stress, such as fold crests

The experimental results thus support our initial hypothesis that the mineralogy and structure of some syngenetic pyrite bodies could be modified so profoundly during subsequent diagenesis, metasomatism and metamorphism as to render meaningless the distinction between "syngenetic" and "epigenetic" or "hydrothermal" deposits We should instead expect to find all gradations between the two extremes

Accepting this as a working hypothesis, two economically important results follow First, the search for further ore deposits of this type should be concentrated in areas of low to medium grade regional metamorphism (low dispersion), in which strongly deformed country rocks containing high initial concentrations of thiophile elements (mechanical and chemical concentration) are associated with pyrite bodies Second, the possibility of tapping the metamorphic fluids themselves as sources of base metals should not be overlooked, for fluids of the Salton Sea[7] and Red Sea[8] types may well occur within reach of the surface in many of the younger volcanic and orogenic belts of the world

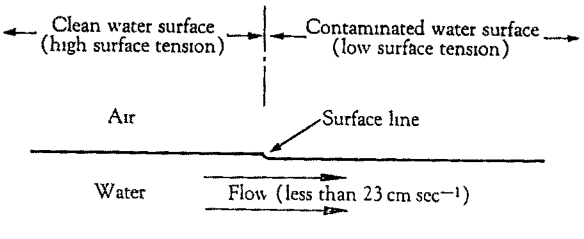
PHYSICS

Existence of a Surface Tension Discontinuity at a Liquid Free Surface

EXPERIMENTS have shown that, in certain conditions, a free water surface can exist in equilibrium with different values of surface tension in different regions So far, only two such regions have been distinguished in any one water surface and their common boundary can be seen clearly in reflected light, after a little practice, as an unbroken sinuous line One region appears to be chemically clean while the other is obviously contaminated with a surface film This situation remains stable only if the water has a low velocity (less than 23 cm/sec) which acts—see Fig 1—in such a way that the contaminated surface region is "contained" by the shear stresses set up by the flow against the underside of the surface film If the water



Clean water surface (high surface tension)
Contaminated water surface (low surface tension)
Air
Surface line
Water
Flow (less than 23 cm sec⁻¹)

Fig 1 Water surface profile perpendicular to surface line

velocity dies away the contaminated zone spreads out to cover the whole water surface It is the line marking this boundary which is the subject of the present study and it will be referred to here as the "surface line" This topic is of interest in chemical engineering where the results might be used to control the separation of minerals and other compounds by surface flotation

A reflected light Schlieren system was developed for this study from an earlier form of the apparatus described elsewhere[1] Fig 2 shows the lay-out of the optical components of the system in relation to the "hydraulic" apparatus The water tank used had a free surface measuring 60 × 90 cm with a depth of 60 cm Untreated mains water was introduced through a system of baffles and screens, covering the full width of the tank, which was designed to ensure two-dimensional circulation of the water in the tank proper, as indicated in Fig 2 When steady conditions had been established, water left the tank by a full width sharp edged weir, running the full width of the tank, placed at the opposite end to the inlet

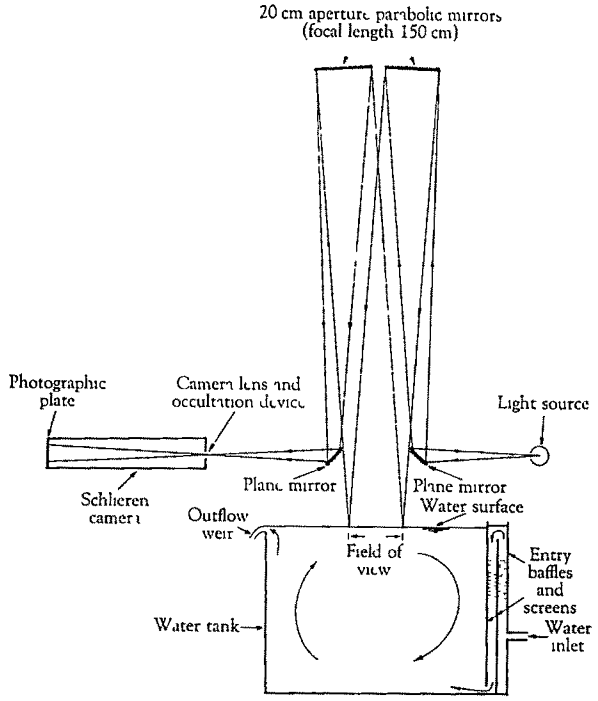


Fig 2 Experimental apparatus shown in elevation

The conditions near the free surface were similar to those shown in Fig 1 Water moved slowly from left to right, the surface contamination being trapped by the inlet baffles at the right, the free surface overflow at the left ensured that a clean water surface was maintained in this region by the rising current there

Before any measurements were made it was apparent that the "strength" of the surface line (in the visual sense) was dependent to some extent on the degree of initial cleanliness of the water surface The inevitable contamination from the atmosphere of the laboratory, however, ensured that the line could always be detected after a brief search The position of the line was variable and depended on the water velocities and the surface contamination level The optical apparatus was arranged on a rigid framework that could be traversed as a whole relative to the water tank so that the surface line once detected could be "moved" into the field of view if necessary The two 20 cm parabolic mirrors gave a parallel beam of light that was reflected at the water surface with an incidence angle of 5° This was as close to normal reflexion as could be obtained and gave a slightly elliptical field of view (20 1 × 20 0 cm) If the angle of incidence became large (say, greater than 8°), optical and geometrical distortions became significant

The optical system, which consisted of plane and parabolic face-silvered mirrors, gave an image of the point light source close to the lens and on the axis of the Schlieren camera This image was small (slightly larger than the light source) only when the reflecting water surface was plane, any distortion of the water surface in the field of view partially defocused the image It is this effect which was used in combination with a suitable occultation device (Fig 3) to give a Schlieren image of the water surface on the camera plate The camera lens was not essential, but its use improved the quality of the final image in a system where small optical imperfections were present

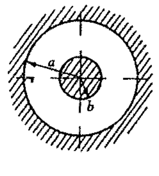

Fig 3 Occultation device used in all experiments Light accepted falling in annulus $b < \text{radius} < a$

Fig 4 shows a Schlieren photograph of the surface line for which the occultation device was set with a narrow acceptance annulus In these conditions two approximately equidistant lines appeared, one brighter than the other This showed that there existed two points of known water surface slope on any perpendicular to the surface line By taking a series of photographs while systematically varying the dimensions of the acceptance annulus it was possible to build up quantitative data on the surface line The phenomenon was unsteady in that the spacing between the two lines on the plate in Fig 4 was seen to vary slightly both with distance and time. The space variable could be eliminated to some degree by averaging a number of values taken from each photograph and this was done, but the time variable was more difficult to remove In the current tests it was partially dealt with by curve smoothing at a later stage of the analysis

The difficulty of relating results from the individual photographs in a series was overcome by fixing one of the acceptance annulus dimensions for that series (either a or b) The relationship between the radius of this annulus and the water surface slope was established by direct calibration, an optical flat mounted on a tilting stage being substituted for the water surface The sensitivity of the apparatus was found to correspond to a water surface slope of 0 00277 radians for each mm of the annulus radius. It can be seen from this that the annulus being of finite thickness will accept light from water surface slopes lying

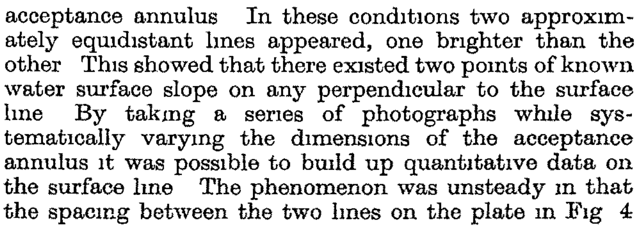

Fig 4 Schlieren photograph of surface line ($a = 12$ mm, $b = 10$ mm).

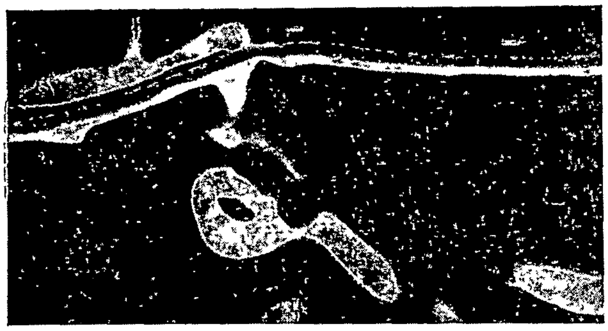

Fig 5. Schlieren photograph of surface line (test *C*–4)

within a certain range It is therefore possible by using wider annuli and by measuring the widths as well as the separation of the photographic traces to build up more complete data of the surface line Three such series were carried out (tests *A*, *B* and *C*) from which Fig 5 is an example Table 1 gives the dimensions of the acceptance annuli used in these tests Because in each test one dimension remains constant it was possible to check the amount of time variation present It was also possible to plot a graph of water surface slope, dz/dx, against perpendicular horizontal distance, x, and to include results from the four photographs in each test on one graph A smooth curve was drawn through these points and numerical integration of this curve gave the mean profile across the line (z—x relationship) These are shown plotted in Fig 6 It must be remembered that the slopes of these profiles and therefore also the curvatures are distorted by the × 25 exaggeration of the vertical scale In spite of this it is clear that the convex (upwards) portion of each profile has a much smaller radius of curvature than the concave part This result corresponds to the point mentioned, that of the two lines shown in Fig 4—and on all such photographs—the upstream trace is always weaker than the other one

Table 1. VALUES OF ACCEPTANCE ANNULI DIMENSIONS (mm) CORRESPONDING TO RESULTS SHOWN IN FIG 6

Test	Annulus radius	1	2	3	4
A	*a*	15 0	15 0	15 0	15 0
	b	4 5	6 0	8 0	10 0
B	*a*	12 5	12 5	12 5	12 5
	b	4 5	6 0	8 0	10 0
C	*a*	4 5	7 0	10 0	12 5
	b	3 5	3 5	3 5	3 5

The interpretation of the slope data to give profiles of the type shown in Fig 6 was assisted by a simple knife-edge test that showed that all water surface slopes attributable to the surface line face the same way It followed from this that the surface line must have a monoclinal step profile rather than that of a solitary wave or cusp The height of this step was obtained from the numerical integration process and was for tests *A*, *B* and *C*, 0 157, 0 183 and 0 185 mm, respectively Mean flow conditions for these three tests—discharge, water level and mean velocities—were the same, the only uncontrolled variable was the surface tension on the contaminated (lower) side of the line.

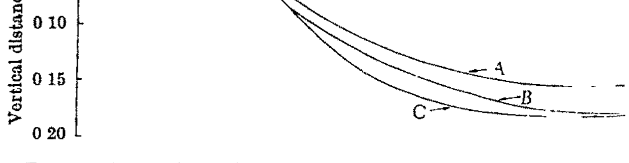

Fig 6 Mean water surface profile perpendicular to the surface line for three tests (vertical scale exaggerated × 25)

In the experiments described, the surface line clearly defined the edge of a contaminated portion of the water surface From this it was suggested that it marked a change in the surface tension value of the free surface and attempts were made to measure this on either side of the line Such measurements were difficult because it was essential that they did not interfere with the surface film formed by the contamination The capillary wave method promises to give the best results but so far has not yielded any reliable data

Observation of this surface film showed that it possessed only second order random velocities and that its mean velocity in the direction of flow (see Fig 1) was zero There must therefore be a boundary layer in the fluid below the film which exerts a shear stress against the underside of the film, acting in the direction of flow It seems probable that this shear stress provides the mechanism for balancing the unequal horizontal surface tension forces on either side of the line, but it also follows that there will be no sharp change in surface tension value at the line

The change in water level measured at the surface line introduces small out of balance hydrostatic pressure forces which cannot readily be explained by hydrodynamic reasoning It is hoped that any relationship between these and surface tension values will be revealed by further experiments in which it is planned to vary the surface tension values systematically while making measurements of these and the corresponding differences in water surface elevation at the line

I thank the Queen's University of Belfast for laboratory facilities and equipment and Professor T. M Charlton for his help and encouragement I also thank the Laboratoires de Mécanique des Fluides of the University of Grenoble for facilities

Wavelengths and Relative A-Coefficients for the Forbidden Lines of Atomic Sulphur

THE multipole lines from atomic sulphur are of considerable astrophysical interest Moreover, a direct measurement of their wavelength is the best and most direct method of fixing the positions of the metastable levels involved Furthermore, a measurement of the relative intensity of magnetic dipole and electric quadrupole lines from the same upper level gives the relative transition probability, which is a valuable check on the theoretical predictions

In an earlier note[1] we reported the first laboratory excitation of the forbidden lines of SI and gave the approximate wavelengths This communication presents the results of relative intensity and accurate wavelength measurements on these lines

The lines were excited in a high voltage a c discharge through a π-shaped tube 100 cm long and 3 cm in diameter with tungsten electrodes in the side arms The tube was filled with krypton to a pressure of a few mm of mercury after some sulphur had been distilled in under vacuum After running for a time impurities such as carbon monoxide were cleaned up Krypton was used as the filler gas rather then xenon (which we used before), so that additional population of the $^1S_0$ state would result through the resonance reaction

$$\mathrm{Kr}(^3P_2)+\mathrm{S}_2(^3\Sigma)\rightarrow \mathrm{S}(^1S_0)+\mathrm{S}(^1S_0)+\mathrm{Kr}(^1S_0)$$

This approximately doubled the intensity of the forbidden lines

Optimum conditions for the emission of the lines were achieved when the tube was surrounded by an oven kept at 45° C and the tube current was 12 mamp

For the wavelength measurements the discharge was observed end on through an optically flat window using a 3 5 m Fastie–Ebert echelle grating spectrograph The $^1S_0$–$^3P_1$ transition was observed in the thirteenth order with a plate factor of 0 33 Å/mm and the $^1S_0$–$^1D_2$ transition was observed in the eighth order where the plate factor was 0 49 Å/mm The effective aperture of the instrument was approximately *f*/30 and it was kept in a constant temperature room to minimize shifts during the long exposures which were necessary Kodak II *L* and *Oa F* plates were used to record the lines Krypton, impurity xenon and allowed sulphur lines were used to provide reference wavelengths Using these, the wavelength of the $^1S_0$–$^3P_1$ transition was found to be 4589 261 ± 0 007 Å and that of the $^1S_0$–$^1D_2$ transition 7725 04 ± 0 01 Å

Toresson[2] has made measurements on the vacuum ultraviolet spectrum of SI and from these has fixed the term values of the low lying levels including the $^1S_0$ and $^1D_2$ metastable levels Using his values for these levels, one can compute the wavelengths of the $^1S_0$–$^3P_1$ and $^1S_0$–$^1D_2$ transitions as 4589 61 Å and 7725 8 Å, which are in disagreement with the values given here Toresson's positioning of both the $^1S_0$ and $^1D_2$ levels is, however, based on single transitions in the vacuum ultraviolet and may therefore be liable to some error On the other hand, his values for the $^3P_{0,\,1,\,2}$ states are based on a considerable number of transitions and can therefore be regarded as more accurate Assuming his values for the $^3P_{0,\,1,\,2}$ levels, and using our measured wavelengths as already given, a revised term system can be drawn up as given in Table 1 Also shown are the values given by Moore[3]

Table 1 REVISED SI LEVELS

Term symbol	Moore	E cm^{-1} Toresson	Present results
$3s^2\ 3p^4\ ^3P_2$	0 00	0 00	0 00
$^3P_1$	396 8	395 56	395 56
$^3P_0$	573 6	573 19	573 19
$^1D_2$	9,239 0	9,237 76	9,238 10
$^1S_0$	22,181 4	22,177 82	22,179 46

Bowen[4] has observed a faint line at 7726 5 ± 0 3 Å on one spectrum from a nebula and has suggested that it might be caused by the $^1S_0$–$^1D_2$ transition This now seems unlikely in the light of the present results Swings (personal communication) has observed a line in the solar spectrum at 7725 04 ± 0 01 Å in agreement with our observed value and which, from width considerations, could be caused by a forbidden transition of SI

Measurements of relative intensity were made on the two lines with a Jarrell-Ash 0 5 m Ebert grating spectrograph and an EMI 9558 *QB* photomultiplier The relative quantum efficiency of the detecting system in the two wavelength regions was obtained using a tungsten filament lamp calibrated by the National Physical Laboratory A value of 5 1 ± 0 7 was obtained for the ratio of the A-coefficients which compares with Czyzak and Krueger's[5] theoretical value of 5 09 This agreement between theory and experiment is better than that reported earlier[6] for the equivalent lines of atomic oxygen.

We thank Professor D J Bradley of this department for putting his high resolution spectrograph at our disposal One of us (J A K) wishes to acknowledge the award of a postgraduate studentship from the Government of Northern Ireland, Ministry of Education.

THE SOLID STATE

Crystal Structure of Ethylenebidiguanide Silver (III) Nitrate

WHILE trying to prepare co-ordination compounds of ethylenebidiguanine with bivalent silver analogous to Cu(II) and Ni(II) by oxidation of a silver salt by sodium persulphate, Ray and Ghosh[1] found that a complex compound was formed in which silver exhibited an oxidation state of three instead of the expected two Tervalent silver is isoelectronic with Pd(II) Ray and Ghosh proved the trivalency of silver by showing experimentally the diamagnetic character of silver (III) ethylenebidiguanide complex salts, and on the basis of this evidence they proposed a square-planer configuration (dsp^2 hybridization) for silver in these compounds, with the silver coordinated to four nitrogen atoms of the ligand I have analysed the crystal structure of silver ethylenebidiguanide nitrate to confirm this proposal, and also because complete crystallographic work on a trivalent silver compound has not yet been reported

Silver ethylenebidiguanide nitrate crystallizes into orange red needles, elongated in the (001) direction Preliminary work carried out on a *GE-XRD*-6 diffractometer established that the crystals belong to a triclinic system and the centrosymmetric space group $P\bar{1}$ was assigned This was consistent with the subsequent structure analysis The cell dimensions are $a=8\ 283\pm0\ 004$ Å, $b=12\ 748\pm0\ 004$ Å, $c=8\ 530\pm0\ 004$ Å, $\alpha=104\ 12°$, $\beta=96\ 64°$, $\gamma=99\ 73°$, $D_{\mathrm{obs}}=2\ 03$ g cm^{-3}, $D_{\mathrm{calc}}=2\ 03$ g cm^{-3}, $Z=2$.

Three-dimensional intensities were collected on a *GE-XRD*-6 diffractometer with a single crystal orienter using copper $K\alpha$ radiation, cobalt–nickel balanced Ross filters and a scintillation counter A needle shaped crystal (0 1 × 0 1 × 0 3 mm) was used The 2,555 independent reflexions within a range of $2\theta=0°$–$120°$ were examined,

* The coefficients of *P*, *Q* and *R* are the direction cosines of the normal to the plane with respect to the axes $a(a\times b)\times a$ and $(a\times b)$, respectively

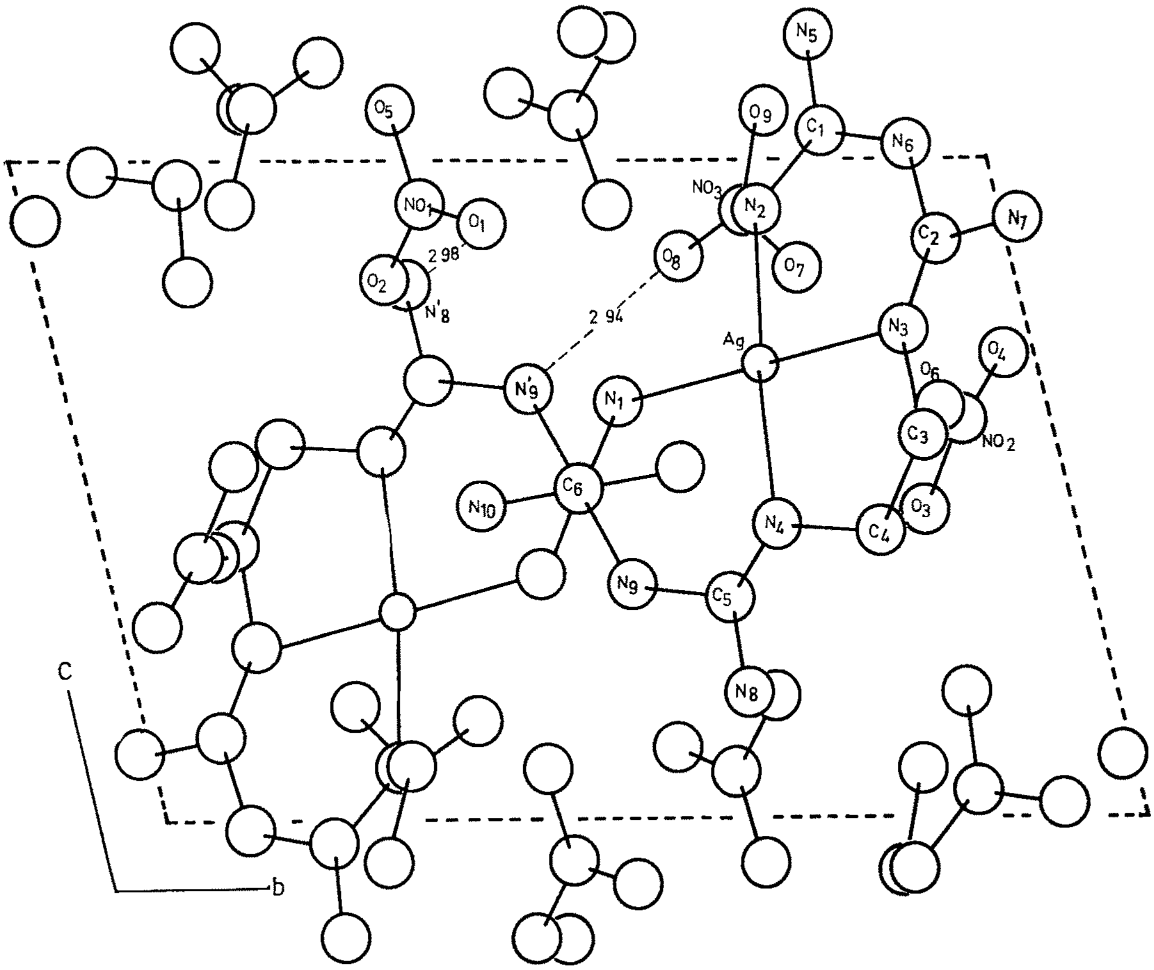

Fig. 1. A diagrammatic representation of the structure projected down the *a* axis

of these ninety-seven were too weak to be measured. The stationary crystal–stationary counter technique was used for the intensity measurements. Absorption and the usual $1/LP$ corrections were applied.

To solve the structure, the co-ordinates of silver were obtained from a 3-D Patterson synthesis. A silver-phased 3-D Fourier synthesis then carried out revealed the positions of all the light atoms. The structure was then refined in three cycles by the least-squares method with individual anisotropic temperature factors and a block diagonal approximation. The final agreement index R was 0.105 for all observed reflexions.

A diagrammatic representation of the structure, along the *a* axis, is shown in Fig. 1, and the various bond lengths and angles are illustrated in Fig. 2. The estimated standard deviations in the various bond lengths and angles are Ag—N = 0.012 Å, C—N, C—C and N—O are 0.02 Å and 0.8° for various angles. A molecule of ethylenebidiguanine acts as a tetradentate ligand and forms two co-ordinate and two covalent bonds through the four nitrogen atoms. This results in one five-membered and two six-membered rings forming a chelate compound. Table 1 shows the results of calculations to test the planarity of these rings.

Table 1 shows that the five-membered and the two six-membered rings are planar. The angle between plane 2 and 3 is 138.3°, between 2 and 4 is 146.4° and between 3 and 4 is 150.8°. So the molecule is not planar as in the analogous copper complex[4] and as expected from the previous chemical work[1]. The non-planarity of the three rings results in the distortion of the square-planar configuration of silver as can be seen in Table 1.

All three independent nitrate ions are planar and their dimensions have normal values. The two nitrate ions are hydrogen bonded to the silver complex ion (Fig. 1).

Crystal Structure and the Lower Phase Transition in Solid Deuterium Bromide

The study of crystal structure and phase transition in hydrogen and deuterium chlorides reported in two previous communications[1,2] has now been extended to cover the temperature range 4°–150° K A comprehensive communication reporting on these investigations is in preparation Meanwhile, the structure investigations are continuing to cover the remaining hydrogen and deuterium halides

It has been known from specific heat measurements[3,4] that solid deuterium bromide undergoes two second-order phase transitions, both spread over temperature ranges of several degrees (lambda transitions) The lower transition is completed at about 93 5° K, the upper transition at about 120 3° K This behaviour is markedly different from that of hydrogen bromide[5], which has three second order transitions in the solid state The two upper transitions are very close to one another, the one being completed at about 113 6° K, the other at about 116 9° K

X-ray powder photographs taken of solid hydrogen bromide by different researchers have been interpreted differently Ruhemann and Simon[6] suggested that hydrogen bromide has a face-centred orthorhombic lattice over the entire solid range Natta[7], however, claimed that in addition to the face-centred orthorhombic phase there is also a face-centred cubic phase restricted to a narrow temperature range between the two upper phase transitions We think that both conclusions were erroneous The suggestion of Ruhemann and Simon was based on the presence of a few persistent low angle lines which were probably caused by impurities On the other hand, Natta's claim regarding the temperature range of the face-centred cubic phase can be attributed to the large uncertainty of his temperature estimates and to his apparent lack of X-ray data above 120° K These early X-ray studies revealed only the location of the bromine atoms but gave no clue regarding the location of the hydrogen atoms

Subsequent experimental investigations using dielectric constant[8–11], optical[12], spectroscopic[13–24], nuclear magnetic resonance[25], and inelastic neutron scattering[26] techniques led to the conclusion that below the lowest transition region, both hydrogen bromide and deuterium bromide have an ordered structure composed of hydrogen-bonded zigzag chains Various structural models of this type were put forward, those consisting of antiparallel chains being more favoured, following earlier theoretical predictions The higher phases were thought to be associated with various kinds of disorder in the orientation of the molecules Though the type of orientational disorder could not be specified unambiguously, it was generally agreed that the molecules could not rotate freely in any of the solid phases No suggestion has been put forward to account for the two upper transitions in hydrogen bromide

To resolve these ambiguities, the crystal structure of solid deuterium bromide was investigated by X-ray and neutron powder diffraction methods using the experimental techniques described in previous communications[1,2] X-ray powder photographs taken at 86°, 92°, 95°, 107° and 118° K showed that the bromine atoms form a face-centred orthorhombic lattice over the entire 86° K to 118° K temperature range, that is, right up to the end of the upper transition region The volume of the face-centred orthorhombic unit cell increases with the temperature over the entire range investigated The total volume increase over the lower transition region (stretching from about 74° K to about 93 5° K) is approximately 1 4 per cent and it is strongly anisotropic only the a and b parameters increase, the c parameter decreases A conspicuous feature of all X-ray powder photographs taken in the 86°–118° K range is the blurring of the medium and high angle lines They are markedly different in appearance from the much sharper X-ray powder lines recorded above the upper transition region

The unit cells of deuterium bromide derived from the neutron powder diffraction patterns recorded at 84° K and 107° K agreed in size with the face-centred orthorhombic unit cells derived from the X-ray powder photographs, but their symmetries were different at both temperatures The space group of deuterium bromide at 84° K was found to be $Bb2_1m$—the same as that of the ordered low temperature phase of deuterium chloride[1,2] On the other hand, the space group of deuterium bromide at 107° K was found to be $Bbcm$ Neutron diffraction patterns recorded at 88° K and at 91° K showed a gradual change from space group $Bb2_1m$ to space group $Bbcm$ This was particularly conspicuous in the case of the (101) peak the intensity of which decreased rapidly with increasing temperature until it disappeared altogether above the lower transition region This is illustrated in Fig 1 where the absolute values of the $F(101)$ and $F(111)$ structure factors observed at four different temperatures are plotted The specific heat of deuterium bromide[3,4] over the lower temperature region is shown in Fig 2

These findings can be interpreted as follows Deuterium bromide below the lower transition region is isomorphous with the low temperature phase of deuterium chloride[1,2], that is, it has an ordered crystal structure composed of parallel plane zigzag chains The results of the least-squares refinement of this model are summarized in Table 1

The crystal structure of deuterium bromide in the "middle phase" lying between the two transition regions is disordered The disorder is orientational each molecule has two equilibrium orientations, one is the same as in the ordered phase, the other opposite to it The unit cell of this disordered middle phase is shown in Fig 3 The results of the least-squares refinement of this model are summarized in Table 2

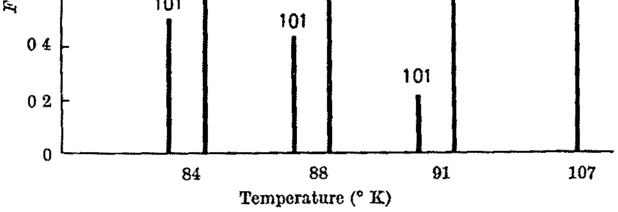

Fig 1 Plot of the absolute values of $F(101)$ and $F(111)$ structure factors for deuterium bromide observed at 84° K, 88° K, 91° K and 107° K

R factor after six cycles of isotropic refinement $R_1=4.5$ per cent

Table 2. STRUCTURAL DATA OF DEUTERIUM BROMIDE AT 107° K

Lattice parameters

$a=5.559\pm0.005$ Å, $b=5.649\pm0.005$, $c=6.095\pm0.005$ Å

Space group *Bbcm*, No. of molecules in the unit cell 4

Fractional positional parameters of the atoms

	x	*y*	*z*
Deuterium	−0.172 ± 0.006	+0.177 ± 0.004	0
Bromine	0	0	0

Isotropic temperature factors of the atoms (*B* in Å^2)

Deuterium	8.4 ± 0.8
Bromine	4.4 ± 0.8

D–Br bond length 1.38 ± 0.04 Å
Br–Br–Br angle in the chain 90° 56′ ± 4′
R factor after six cycles of anisotropic refinement $R_1=6.1$ per cent

Because of the small difference between the lattice parameters *a* and *b* in the middle phase, the powder peaks considerably overlap in this region. This explains the somewhat higher value of the *R* factor and the great uncertainties of the temperature factors. The positional parameters, however, are expected to be accurate within the limits stated.

In the lower transition region, deuterium bromide forms a mixed crystal the two components of which are the ordered low temperature and the disordered middle phases. The composition of the mixed crystal varies continuously with temperature and the two components are miscible in all proportions. In other words, the crystal structure of deuterium bromide in the lower transition region is a substitutional solid solution of two "types" of deuterium bromide molecules. One type has a single equilibrium orientation, characteristic of the ordered low temperature phase, the other type has two equilibrium orientations, characteristic of the disordered middle phase. The two types of molecules form a continuous series of solid solutions, which follow Vegard's law and whose composition varies continuously with temperature. The volume requirements of the two types of molecules differ by less than 1.4 per cent which does not prevent the formation of an apparently homogeneous phase over the lower transition region; nevertheless it is sufficient to give rise to mechanical strains in the specimen. This explains the blurred character of the X-ray powder lines in this region. It also suggests that the distribution of the two types of molecules among equivalent lattice sites is not entirely random. It is more likely that molecules of the same type form small domains dispersed over the entire specimen.

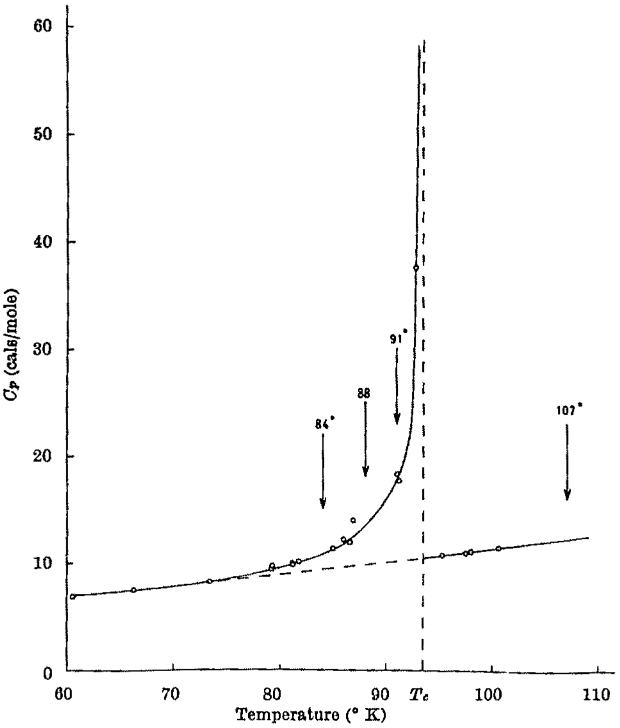

Fig. 2. The specific heat of deuterium bromide over the temperature range 60° K to 100° K. The arrows indicate the temperatures at which the structure factors in Fig. 1 were recorded. The vertical dashed line marks the end of the lower transition region. The slightly sloping dashed line gives an idea of the temperature range in which the specific heat is "anomalously" high.

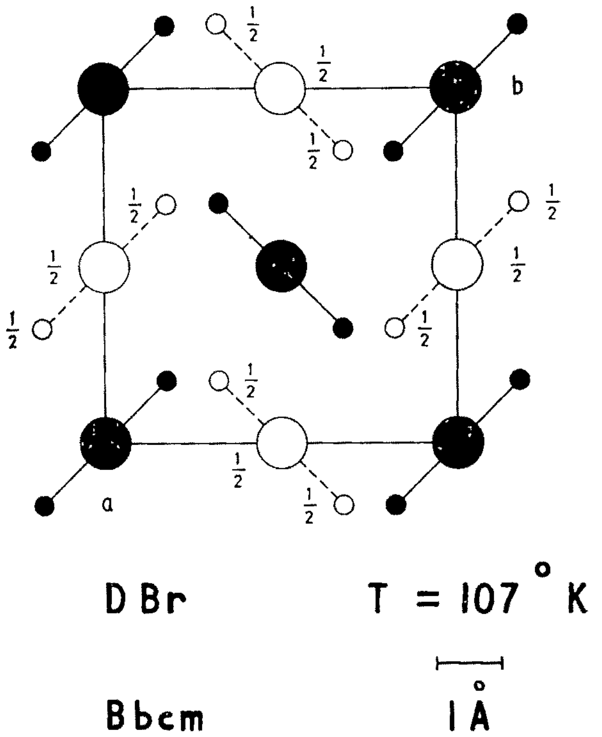

Fig. 3. The unit cell of the disordered middle phase. ●, The equilibrium position of bromine atoms in the plane of the page, ○, the equilibrium position of bromine atoms at $z=c/2$, •, the equilibrium position of deuterium atoms in the plane of the page, and ∘, the equilibrium position of deuterium atoms at $z=c/2$.

Because in the disordered middle phase $F(101)=0$, the composition of the solid solution can be estimated by taking the ratio of the absolute value of $F(101)$ observed at a given temperature to the absolute value of $F(101)$ calculated for the ordered low temperature phase. This ratio is expected to give the ratio of the number of deuterium bromide molecules in the ordered low temperature phase to the total number of deuterium bromide molecules in the specimen. The values of this ratio at 84°, 88°, 91° and 107° K, expressed in percentages, are shown in Fig. 4. The dashed curve in Fig. 4 should only be considered as indicative of the composition of the solid solution in the lower transition region for two reasons. First, the number of observations is too small, second, deuterium bromide is expected to show thermal hysteresis in the lower transition region similar to that observed in hydrogen bromide[27]. Thus the composition of the solid solution may depend not only on the temperature but also on the direction in which the lower transition region is traversed. The data in Fig. 4 were obtained when the region was traversed in the direction of increasing temperature. It is interesting to compare the lower transition of deuterium bromide with the single transition in deuterium

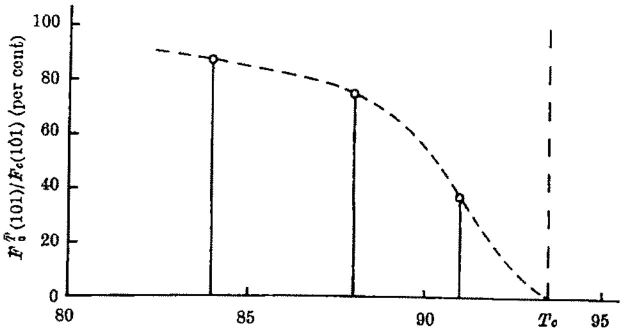

Fig 4 The ratio of the absolute value of $F(101)$ observed at a given temperature to the absolute value of $F(101)$ calculated for the ordered low temperature phase The ratio should give the ratio of the number of deuterium bromide molecules in the ordered low temperature phase to the number of deuterium bromide molecules in the specimen The ratio is expressed as a percentage Temperatures 84° K, 88° K, 91° K and 107° K

chloride[1,2] On the molecular level both transitions are discontinuous—the molecule is either in one state or in another—and both are accompanied by a discrete change in the volume requirement of the molecule But while in deuterium chloride the transition from the low temperature phase with a single equilibrium orientation into the high temperature phase with twelve equilibrium orientations is accompanied by a volume change of about 1 9 per cent (in preparation) and the transition takes place within a temperature region much narrower than 1° K, in deuterium bromide the transition from the low temperature phase with a single equilibrium orientation into the middle phase with two equilibrium orientations is accompanied by a volume change less than 1 4 per cent and the transition of all molecules in the specimen is spread over a temperature range of some 20° K

Although the X-ray and neutron diffraction work described in this communication refers to deuterium bromide, the available experimental evidence suggests that the results obtained are applicable to the lower transition region of hydrogen bromide as well The investigation of a possible hysteresis effect both in the orthorhombic lattice parameters and in the composition of the solid solution over the lower transition region is in progress, so is the study of the crystal structure of both hydrogen and deuterium bromides in the upper transition regions

We thank M D H C Harris and the staff of the Dido reactor for supporting the neutron diffraction work at Harwell and C Hotston of Queen Mary College for technical assistance We also thank the Neutron Beam Research Committee and the Science Research Council for support

CHEMISTRY

Activation of Small Molecules by Transition Metal Ions and their Complexes

A QUALITATIVE, symmetry based view of the nature of the bonding in so-called π-complexes of unsaturated organic molecules with transition metals was put forward by Dewar[1] and Chatt[2] Simultaneous charge transfer from filled ligand orbitals to unfilled metal orbitals and from essentially non-bonding metal orbitals to antibonding ligand orbitals forms the basis of a model which successfully explains, for example, the change in the C—O stretching frequency of co-ordinated carbon monoxide compared with that of the free ligand The relative importance of "forward donation" and "back-donation" is not a matter for generalization; a theory of the bonding in Zeise's salt suggests that they are comparable[3] even for such a relatively poor acceptor as ethylene

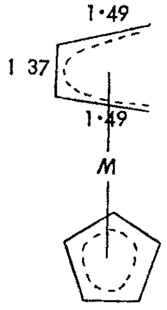
Largely as a result of crystal structure determinations during the past year or so, the geometries of co-ordinated ligands are now much better known As such, the implication of the Chatt–Dewar model—that the wave function describing the bonding in metal complexes will contain functions representing excited states of both the metal and ligands—can be examined in some detail by citing some of the structural data on carbon disulphide, acetylene, butadiene and oxygen complexes of transition metals in low valence states

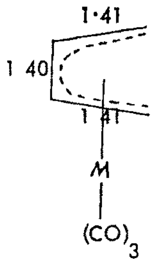
The structural analysis, by X-ray diffraction methods, of bistriphenylphosphine platinum carbon disulphide shows[4] the co-ordinated carbon disulphide to be non-linear, the S—C—S bond angle being 136°, the mean C—S bond length in the co-ordinated molecule is 1 63 Å Carbon disulphide, in its electronic ground state, is linear with a C—S bond length of 1 55 Å; the lowest excited state ($^3A_2$) of CS_2 is bent—the angle being 135° and the mean C—S bond length 1 64 Å (ref 5) These values are identical, within experimental error, to those found in the platinum complex A qualitative view of the change in geometry of carbon disulphide on excitation follows from Walsh's rules, the principal assumption of which is that a molecular orbital of an AB_2 system has lower energy if, on changing the bond angle at the central atom A, the molecular orbital changes from being built up from a p-type atomic orbital on A to one built up from an s-type atomic orbital on A (ref 6) That bending of the molecule lowers the π^* energy level by an electron volt or so presumably has an equivalent in the metal complex in so far as overlap of metal d-orbitals with this modified antibonding orbital is larger

Ingold and King[7] were the first to recognize that the geometry of a molecule in its excited state can be very different from that in its electronic ground state They found that the ^1A_u excited state of acetylene was *trans*-bent with a C—C—H bond angle of 120° and a C—C bond length of 1 38 Å, the *trans*-bent geometry is stabilized to some extent, compared with a *cis*-bent structure, through the minimization of non-bonded repulsion interactions. In both bistriphenylphosphine platinum diphenylacetylene[8] and hexacarbonyldiphenylacetylenedicobalt[9] the diphenylacetylene is *cis*-bent, the C—C—Ph bond angle averaging 140° and the C—C bond length 1·39 Å. In these complexes, non-bonded interactions with the metal will favour *cis*-bending. Kroto and Santry[10] have suggested that a *cis*-bent excited state of acetylene has a bond angle of 142° and a carbon–carbon bond length of 1·38 Å. These values are again identical, within experimental error, to those observed in the metal complexes.

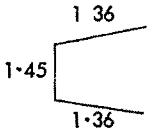
Unfortunately, there is no structural analysis available of ethylene co-ordinated to a transition metal which has the accuracy of the other determinations discussed here. This is a pity because there is some evidence that an excited state of ethylene has a geometry in which the molecule distorts into a pyramidal configuration for the atoms surrounding each carbon atom. This is the essential stereochemistry of the co-ordinated carbon atoms in bistriphenylphosphine platinum tetracyanoethylene[11] and racemic iron tetracarbonylfumaric acid[12].

The geometry of butadiene or quasi-butadiene complexes of metals has recently been reviewed[13]. The molecules fall into two distinct classes in which the butadiene fragment is respectively *trans* to the cyclopentadienyl or to the tricarbonyl group. The mean dimensions (±0·03 Å) of the butadiene ligand in these two examples are

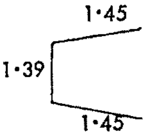




The Huckel molecular orbital predictions of the geometry of butadiene in its ground and lowest excited states are



Ground state

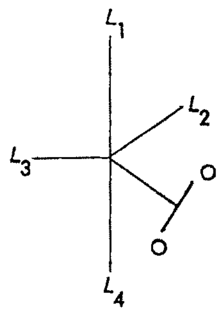


Excited state

Excitation leads to a change in bond alternation which is also found in the π-cyclopentadienyl metal butadiene complexes; the butadiene ligand *trans* to the tricarbonyl group has an intermediate structure, the geometry being roughly one corresponding to a superposition of the electronic ground and lowest excited states of the free ligand. These results are in keeping with the fact that the carbon monoxide ligand is a much better acceptor than π-cyclopentadienyl and are a useful reminder of the importance of the nature of *trans*-ligands in a complex (see later).

Discussion of the bonding of molecular oxygen to transition metals is not new, but four recent and precise structural investigations seem to add a good deal to the understanding of the problem.

The oxygen molecule in decammine-μ-peroxo-dicobalt monosulphate *tris*-(bisulphate)[14] bridges the cobalt atoms so that the Co—O—O—Co group is planar, the O—O distance being 1·31 Å. This is very close to the bond length in the O_2^- ion (1·28 Å) and a good deal less than that of the peroxide ion (1·49 Å). A quite different mode of bonding is found in some mononuclear iridium complexes[15–17]. The oxygen molecule occupies an equatorial



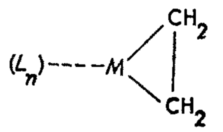
position in a trigonal bipyramidal arrangement around the iridium, the oxygen–oxygen bond length varying considerably. It is 1·30±0·03 Å when $L_1=L_4=Ph_3P$, $L_2=Cl$ and $L_3=CO$, 1·51±0·03 Å when $L_1=L_4=Ph_3P$, $L_2=I$ and $L_3=CO$ and, finally, in a chelating phosphine complex $L_1L_2=L_3L_4=Ph_2PCH_2CH_2PPh_2$, the O—O distance is 1·65±0·02 Å. This last distance, in particular, points out very clearly the shortcomings in discussions of the co-ordinated oxygen molecule in terms of $O_2{}^{n-}$ in this type of complex. If the bonding of oxygen is similar to those in the other π-complexes we could imagine that its structure would approximate one corresponding to the excitation

$$\pi^4\ \pi^{*2} \rightarrow \pi^3\ \pi^{*3}$$

in the free molecule. The precise amount of electron density transferred to antibonding orbitals on the oxygen through the intermediacy of the metal will depend on the remaining ligands in the complex. The two identified excited states arising from the $\pi^3\ \pi^{*3}$ configuration are the $^3\Sigma_u^{\pm}$—the weak Herzberg and stronger Schuman–Runge systems. The O—O distance in the $^3\Sigma_u^+$ state is 1·42 Å but is 1·60 Å in the $^3\Sigma_u^-$ state[18]; this latter value is close to the value in the bis-chelating phosphine complex. The variation in the O—O distance reflects the presence of the strong π-accepting carbonyl ligand in two of the complexes while the difference between the chloro- and iodo-complexes is a comment on their different donor and acceptor relations with the metal. Correlation effects are largely responsible for the difference in geometry between the $^3\Sigma_u^+$ and $^3\Sigma_u^-$ states of oxygen, but other correlation effects must intervene in the metal complexes—they are diamagnetic—and it is not obvious why it is the $^3\Sigma_u^-$ state which seems to approximate the geometry in the metal complex. The $^1\Sigma_u^-$ excited state of oxygen must have a similar internuclear distance to that of the $^3\Sigma_u^-$ state, but emphasis on the precise spin and orbital character of the co-ordinated ligand is misplaced to some extent. In all complexes, the metal ligand–bond energy must be more than comparable with ligand correlation energies.

It is interesting to examine the possible reasons for the two extreme types of bonding of oxygen—the σ-bonded species in binuclear complexes and the π-bonded arrangement in mononuclear systems (the number of mononuclear complexes with "unidendate" oxygen is likely to be very small indeed). When the transition metal ion is in a relatively high oxidation state, *d* orbitals will be considerably contracted compared with that in the zerovalent state; overlap with antibonding π* levels on the oxygen will be small and a σ-bonded arrangement of the kind found in the dicobalt peroxo-species will be favoured. In complexes such as the iridium ones mentioned earlier and bistriphenylphosphine nickel—and platinum—oxygen, the π-bonded arrangement will be energetically preferred.

The correspondence between a simple valence bond description of the structure of, say, ethylene complexes



where one imagines localized metal–carbon σ-bonds, the formation of a three membered ring and rehybridization of the carbon atoms, and that which emerges from a molecular orbital model, has been emphasized for the particular example of butadiene complexes[19] The valence bond model is less satisfactory because it is not useful in predicting the changes of geometry consequent on the variation of the *trans* ligands and/or substituents in the ligand itself

The ligand geometries can be discussed in terms of their polarization by the electric field of the metal ion, concepts such as the "softness" of the ligand can also be introduced but are not considered to be particularly helpful

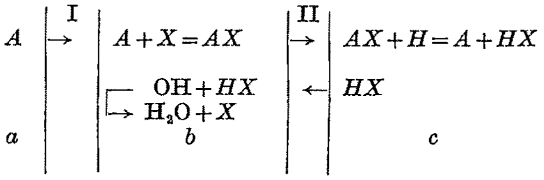
Transport of Ions against their Concentration Gradients in an Analogue System for Active Transport using Charged Membranes

To transport an ion against its concentration gradient requires energy, which in the biological membrane is supplied by metabolic or chemical reactions By the Curie–Prigogine principle of non-equilibrium thermodynamics, a vector flow of ions resulting from chemical coupling can only be achieved in an asymmetric membrane system[1-3] This is a consequence of the different tensorial order of the chemical and diffusional thermodynamic forces, which are scalar and vectorial, respectively Any membrane system which will transport ions against their electrochemical potential gradients using a chemical reaction as a driving force must therefore be asymmetric in the direction of active flow containing, for example, two membranes of different character through which the ions must pass

A common assumption in the theories of active transport is that the ion transported is at some stage attached to an activated carrier molecule which, on passing the membrane, is deactivated and releases the free ion The most remarkable feature of biological systems is the extremely high specificity of the active transport or pump mechanism for a particular ion, sodium, calcium and other ion pumps are well known In the simple physical model system described here, no attempt could be made to parallel such specificity or to use an ion for which a known biological pump exists The object was simply to construct a pump mechanism for an ion, using a known chemical reaction as a driving force, a specific carrier mechanism and charged membranes of known characteristics This exercise was thought to be useful because known biological pumps occur in very complex systems, where the physical nature of the membrane, the carrier mechanism and the metabolic driving reaction are not sufficiently well known

In outline the model pump consists of a two membrane system and contains three solutions, a, b and c Membrane I is a simple cation exchange membrane which is effectively impermeable to anions The cation to be pumped, A, is in the simple aquo or uncomplexed form in solutions a and c In b, however, it is complexed by the anion of a weak acid with which it forms an uncharged species AX There is thus set up a concentration gradient for the A ion across membrane I, driving this ion into solution b When A passes into solution b it is complexed by an excess of the ligand X so that effectively no free A is present Membrane II is designed to allow AX to pass through into solution c while retaining in b the anionic complexing ligand X, it is therefore a cation exchanger on the side facing solution b On passing through II, by diffusion, into solution c the complex AX is destroyed by strong acid, releasing the free ion A and associated weak acid HX To prevent back diffusion of A and free hydrogen ion, membrane II is an anion exchanger on the side facing solution c. The membranes are so designed that they will act as one way "valves" allowing only those ions involved in active transport to pass, retaining in b the complexing ligand and in c the transported A and hydrogen ion As this system operates, a concentration of associated HX will build up in solution c and back diffusion of this acid into b will become important Again we assume that membrane II is impermeable to ions but not to neutral species Because b contains the salt of the weak acid, it is alkaline If we therefore consider a system in which the pHs of b and c are maintained, a steady state will be reached such that the concentrations of HX in c and anion X in b will remain constant In such a system the net chemical reaction will be the reaction of hydrogen and hydroxyl ions to form water



In principle also it may be noted that the role of the weak acid may be replaced by a suitable redox system in which the anionic ligand is created in b and destroyed in c by the action of oxidants in b and reductants in c

In the simple physical system described here cupric ion was chosen as the ion to be actively transported, using as carrier the neutral acetate complex CuAc$_2$ In solutions a and c the copper ion is in the uncomplexed form in a medium of sodium nitrate Solution c, however, contains nitric acid initially 0 1 molar and acetic acid equal to that required in solution b The central compartment b contains the complexing acetate, present as sodium acetate, of equal concentration to the sodium nitrate of a and c plus 0 02 molar acetic acid to prevent copper precipitation as hydroxide Solution b has pH 9 The concentration of acetate was chosen as 0 46 molar to give maximum concentration of the complex $CuAc_2$ (ref. 4) which is in practice close to 50 per cent

Membrane I is a commercial cation exchanger (AMF *C* 103, supplied by American Machine and Foundry Co) and is highly impermeable to anions Membrane II is a supported membrane of hydrous zirconia held in the pores of a plastic PVC frit Zirconia is an amphoteric ion exchanger which has cation exchange properties in base and anion exchange in acid solutions and negligible exchange characteristics in neutral solutions[5] The bathing solutions *b* and *c* are, respectively, basic and acidic, so the zirconia behaves as a sandwich of cation and anion exchangers It was chosen in preference to a pair of commercial exchangers because of its rather more open structure Such a double membrane will effectively present a barrier to both anions and cations while allowing "normal" permeability to uncharged species, this permeability being some function of the membrane structure and independent to a first degree on the membrane charges

The experimental apparatus consisted of a 'Perspex' cell with three compartments, *a*, *b* and *c*, provided with mechanical stirrers, and with working volumes of 115 ml each. These compartments were separated by membranes I and II, which had cross-sectional areas of 5 cm^2 Experiments were carried out at 20°±3° C Copper ion was analysed spectrophotometrically in 2 molar ammonia solution at a wavelength of 6300 Å[6], sodium by flame-photometry and total cation content by ion exchange for hydrogen ion and titration

Two preliminary experiments were carried out on the reduced system solution *a*, membrane I, solution *b*, and solution *b*, membrane II, solution *c* In the first experiment, the total copper concentrations in *a* and *b* were equal at 0 02 molar Analysis showed that cupric ion left solution *a* and entered *b* at a rate which was almost steady during a period of days, while sodium was transported in the opposite direction, from *b* to *a*, in amounts equivalent to those of copper ions This was verified by a constant total cation analysis of solution *a* during the experiment, indicating that transport of one copper ion from *a* was accompanied by transport of two sodium ions into *a* These results are summarized in Table 1 and Fig 1

In the second experiment, a small increase of 3 per cent in the total copper ion in *c* was observed after a period of 2 days and no net sodium ion transport was detected Analysis of the acid content of *c* showed that twenty times as much acid was used up in this period as would be required to destroy the copper complex transported, but it was equal to the decrease in the base concentration of *b*. This consumption of acid and base results from the interaction of these ions to form water within the zirconia membrane

To achieve an almost steady state concentration of copper ion in *b* during experiments on the complete cell, the initial total concentration of copper in *b* was increased to 0 04 molar Over a period of 7 days there was copper transport from solution *a* to *c*, during which the *p*Hs of *b* and *c* were maintained approximately constant by the addition of 20 mequiv. of sodium hydroxide or nitric acid in a total volume of 2 ml added in small amounts over the period of the experiment After 5 days, solution *a* was considerably depleted of copper and was replaced with fresh original solution The total copper concentration in *b* remained constant in the last 2 days of the experiment so that the number of copper ions leaving solution *a* equalled those reaching *c* in the same period Analysis for sodium again showed that sodium ion transport from *b* was coupled with copper transport in the opposite direction The removal of copper ion from solution *a* leaves that solution negative with respect to *b* and sets up an electrical potential gradient across the membrane I The gradient can only be reduced by sodium transport with the electrical gradient from *b* to *a* because this cation exchanger is effectively impermeable to anions Analysis of the sodium contents of *b* and *c* shows that there is a small sodium flow from *c* to *b* by salt diffusion through membrane II These results are summarized in Table 2 and Fig 1.

Table 1

Time (days)	Copper ions transported (mequiv)		Sodium ions transported (mequiv)	
	a	*b*	*a*	*b*
0 89	−0 712	+0 666	—	—
3 90	−2 42	+2 56	−2 5	−2 5

Table 2

Time (days)	Solution (ml)	Concentrations of copper (molar)			Copper ions transported (mequiv)		
		a	*b*	*c*	*a*	*b*	*c*
0	115	0 0200	0 0400	0 0200	0	0	0
4	115	0 0100	0 0450	0 0245	−2 30	+1 15	+1 04
5	110	0 0080	0 0470	0 0255	−2 74	+1 59	+1 26
6	105	0 0183	0 0480	0 0265	−3 17	+1 79	+1 47
7	100	0 0166	0 0480	0 0275	−3 44	+1 79	+1 67

In this simple system it is therefore possible to use a net chemical reaction to cause the directed flow of cupric and sodium ions : copper ion by virtue of its ability to form a neutral acetate complex and sodium by non-selective electric coupling with the copper ion flow The section membrane I, solution *b*, membrane II, parallels the function of the biological membrane, at least in principle, and contains the essential asymmetry required by the Curie–Prigogine principle In the case of the frog epithelium, which actively transports sodium ion, the bathing solutions need not be other than chemically identical so that the membrane itself must contain all the ingredients necessary for the specific active transport of sodium ion and so include within itself the whole metabolic and carrier chemistry Unpublished results of H H Ussing have shown that the frog epithelium has the property of a degree of electrolytic rectification , it conducts electric current more easily in one direction than in the other This is also a general property of a sandwich of cation and anion exchangers

In this simple analogue system zirconia plays the same part because absorbed salt depletion or concentration within the membrane causes its resistance to increase or decrease according to the direction of current In the initial solution conditions of the experiment on the com-

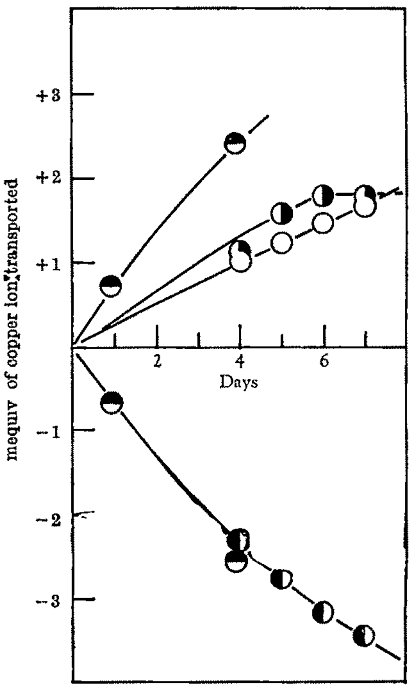


Fig. 1 ◓, Experiment I, ◐, *a* experiment III, ◑, *b* experiment III, ○, *c* experiment III posite membrane system a current of 18 or 26 mamp flowed between copper electrodes in *a* and *c* under a constant 6 V supply dependent on the direction of the applied field This analogy may point to the more general validity of this type of ion barrier in the biology of active transport

I thank Professor Hans H Ussing of the Institute of Biochemistry of Copenhagen, where this work was carried out, and the Royal Society for a travel and maintenance grant

Detection and Location of N-Methylamino-acid Residues in N-Acyloligopeptide Methyl Esters by Mass Spectrometry

IN a previous communication[1] we described a procedure for complete N-methylation of peptide –CONH– groups in oligopeptide derivatives A mixture of methyl iodide and silver oxide in dimethylformamide was used as the reagent This reagent is also capable of methylating –OH or –SH groups It was shown that the N-acyloligopeptide methyl esters exhibited enhanced volatility after methylation, and that the permethylated products were more suitable for mass spectrometric sequential analysis of their amino-acid residues

It has not been possible to detect and locate with certainty the presence of an N-methylamino-acid residue in a peptide by mass spectrometry because the mass number as well as the elemental composition of a given amino-acid and its N-methylated lower homologue (for example, leucine and N-methylvaline) are the same We describe here a method of solving this problem, making use of the mass spectrometric shift technique[2]

A comparative study of the mass spectra of an N-acyloligopeptide methyl ester and its permethylated derivative provided information on the presence as well as the location of originally existing N-methylamino-acid residues in oligopeptide derivatives (1) The increase in molecular weight after complete N-methylation indicates the number of methyl groups introduced in the molecule and thus the number of peptide –CONH– groups (together with –OH, –SH groups, if present) in the oligopeptide derivative before methylation (2) Each amino-acid residue which had gained a methyl group revealed itself by an increase of 14 mass units recognizable from the peaks arising by peptide bond cleavage (3) An amino-acid residue with its peptide nitrogen originally methylated or fully substituted showed no change in mass number after methylation (unless it contained other methylatable functional groups), and thus its position could be determined

To illustrate the foregoing approach we have chosen fortuitine (I) as a model compound This naturally occurring peptidolipid[3] is composed of nine amino-acid residues including two N-methylleucines and one proline

The sequence of nine amino-acids in fortuitine was deduced by mass spectrometry and was reported previously[4] Comparison of the mass spectra of fortuitine (I) and its permethylated derivative (II) discloses that the molecular weight has increased by 84 mass units on methylation This corresponds to six (6 × 14, Val_3Thr_2 Ala) methyl groups being incorporated in the molecule, in agreement with the proposed structure of fortuitine. It is evident from the mass spectra (see Table 1 and Fig 1) of fortuitine and permethylfortuitine (II) that only the mass of each newly N-methylated amino-acid residue has increased by 14 mass units after methylation This therefore allows us to locate exactly the two N-methylleucine units in fortuitine (I)

For $n = 20$										

The mass spectra were obtained with an AEI-*MS*9 instrument equipped with a direct inlet system and operating at 70 eV

* Fortuitine (I) gave a molecular ion peak at m/e 1359 ($n = 120$)[4] Under our conditions fortuitine (I) or permethylfortuitine (II and III) did not give the molecular ion peaks but instead showed the M-120 peaks corresponding to the loss of two molecules of acetic acid

† The numbers underlined represent the nominal mass of amino-acid residues which are not methylatable

‡ Peaks for $n = 18$ are observed 28 mass units lower

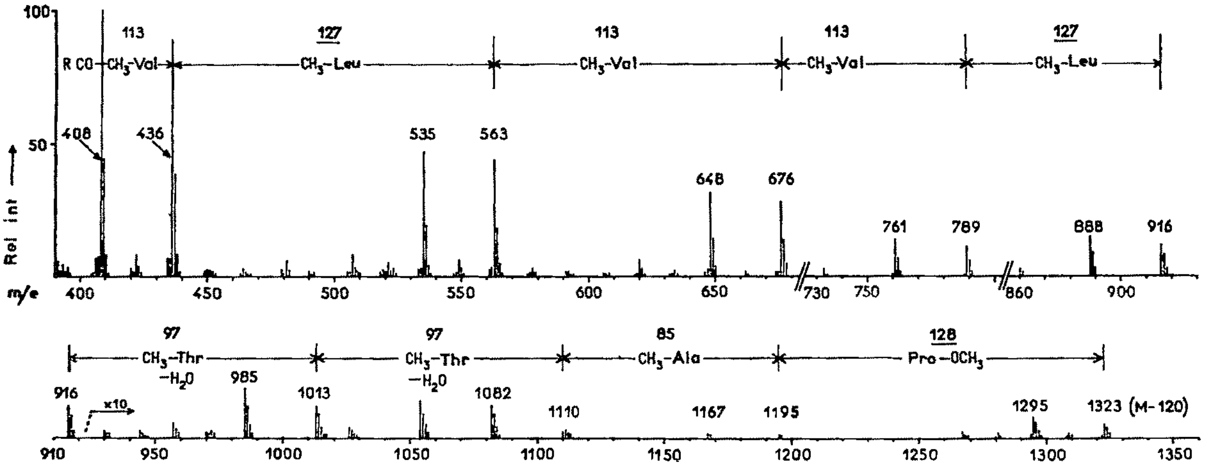

Fig 1 Mass spectrum of permethylfortuitine $R = CH_3(CH_2)_n$—where $n = 18$ or 20

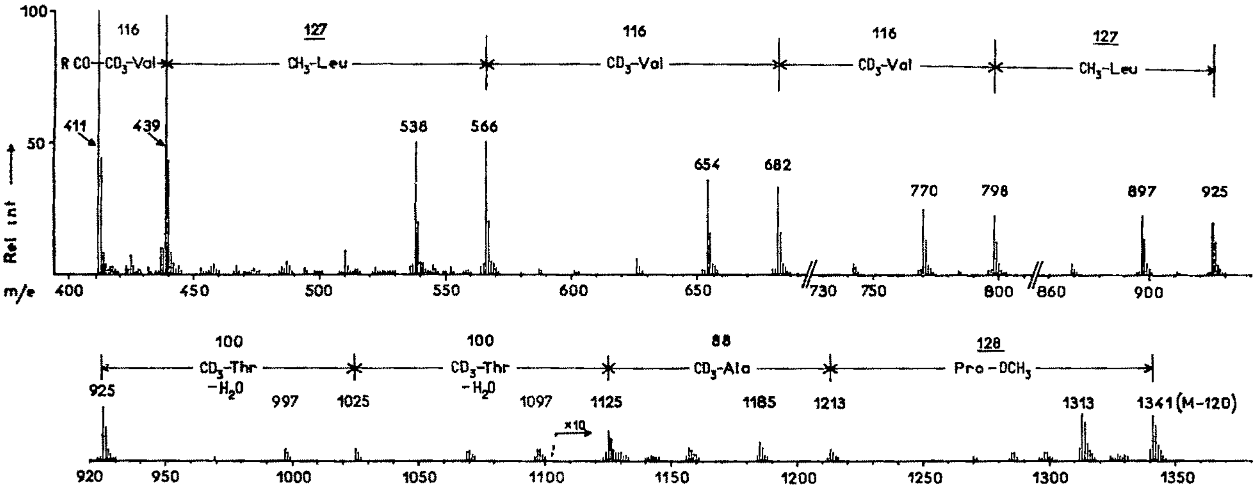

Fig. 2. Mass spectrum of perdeuteriomethylfortuitine $R = CH_3(CH_2)_n$—where $n = 18$ or 20

This procedure cannot, however, be used for oligopeptide derivatives which do not give mass spectra before methylation, for example, the heptapeptide derivative[1]

$$\text{Ac-Gly-Phe-Tyr-Thr-Pro-}\underset{\underset{\text{Ac}}{|}}{\text{Lys}}\text{-OMe}$$

In such cases, the N-acyl peptide methyl ester may be treated with a mixture of trideuterio methyl iodide and silver oxide in dimethylformamide to obtain the corresponding perdeuteriomethylated product Comparison of the mass spectra of the permethylated and the perdeuteriomethylated derivatives would indicate a shift of 3 mass units (CH_3 against CD_3) for each N-deuteriomethylated amino-acid residue Such a shift would not be observed if the amino-acid residue did not originally contain any methylatable hydrogen

In order to check this approach we prepared perdeuteriomethylfortuitine (III) The observed increase of 18 mass units (3 × 6) in the molecular weight of (III) [as compared with (II)] established the incorporation of six deuteriomethyl (CD_3) groups The amino-acid sequences, including the position of the original two N-methylaminoleucine residues as well as one proline, can now be unequivocally recognized from the mass spectrum (see Table 1 and Fig 2) of perdeuteriomethylfortuitine (III)

We wish to point out that it may be possible to find the location of the N-methyl residues originally present from the mass spectrum of the perdeuteriomethylpeptide derivative alone Nevertheless, a comparison with the mass spectrum of the permethylpeptide derivative makes it simpler to recognize the position of the original N-methylamino-acid residue in the peptide chain

We trust that this method will find successful application to natural compounds of unknown structures

We thank Mme E. Vilkas of this Institute for the gift of fortuitine which made this study possible.

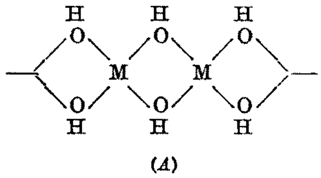
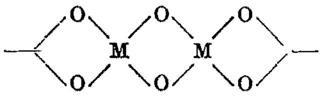
Mechanism of Bonding in Aqueous Nickelous Nitrate–Magnesium Oxide Cements

THE low temperature cementation effects in the nickelous nitrate–water–magnesium oxide system have only recently been reported[1] When aqueous solutions of nickelous nitrate are added to magnesium oxide powder, a basic salt with the idealized formula of $Ni_2(OH)_3NO_3$ forms and bonds the magnesium oxide aggregate together. A mechanism for the formation of the basic salt and its subsequent bonding to the magnesium oxide grain surfaces is suggested

When the salts of metallic elements are dissolved in water or in other solvents, aggregation of the cations will occur in suitable conditions[2] This process ultimately leads to the formation of polynuclear complexes, and in those formed in aqueous solution the metal ions are linked by means of hydroxide bridges, as in (*A*), or oxide bridges, as in (*B*)



(*A*)



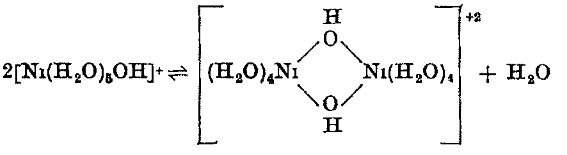
(*B*)

In aqueous solutions, the conditions necessary to bring about the formation of these complexes involve increasing the *p*H of the solution by the addition of OH^- ions, or increasing the concentration of metallic cations in the solution[2]

When an aqueous solution of nickelous nitrate is added to the magnesium oxide aggregate, the water reacts with magnesium oxide to form magnesium hydroxide at the surface of the grains This reaction increases the *p*H of the cement solution causing nickel hydroxide polymers to form

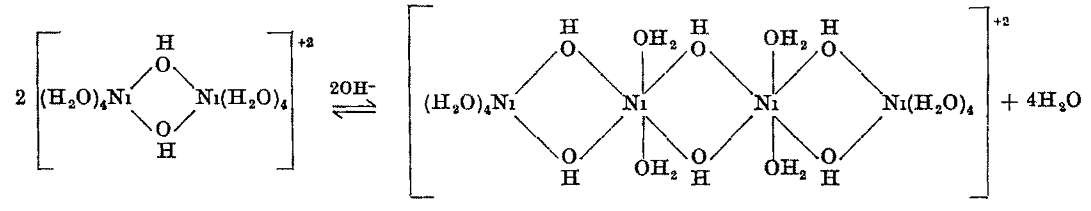
Cuta *et al* [3] and Veprek-Siska[4] have found that solutions of nickel salts are capable of such aggregation Veprek-Siska gave the following equations for aggregation of nickel in aqueous solutions

$$[Ni(H_2O)_6]^{+2} + H_2O \rightleftharpoons [Ni(H_2O)_5OH]^+ + H_3O^+ \qquad (1)$$



(2)

This process can be extended so that nickel hydroxide polymers of infinite length can be obtained A continuation of reaction (2) is shown below in reaction (3)



(3)

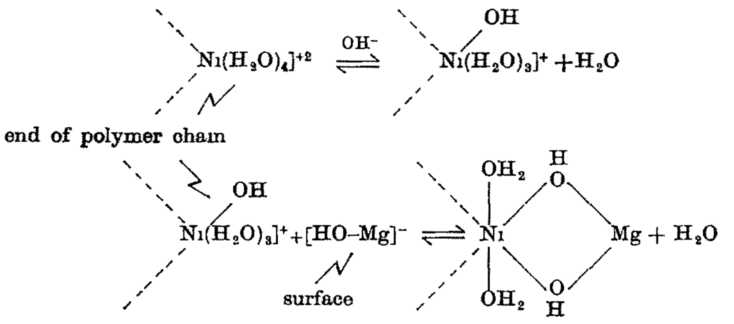
The idealized reactions (1)–(3) lead to the formation of nickel hydroxide in solution The same reactions would be applicable to the formation of basic nickel nitrate

All the known basic nickel nitrates consist of layers of nickel hydroxide interleaved with nitrate ions[5] Then the nickel hydroxide polymers would form as shown in reactions (1)–(3) with the nitrate ions positioned between these hydroxide polymers This conclusion is also consistent with what is known about the structures of the hydroxyhalides of nickel which are considered to be $Ni(OH)_2$ layers with halide ions and water molecules randomly arranged between them[6]

The water in the cement solution is either bound on the surface of the magnesium oxide or held in the co-ordination sphere of the nickel ion The product of reaction (3) contains only four nickel ions This polymer can be extended as long as nickel ions are available in the solution

The bonding of the basic nickel nitrate to the surface of the magnesium oxide grains can be ideally visualized as follows First, water in the cementing solution reacts with magnesium oxide to form magnesium hydroxide on the surfaces of the grains Then, as this reaction proceeds, the basic nickel nitrate precipitates from solution and reacts with the magnesium hydroxide that is forming

Consider the end of a nickel hydroxide polymer chain from reaction (3) The end of this molecule reacts with the newly formed magnesium hydroxide surface layer in the following manner



(4)

(5)

Thus this surface reaction stops the polymerization of the salt at the surface of a magnesium oxide grain and bonds the basic nickel nitrate to the magnesium oxide This process repeated in many places in three dimensions causes the cementing action

To confirm the presence of a magnesium hydroxide layer between the bonding phase and the aggregate, single crystals of magnesium oxide were reacted with the cementing solution Later the resultant hardened cement phase was stripped off the single crystals to expose the magnesium oxide–cement interface These interfaces were then examined using X-ray diffraction techniques It was found that a magnesium hydroxide layer was present between the magnesium oxide matrix and the cement phase

Reactions (1)–(3) show how nickel hydroxide or basic nickel nitrate polymers can form in solution It is thought that the heat given off by the magnesium oxide + water reaction at the aggregate surface causes the precipitation of the basic salt and its subsequent bonding to the magnesium oxide grains[1] If magnesium oxide powder is treated with water, dried and then mixed with the nickelous nitrate solution, no cementation occurs If the resultant mixture is dried in an oven at 250° F, $Ni_2(OH)_3NO_3$ will form, as determined by X-ray diffraction analysis These dried samples, however, could easily be crushed by hand pressure indicating that the magnesium oxide grains are simply mechanically entrapped in the basic salt matrix For cementation to occur, the nickelous nitrate solution must be added to unreacted magnesium oxide grains

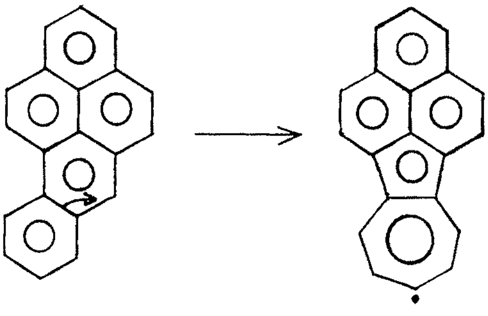
Possible Formation of an Azulene-type Radical obtained on Heating 3,4-Benzpyrene

IN an earlier communication[1] we reported that 3,4-benzpyrene (I), an agent known to cause cancer and one of the components of tobacco smoke condensate, when heated to about 200° C gives rise to free radicals, which give well resolved electron spin resonance spectra This communication describes further work on these free radicals

The relevant spin resonance spectrum (Fig 1*a* and *b*) could be completely simulated (Fig 1*c*) if the following splitting constants were assumed $a_1 = 1\ 135$ gauss (two protons), $a_2 = 1\ 562$ gauss (two protons), $a_3 = 2\ 362$ gauss (two protons), $a_4 = 5\ 196$ gauss (two protons), $a_5 = 5\ 469$ gauss (two protons), $a_6 = 8\ 271$ gauss (one proton) The less well resolved spectrum, reported previously (see Fig 3 of ref 1), could also be simulated using the same splitting constants but using a larger linewidth (200 mgauss)

The similarity between Fig 1*b* and *c* shows that the two proton splitting constants in each of the five pairs of coupling constants are equal to within at least half the linewidth (0 025 gauss) A species, which possesses five pairs of equivalent interacting protons, must have appreciable symmetry Limiting the search for a likely species to radicals which do not contain other than five, six or seven-membered rings, the data indicate the formation of radical II (derived from azuleno[1,2,3-cd]phenalene) which may be formed by a single bond rearrangement as follows



I II
